

Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

SUMMARY

OUR monthly supplement on "Electrical Engineering in Mines" is included in this issue. It opens with an abstract of a Paper on "Electricity in New South Wales Collieries," by Mr. E. K. Scott. Reports are given of discussions on electric winders before the Newcastle and Manchester Sections of the Institution of Electrical Engineers, at the latter of which a Paper by Dr. E. Rosenberg was read. A note is given on the possible cause of the explosion at Bolton, and discussions before two branches of the Association of Mining Electrical Engineers on a Paper by Mr. R. R. Smith on the care of underground plant are reported. Some notes are also given on mining patents published during December.

AN important Paper read last month by Mr. J. G. Lucas before the Institute of Post Office Engineers described some important investigations on the life of primary cells used for telephone purposes. Mr. Lucas found as the result of a long series of experiments that the substitution of powdered manganese dioxide for the granular form enormously increased the useful life of the cells, and he also recommended the employment of manganese chloride instead of salammoniac. He advocates the employment of the wet cell with the powdered depolariser for practically every purpose for which primary cells are now employed in telephony. (Page 3.)

THE Bills of electrical engineering interest which have been deposited in Parliament for the 1911 Session include a large number of proposals relating to the use of trolley omnibuses. Another Bill seeks to draw the District Railway and the allied tubes in closer union, and the Metropolitan Electric Supply Co. ask for powers to acquire the Acton electricity undertaking. (Page 4.)

A SHORT article takes up the subject of electric train lighting further, and contains a short summary of the state of affairs on British railways in this respect. (Page 4.)

A LETTER from Mr. G. Wilkinson points out that very little economy is to be derived from the use of a dimming resistance switch. (Page 5.)

AMONG the specifications published by the Patent Office on Thursday was one by the Felten & Guilleaume Lahmeyerwerke A.-G. for a subsidiary short-circuited winding on the stators of electrical machines to counteract the field fluctuations which induce currents in shaft and bearings. The Bergmann Elektricitätswerke A.-G. cover a process for effecting simultaneously the sealing in of the leading-in wires of metal filament lamps and the fusion of the central pillar to the foot of the bulb. Opposition has been entered to the grant of a patent to J. Neu for an arc lamp of the supported carbon type with a pivoted stop, and a patent by W. E. Bullock for an electrical treatment of iron and steel to prevent rusting is also opposed. (Page 7.)

Hosted by Google

IT has been decided to run the two power stations in Leicester as one undertaking. The Hammersmith Council have applied to the Board of Trade to appoint an arbitrator in their dispute with the London United Tramways Co. The Chairman of the Worcester Electricity Committee has resigned owing to differences with the Council as to municipal wiring. (Page 8.)

EXTENSIONS involving new boilers, a 3,000-kw. turbo-alternator, mains, transformers, &c., to a value of £25,253, are recommended at Hammersmith. A number of new petrol-electric omnibuses on the Stevens system are to be put in service in London. (Page 8.)

THE capital of the Aron Electricity Meter Co. is to be increased by £100,000. The reduction of capital of the Cleveland & Durham Electric Power Co. from £1,000,000 to £700,000 is confirmed. (Page 10.)

Colliery Fatality.—Conflicting evidence was given at the inquest on December 13th, on F. Toseland, a motor attendant, who was killed at the Bond's Main Colliery of the Staveley Coal and Iron Co., Derbyshire, on the previous day. It appears that the deceased mounted a platform alongside a three-phase motor for driving a stamper, in order to oil the motor. He was heard to shout, and was then found in an unconscious condition holding on to some bare wires just above the motor. One witness, who attempted to pull him off, stated that he received a shock, while another, who did the same, said he received no shock. The first witness said that the switch was off and the wires should have been dead, while both stated that the motor was not running, and was making no noise. W. E. Chappell, electrical engineer to the company, stated that he had found the motor and gear in good condition, and that the switch must have been closed, or partly closed, for the deceased to have received a shock. A post-mortem examination of the body showed disease of the lungs and indications of pleurisy, and the cause of death was stated by the doctors to be heart failure, "quite possibly due to electric shock," though it might have been due to natural causes. The jury returned a verdict of accidental death by electric shock.

ARRANGEMENTS FOR THE WEEK

SATURDAY, JANUARY 7TH.

Association of Mining Electrical Engineers: Yorkshire Branch.
5 p.m. At Royal Victoria Hotel, Sheffield.

TUESDAY, JANUARY 10TH.

Institution of Electrical Engineers: Manchester Students' Section.
7.30 p.m. At Manchester School of Technology. "Large Gas Engines," by G. D. L. Horsburgh.

Institution of Electrical Engineers: Glasgow Section.
8 p.m. At 207 Bath Street.

WEDNESDAY, JANUARY 11TH.

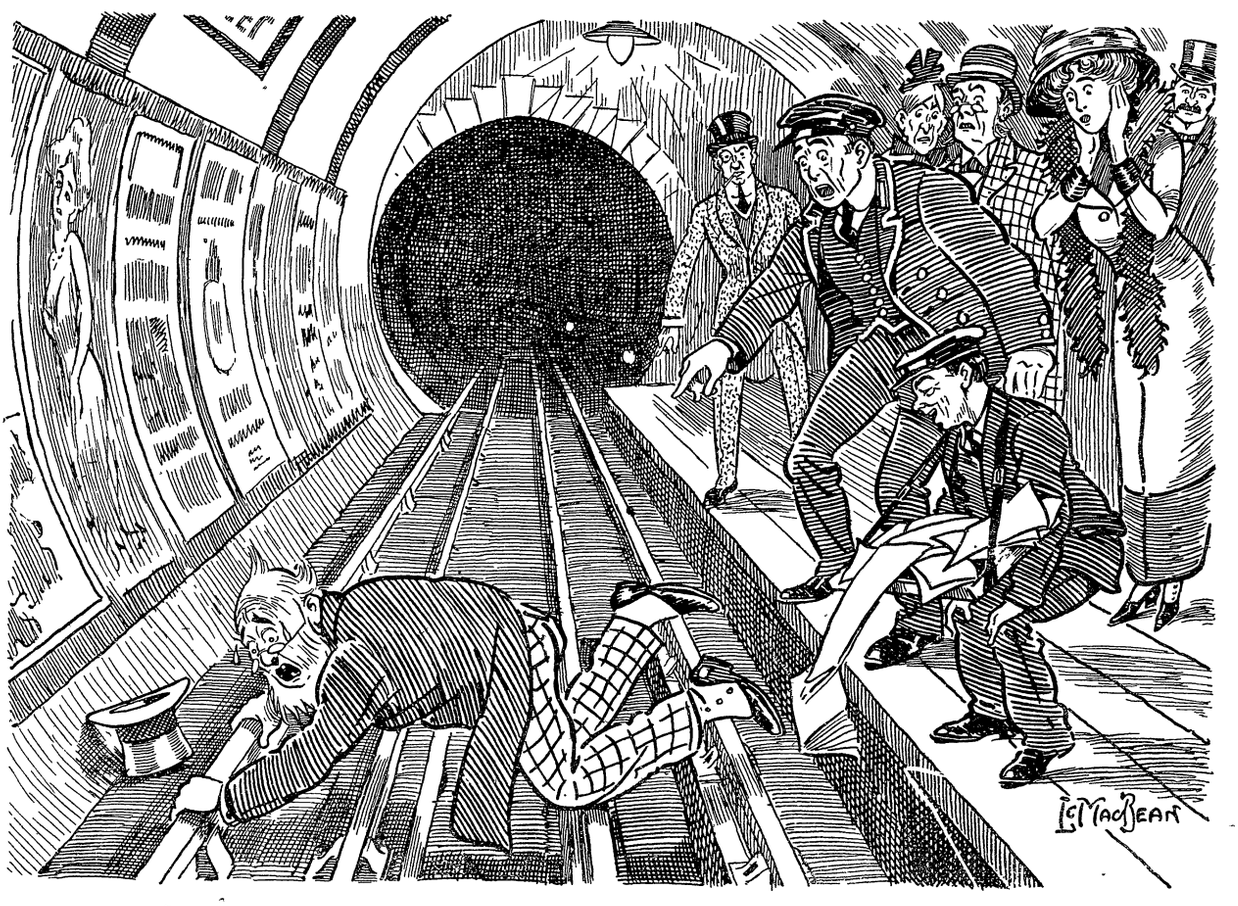
Institution of Electrical Engineers: Yorkshire Section.
7 p.m. At University, Leeds. "Radio-Telegraphy," by Dr. H. Stroud.

Institution of Electrical Engineers: Birmingham Section.
7.30 p.m. At University. "Merz-Price and other discriminative protective apparatus for A.C. circuits," by K. Faye-Hansen and G. Harlow.

Association of Engineers in Charge.
7.30 p.m. At St. Bride's Institute. "Engineering Plant in Institutions," by W. T. Hatch.

THURSDAY, JANUARY 12TH.

Institution of Electrical Engineers.
8 p.m. At Victoria Embankment. "Submarine Cables for Long Distance Telephone Circuits," by Major W. A. J. O'Meara. Adjourned discussion.



Institution of Electrical Engineers: Dublin Section.
8 p.m. At Royal College of Science.

Junior Institution of Engineers.
7.30 p.m. At Royal United Service Institution, Whitehall. "Depreciation of Buildings and Machinery," by H. F. Donaldson, C.B.

FRIDAY, JANUARY 13TH.

Electro Harmonic Society.
8 p.m. Smoking Concert, at Holborn Restaurant.

The Institution Dinner.—The annual dinner of the Institution of Electrical Engineers, which was postponed from December owing to the general election, will be held on Thursday, February 2nd, in the Grand Hall of the Hotel Cecil. There will be a reception at 7 p.m.

Station Official to old gentleman who has fallen on track: "If yez cannot take yer hands off the live rail, sorr, just thry an' lift yer knees off the other one an' ye'll break the circuit."

Hosted by Google

PRIMARY CELLS FOR TELEPHONE PURPOSES

IN spite of the continual extension of the common battery system, and the introduction of secondary batteries wherever practicable, a large number of primary cells are still employed for telephone purposes, and there is no doubt that their use in large quantities is likely to continue. There are at present no less than 105,000 No. 1 Leclanché cells of the porous pot type in use in connection with minor and small exchanges for signalling and miscellaneous purposes. 43,000 six-block agglomerate cells are being employed chiefly for exchange operators' speaking batteries; and for subscribers' speaking batteries 29,000 two-block agglomerate cells and 18,600 (Y type) dry cells are in use, the latter taking the place of the agglomerate cells in situations in which wet cells cannot be conveniently maintained. In addition to these, 11,000 dry cells (Z type, square) of a larger size, and 26,500 bichromate cells of the porous pot type, are employed where heavier currents are required. These figures apply to cells in use by the British Post Office only; if those employed by the National Telephone Co. were added, the totals would be greatly augmented.

In view of these statistics, it is remarkable that so little has been done hitherto in the direction of investigating whether the patterns of batteries employed with but little modification for numbers of years are really the most suited for the purpose, and therefore great interest attaches to a Paper read by Mr. J. G. Lucas before the Institute of Post Office Electrical Engineers last month, in which a long and elaborate series of investigations (carried out by him in conjunction with Mr. Andrew Fraser) are described.

Stated briefly, the main conclusion arrived at is that by the substitution of powdered manganese dioxide for the comparatively large granules of manganese dioxide usually employed, the ordinary porous pot Leclanché cell is enormously improved, so much so, in fact, that there is little doubt that cells so constructed will largely displace all other patterns, both wet and dry, and will frequently enable No. 3 size cell to replace larger cells of the ordinary type. Fig. 1 (Chart 42 of the Paper) gives the results of discharging two No. 1 Leclanché porous pot cells, exactly similar in every respect, except that in one the manganese dioxide is powdered, and in the other merely granulated. The weights of material were identical, and in both cases the cells were discharged for five hours a day and six days a week.

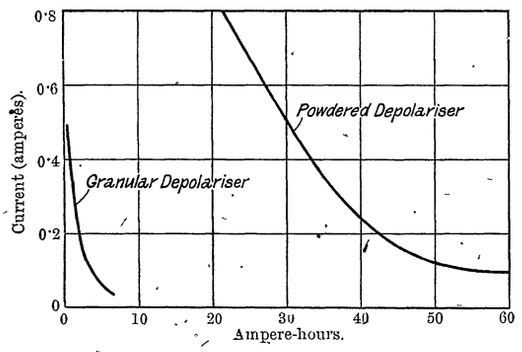


FIG. 1.—EFFECTIVE AMPERE-HOURS (ALLOWING A MAXIMUM FALL OF 33 PER CENT. IN THE VOLTAGE) OBTAINED FROM No. 1 LECLANCHÉ CELLS WITH THE SAME WEIGHTS OF MATERIALS. CELLS DISCHARGED FOR 5 HOURS PER DAY, 6 DAYS PER WEEK.

Fig. 2 (from tests plotted in Chart No. 3 of the Paper) is equally convincing. The tests were taken under conditions corresponding to working conditions. The cells were connected to the circuit from 10.30 a.m. to 4 p.m. for five days of the week and for 2½ hours on Saturdays. On Sundays they were allowed to rest, and this day is not included in the curve, which only represents the actual running days. The cells were considered discharged when the voltage had fallen to 0·925 volts, or if the resistance had risen to 3 ohms per cell. The voltage measurements recorded were taken on Mondays, Wednesdays, and Fridays at 10.30 a.m. and 4 p.m., and the ampere-hours were measured accurately by a copper voltameter. Curves 1, 2, and 3 relate to a two-cell No. 1 Leclanché battery of the ordinary porous pot type, discharging at an average current of 41·6 milliamperes; to simply comparisons, we have divided the reading by two, so as to give the mean volts and resistances per cell. Curve 1 gives the open-circuit voltage taken in the morning immediately after each period of rest; Curve 2 shows the open circuit voltage in the evening immediately after each period of discharge; and Curve 3 is the resistance of the cell. After the test was complete, the depolariser in the porous pot of one of the cells was removed, ground to powder and replaced, and another test was taken without renewing the salammoniac. Curves.

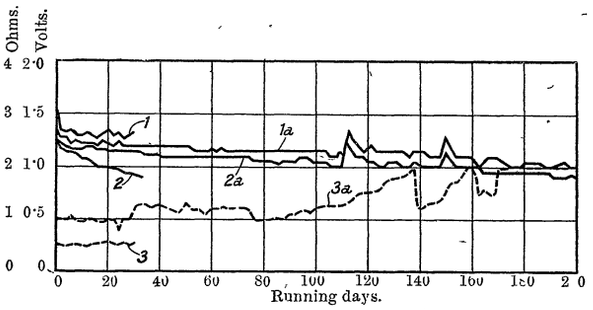

FIG. 2.—VOLTAGE AND RESISTANCE CURVE OF No. 1 LECLANCHÉ CELL, WITH THE DEPOLARISER SUBSEQUENTLY POWDERED.

Curves 1 and 1a = Open-Circuit Voltage (Morning).
" 2 and 2a = " " (Evening).
" 3 and 3a = Resistance of Cell.

1a, 2a, and 3a give the results of this test, and show conclusively the longer life and the smaller drop of voltage at the end of each discharge period. Mr. Lucas estimates a decrease of the cost of maintenance and renewals to one-seventh in the case of discharge rates of 40 milliamperes, and even greater economy with cells for larger discharge rates.

Fig. 3 (Chart No. 38 of the Paper) shows the effective ampere hours obtained from a number of different classes of cells, including dry cells and bichromate cells. Mr. Lucas attributes the larger number of ampere-hours obtainable in the case of the Siemens than in the Fuller dry cell to the fact that the Siemens depolariser is more finely powdered, and thus forms a more compact mass, so that the gases escape slower and carry off less moisture; the cell, therefore, does not dry up so quickly. The occasional bursting of the Siemens cells, he says, may be partly due to this cause, and partly to the formation of crystalline bodies within the zinc canister. Up to a certain point, it is seen that the effective ampere-hours of the dry cells actually rise with increased current; this is due to the rise in resistance (due to drying up) making it necessary to discard the cell after it has been in use for a certain period, and at the low discharge rates the ampere-hours developed in that period are of course less. The superiority of the Siemens cell is also seen; it has a far longer life than the Fuller on the lower discharge rates, and this is also clearly brought out in one of the other series of curves in the Paper. The bichromate cell shows a similar effect to the dry cells, due to the gradual diffusion of the liquids through the porous pot; in these cells, the lower limit of voltage is taken to be 1·8, and as the initial voltage is about 2·1, the permissible drop is, therefore, 15 per cent., instead of 33 per cent., as in the case of the Leclanché cell, which is allowed to fall from 1·4 to 0·925 volts. These values are the ones which are followed in practical working.

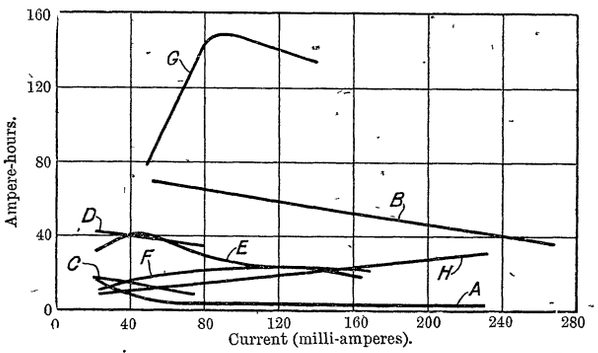

FIG. 3.—EFFECTIVE AMPERE-HOURS FROM DIFFERENT TYPES OF CELLS AT VARIOUS DISCHARGE RATES FOR 5 HOURS PER DAY, 6 DAYS PER WEEK.

A = No. 1 Leclanché Granular Depolariser.
B = " " Powdered "
C = 2-Block Agglomerate.
D = 6-Block "
E = Siemens Dry (Y size).
F = Fuller " "
G = Z Size Dry.
H = 3-Pint Bichromate.

The Paper also gives some interesting particulars with regard to the substitution of manganese chloride for ammonium chloride as the electrolyte in the wet Leclanché cell. The author has done this to prevent the evolution of ammonia

Hosted by Google

gas. The absence of this gas renders it unnecessary to ventilate the boxes of subscribers' batteries, and therefore diminishes evaporation and "creeping," so that a considerable saving in maintenance costs is expected.

In comparing the costs and efficiencies of the various batteries for subscribers' speaking purposes, Mr. Lucas stated that experts in determining telephone transmission efficiencies were unable to perceive any loss due to the resistance of the usual two-cell speaking battery rising from 0·5 ohm to 4 ohms, and that even at 6 ohms internal resistance the loss was only just appreciable. This, he pointed out, has an extremely important bearing upon the question of the most economical type of battery to be used for subscribers' speaking sets, and he estimates that the total working costs may be reduced to half by employing cells with powdered depolarisers in place of the existing two-block agglomerate battery, and to nearly one-third as compared with dry cells. The cell he proposes has already been subjected to experimental trials with satisfactory results. It is a No. 3 porous pot Leclanché, with rod zincs, manganese chloride solution, and powdered manganese dioxide and carbon. The resistance is 1·5 ohms per cell, and Mr. Lucas sees no reason why a pair of such cells should not be maintained for five years (as compared with four years for the agglomerate type) without the resistance of the two cells rising above the 6-ohm limit, and without special maintenance costs.

ELECTRICAL BILLS IN PARLIAMENT

THE outstanding feature of the Electrical Bills of interest which have been deposited in Parliament for the 1911 Session is the large number of proposals relating to the use of trolley omnibuses. In all there are some fourteen Bills of this nature. The incorporation of new companies is proposed for Malvern (capital £24,000), Matlock (£15,000), Rotherham, Maltby and district (£60,000), the Western Valley of Monmouth (£60,000), Oldham and Saddleworth (£50,000), Croydon and district (£60,000), and Macclesfield and district (£100,000). In the last case the supply of electricity for lighting and power purposes will also be undertaken. The Rotherham Corporation also take powers in their omnibus Bill to use trolley omnibuses over several of the same routes that are scheduled by the Rotherham company mentioned above, and borrowing powers to the extent of £81,000, repayable in 30 years, are asked for, so that they are virtually competing Bills. The following Councils and companies also propose to construct trolley omnibus routes :—Aberdare, Newcastle, Northampton, Chiswick (in conjunction with the London United Tramways Co.), Lanarkshire Tramways Co., Brighton, Preston and Hove Omnibus Co. The last-mentioned proposes to run trolley omnibuses from Brighton to Worthing, and another company has scheduled the same route for tramways with some portions on the "trackless" system. The promoters of the latter undertaking include the Hon. Arthur Stanley, Mr. J. M. Henderson, and Mr. R. W. Watson, the capital being £210,000. In all the Bills relating to trolley omnibuses the Board of Trade is to be given similar powers to those which they possess in connection with tramways. The standard clause giving the Postmaster-General the right to use the posts carrying the overhead wires which is now common to tramway undertakings is also included in all the Bills.

The periods proposed for the repayment of loans by the Local Authorities shows considerable variation : *e.g.*, Rotherham wish to borrow £81,000 for 30 years, while Newcastle asks only 20 years for £14,100. Northampton divides its small loan into two portions, one for vehicles repayable in 15 years, and the other for electrical equipment repayable in 30 years.

Some interest attaches to the Bill of the Rhondda Urban District Council, which seeks powers to supply electrical fittings, apparatus, etc., on hire, and to wire premises, as there is no reference to the work being given to contractors.

There are only a few Bills of interest relating to London and the most important is a proposal to form a joint committee of the Metropolitan District Railway Co. and the London Electric Railways Company, to simplify the organisation of management of these undertakings, by practically completing their amalgamation. Proposals for a junction between the Bakerloo and Hampstead tubes at Charing Cross, and for the extension of the Bakerloo to Paddington are again brought forward; the former scheme, it will be remembered, was rejected last year owing to the possibility of danger to the foundations of the Hotel Metropole. Another interesting clause in this Bill is to empower the District, Metropolitan, Central London, Great Northern and City, City and South London Railway Co., and any other railway company, to enter into agreements for the supply of electrical energy. The Metropolitan Electric Supply Co. have deposited a Bill for acquiring the electricity undertaking of the Acton Urban District Council on the payment of £5,000 in cash under certain conditions, and paying also interest and sinking fund charges on outstanding loans.

The London, Tilbury and Southend Railway Co. seeks powers to acquire land for a generating station in Essex, and to raise £750,000 additional capital, and to sell their existing rolling stock with a view to purchasing rolling stock for the electrical operation of their lines. The Central London Railway Co. propose to extend their lines from the Wood Lane terminus to join the authorised Ealing and Shepherd's Bush Railway on the Great Western Railway Company's line. The London County Council Tramways Bill involves an expenditure of £829,030 upon tramways, and £352,010 on street improvements, and the Metropolitan Electric Tramways seek to construct a new bridge over the River Lea in order to link up with the Walthamstow tramway system, and also to construct lines in Enfield, Willesden, and Edgware.

There is also a large scheme for constructing an outer circle railway, starting at Feltham in Middlesex, and passing through the north-eastern outskirts of London, terminating at Tilbury with a total of 57¾ miles. No mention is made in the Bill of the method of traction which is to be adopted. The capital of the company is £5,500,000, and the promoters include the Hon. Arthur Stanley.

The following Corporations propose tramway extensions :—Belfast (£210,000), Hull (£92,000, which includes provision for enlarging their power station), Manchester (£7,850), Newcastle (£74,000), Southampton (£20,000), Rotherham (£51,700), Northampton (£111,000). The South Lancashire Tramways Co. propose to construct two small lengths of tramway in Farnworth and Worsley, to enter into running power agreements with the Wigan Corporation, to supply Atherton Council with electricity, and to supply electricity to premises on their tramway routes.

The Winchester Corporation will purchase the Winchester Electric Light and Power Co. at £91,000 plus the repayment of capital expenditure, although the company's Provisional Order has not yet expired. The Sidmouth Gas and Electricity Supply Co. is to be incorporated, with a capital of £30,000.

TRAIN LIGHTING

WE referred in our last issue, in connection with the recent railway accident at Hawes Junction, to the serious mistake made by some railway companies in not displacing gas lighting entirely by electric lighting in order to avoid the added danger of fire in cases of collisions and derailment. The matter has been taken up in various other quarters, and several articles have appeared in the daily Press drawing attention to the risk. Letters have called upon the Board of Trade to make regulations forbidding the use of gas on trains, but it has been pointed out by *The Times* that the actual imposition of such a regulation is outside their powers, although official recommendations can, of course, do much in that direction, and an Act of Parliament drafted by the Board of Trade for the purpose could certainly be passed. In the meantime, it is of interest to look around and see the extent to which electric lighting has already been and is being adopted on British railways. The first line to adopt electric train lighting exclusively was, we believe, the London, Chatham & Dover, many coaches on which were converted directly from oil to electric lighting on the Stone system. The South-Eastern Co.'s rolling stock was gas lighted, however, so that the trains on the amalgamated South-Eastern & Chatham Railway have still many coaches lighted with gas. The carbon filament electric lamps are gradually being replaced by metal filament lamps, and, needless to say, the electrically-lighted carriages are sought out in preference by the passengers. Among the railways whose trains are all electrically lighted are the North Staffordshire & Furness Railways. Almost the whole of the London & North-Western stock is now fitted with electric light, the change from gas having been commenced some ten years ago. The bulk of the stock of the Great Central has electric light, and the same applies to the London, Tilbury & Southend and the Great North of Scotland. The Great Northern are fitting most of their new stock, including dining cars, with electric light, and this is also being done, although at a slower rate, on the Great Western. Electric light is also being introduced gradually on the Caledonian and North British Railways. On the Midland Railway, only a small proportion of trains are electrically lighted, and the company appear to favour incandescent gas. This is also the case on the London & South-Western. The Great Eastern, the London, Brighton, & South Coast, the Lancashire & Yorkshire, and the Glasgow & South-Western Railways use gas in all except a few cases, such as dining cars and special expresses, and on the Highland Railway all the lighting is by gas or oil. As regards economy, it is difficult to get reliable figures, but there is no doubt that the adoption of the metal filament lamp has so lowered the cost of electric lighting in trains that there now can be little, if any, margin in favour of gas. The matter, however, is one of safety, and not of saving of fractions of a penny per train mile.

ELECTRICAL ENGINEERING

IN

MINES

Correspondence on any of the subjects dealt with in this Supplement is cordially invited from our Readers.

The Editor is willing to insert letters over a *nom de plume*, but Correspondents should send their full names and addresses in all cases.

Letters should be addressed, "THE EDITOR, ELECTRICAL ENGINEERING, 203–206 Temple Chambers, London, E.C.," and should reach this office by the 21st of the month.

Correspondents are requested to write on one side of the paper only.

ELECTRICITY IN NEW SOUTH WALES COLLIERIES

A PAPER by Mr. E. Kilburn Scott with the above title has been discussed recently by several branches of the Association of Mining Electrical Engineers. Coal was first discovered in Australia in 1787, and the colliery industry has steadily grown. In 1908 (the year before the strike), over nine million tons were raised. The bulk of this comes from New South Wales, but coal is also mined in Queensland, Victoria, and West Australia. In the last-mentioned district electric coal-cutters are used a good deal.

The principal collieries in New South Wales are in the northern district. The Paper gives a table of particulars of those known to be electrically equipped. These are over 50 in number, and the installations range up to 475 kw. In only six cases is alternating current employed, the remainder being continuous current. In some cases the plant is for lighting only, but power is used in 18 mines for coal-cutters, in 11 mines for haulage, in 9 for fans, and very generally for pumping.

All these northern pits have adopted 250-volts continuous current, in order to employ standard American coal-cutters. Work under construction includes a generating station for the J. & A. Brown group equipped with two 1,000-kw. mixed pressure Willans turbines. Some of the D.C. stations are being changed over to A.C., such as those at Aberdare. In the Southern District, South Bulli has a 450-kw. 3-phase installation at 2,300 volts, cables at this pressure being taken through the main roads to the principal haulages. The Bellambi Colliery was the first to adopt 3-phase plant. The generating sets are 100-kw., 2,300 volts, 60 cycles, and there is a Tirrill regulator to keep the pressure steady. One of the haulages is 35 h.p. and the other 50 h.p., the pressure being stepped down at each of these from 2,200 to 220 volts. The cable is Siemens 3-core 19/16 insulated with paper, lead covered and armoured with steel tape. The water in the mine is slightly acid, so the steel tape is covered with bitumenised fibre.

Many of the older American engines for belt drive are being taken out in favour of British direct coupled sets. Mr. Scott remarks that there is no doubt whatever that British makers of coal-cutters would be preferred to the American for any extension plant if only they would produce machines suited for room and pillar work.

A favourite method of fixing cables in New South Wales mines is to tie them on to petticoat insulators which have right angle and coach screw stalks. The stalks are screwed into the supporting timbers of main roads and headings, or where convenient they screw into wooden plugs driven into the roof.

The type of coal-cutter most used is the chain breast pattern, of which the Jeffery, Goodman, Morgan-Gardner, and Sullivan machines are examples. Percussion pick machines are much used in New South Wales, but they are nearly all driven by compressed air. An electrically driven percussion machine called the Morgan-Gardner is, however, in use to a small extent. It has a reciprocating piston, actuated by a spring and cam, the spring striking the blow and the cam drawing the piston back. The cam is in turn driven by a motor, having a vertical spindle.

The bar coal-cutter as made by Mavor & Coulson has got a good foothold in Australia. These machines are in use at Mount Kembla Colliery, New South Wales; Stockton Borehole Colliery, New South Wales; Invincible Colliery, New South Wales; Zambunna Colliery, Victoria. At Mount Kembla one of these machines produced over 20,000 tons in its first year.

Briefly the reason for the appointment of the Committee of Inquiry into the use of electricity in mines was the unrest of the miners in some of the Maitland collieries. This was particularly the case at Hebburn Colliery in the South Maitland District, where the strike started. The first record of trouble was the burn out of a trail cable reported to the manager on October 24th, 1906. From then on there were various minor accidents, until August 23rd, 1907, when another trail cable burnt out in the safety lamp district. The miners of the whole Northern District then stopped, and one of the conditions they asked was that the electrical machines should be taken out. The committee appointed by the Government consisted of: His Honour C. E. R. Murray, District Court Judge; Professor T. W. E. David, Professor of Geology at the University of Sydney; O. W. Brain, M.I.E.E., Chief Electrical Engineer of Government Tramways and Railways; A. E. O. Sellers, Manager of the Bellambi Colliery; and Jas. Curley, a practical miner, to represent the men.

After examining various witnesses, the Committee issued an interim report on November 29th, and two of the clauses were: (*a*) A considerable number of electrical burn outs have taken place in the Hebburn Colliery. (*b*) The matter of the use of electricity in this mine will not be on a satisfactory basis until a complete set of regulations governing the installation, operation, and testing of every portion of the equipment has been adopted and is enforced. This will involve the obtaining of some additional testing apparatus by the management.

The Committee then proceeded to examine further witnesses and make inquiries regarding the drafting of special rules and starting of examinations.

The Paper reproduces some of the evidence given by the author himself before the inquiry, and some of the questions set in the examination for the mine electrician certificate in New South Wales. The number of certified mine electricians in New South Wales is given as 40.

It should be noted that the New South Wales rule *re* examinations provides that, not only must the mine electrician have a certificate, but that the assistant electrician must have one as well. The rule reads: "No person shall, after the expiration of twelve months from the coming into force of these rules, be allowed to act as mine electrician or as an assistant electrician, unless he shall be the holder of a certificate of competency issued by the Department of Mines, authorising him to act, in the first case as a mine electrician, or in the second case, as an assistant electrician." Engine drivers are also examined by the Government. At the University of Sydney, all the students in the Mining School have to take one year's course in Electrical Engineering.

ELECTRIC WINDERS

THE discussion on electric winders by the Newcastle Local Section of the Institution of Electrical Engineers, reported in "ELECTRICAL ENGINEERING IN MINES," December 1st, 1910, p. cxxv, was continued on Monday, December 12th. Mr. T. CAMPBELL FUTERS said that he had no doubt that electric winding could be made as safe as steam, but he objected to many electric winders on account of the complications. In steam winders, the parts were visible and easily adjusted or repaired. They could run for years without repair, and accidents were few and chiefly due to fatigue of the metal. Could the same be said of electric winders? The initial cost of an electric winder was greater, and it was questionable if it could be run so economically that the greater prime cost was justified. Most German collieries had adopted the Koepe pulley, as it was recognised that the inertia of the heavy drum was disadvantageous to electric winding. The objections to the Koepe pulley were (1) the danger of both cages falling on breakage of rope; (2) the tendency of the rope to slip; (3) the difficulty of lowering or raising greater weights than the pulley was designed for; (4) the large size of pulley necessary to deal with heavy loads; and (5) the low limit of speed, and therefore inflexibility of colliery output. In Germany the life of ropes was limited by law, and usually they could not be greased or oiled. Provided the difficulty of the inertia of the cylindrical drum could be got over, he thought the Koepe system was not worth considering. In modifications of the system, the rope was balanced by the spiral drum (a cure worse than the disease), or flat hemp ropes were wound on a light bobbin. The difficulty was not so much the balancing of the ropes, but the inertia of the moving mass. The weight of the drum depended on its diameter, and this was determined by the depth of the pit and the angling of the pulleys, as it was not considered good practice to let the rope coil on itself. The minimum diameter of the drum was usually 100 to 120 times the diameter of the rope, but with a flexible rope might be much less than this. Both diameter and width of drum could probably be considerably reduced with safety. If the net load were made a maximum and the speed a minimum, the acceleration peak would be largely reduced, and the rope would be less strained. An objection to the Ilgner system was the heavy first cost, especially when the winding motor was direct connected. There was now no objection to gearing, even in the largest winders, and the size of the motor could thus be reduced. Considering the cost of the gearing, however, it was doubtful if the initial cost could be reduced. It was, he thought, questionable whether the Ilgner arrangement was justified, and he suggested a method utilising the stored energy of clutched and unclutched weights. As regards control, the Ward Leonard system was the best. On the whole, however, he thought it better to retain steam winders and utilise the exhaust in a low-pressure turbine. As to whether a colliery should generate or buy from a supply company, if the colliery company could find the capital and the load factor was favourable (the Eight Hours Act tended to aid this) it was undoubtedly cheaper to generate at the colliery.

In a written communication, Mr. F. ANSLOW (Glasgow) said that he was not prepared to agree altogether with Mr. Wilson that supply from a company would render electric winding commercially efficient. The margin in cost between the two systems of winding was very small. Centralised supply rendered the problem one of overall efficiency rather than efficiency of the winder only. With regard to the turbine plant with one generator for the winder and another for general colliery purposes referred to by Mr. Hooghwinkel in the previous discussion, his own firm had devised a similar arrangement with the addition of a flywheel for peak loads, which was better than relying on the boilers. Another plant installed by his firm in South Wales consisted of an Ilgner winder at a new pit two miles from the generating plant. All steam-raising plant and engines were dispensed with at the new pit.

Mr. MATTHEW KIRBY submitted two sets of figures for steam winding engines at Bowburn Colliery and Park pit respectively. The former was a cross-compound engine (put down in July, 1907), non-condensing, working without superheat at 150 lbs. per sq. in., cylinders 13¾ in. and 23 in. by 32 in. stroke. The drum was 8 feet diameter, and the depth of shaft 636·6 feet. Two tubs containing about 10 cwts. each were wound in each cage. There was a balance rope. The engine made the lift in 25 to 27 seconds, the tubs being changed in about 5 seconds. One hundred tons could be raised per hour. During the period over which figures were taken, the coal raised per hour was 20·28 tons. Summarised, the cost in pence per hour of boilers (depreciation and interest at 10 per cent.) was 1·97d.; labour, 2·124d.; coal, 9·67d.; stores and repairs, 0·205d. This gave a total of 13·989d. per hour, or 1·084d. per ton per 1,000 feet. The cost in pence per hour for the engine was, for interest and depreciation (10 per cent. of capital), 5·78d.; labour, 10·76d.; stores and repairs, 0·87d., giving a total of 17·41d. per hour, or 1·35d. per ton per 1,000 feet. The gross cost was therefore 2·434d. per ton per 1,000 feet. The Park pit engine (put down in December, 1907) was a similar one. The cylinders, 19⅜ in. and 32 in. by 60 in.; drum, 9 feet in diameter; steam at 150 lbs. per sq. in.; non-condensing. There was no balance rope. The shaft was 400 feet deep, and two tubs, each of 30 to 35 cwts., were wound at a time. The engine could raise about 300 tons per hour. During the period over which the figures were taken 35·2 tons were wound per hour. The figures gave a cost in pence per hour for the boilers (10 per cent. of capital), 3·878d.; labour, 6·5d.; coal, 16·8d.; stores and repairs, 0·172d. This gave a total of 27·350d. per hour, or 1·66d. per ton per 1,000 feet. Similarly for the engine the cost in pence per hour for capital charges was 10·2d., for labour 7·0d., and for stores and repairs 0·59d., a total of 17·79d., or 1·08d. per ton per 1,000 feet. This gave a gross total of 2·74d. per ton per 1,000 feet in this case. Neither gave low costs, but they were actual examples of steam practice.

Mr. H. A. COUVES (Newcastle-on-Tyne Electric Supply Co.) said that there was a large demand for electric winders of small output; many collieries in the North were working 700 to 800 tons per day, winding from 600 to 700 feet. Colliery companies were well advised not to put in electric winders if current had to be generated privately, but the case was different where a public supply was available. Many old steam winders still working ought to have been scrapped long since; the installation of electric winders in their place would not be expensive, as most of them could be three-phase geared machines. He knew of one small Ilgner set drawing coal from 140 feet, and taking a little over 50 units per 100 tons; in another case of a three-phase geared machine winding from 180 feet, the current consumption per 100 tons was about 80 units. Where a company had spent considerable capital on economical steam winders for large outputs, a case existed for installing exhaust turbines, but not otherwise.

Mr. SCHUIL drew attention to the omission by Mr. Wilson of buffer storage-batteries for equalising the load. It was not everywhere that supply companies could be found having plant of such capacity that a 1,500 h.p. load could be thrown on and off without causing voltage troubles. At Clausthal, a battery capable of giving 200 amps. for one hour kept the 'bus-bar volts within 2½ per cent., notwithstanding peaks of nearly four times the current mentioned. The battery need only be small, provided that heavy rates of charge and discharge could be carried. Many speakers mentioned the low power-factor of a three-phase induction motor at starting. Such rotors had non-inductive resistances in series, and therefore, unless the resistance was cut out too quickly, the power factor should not be low. Dr. Rosenberg had confirmed this view by giving figures from some large three-phase Westinghouse induction motors. In a 1,600 h.p. winding motor, 98 r.p.m., 50 cycles, the power factor was 74 per cent., 80 per cent., and 79 per cent., when the starting torque was normal and 160 per cent., and 200 per cent. respectively of normal torque. In a 1,000 h.p. motor, 300 r.p.m., 50 cycles, the power factor was 91 per cent. and 90 per cent., with starting torque equal to and double the normal torque respectively. In a 700 h.p. winding motor, 58 r.p.m., 25 cycles, the power factor was 84 per cent. and 85 per cent. for starting torques equal to and double the normal torque. Hence the power factor in starting was in general quite as good as, if not better than, during running at normal full load.

Mr. W. C. MOUNTAIN (Ernest Scott & Mountain, Ltd.) mentioned some figures just given by Mr. Hudspeth before the Institute of Mining Engineers for electric winders at the Deutschland, Castellengo, and Heinitz mines, Upper Silesia. To compare results he had obtained estimates from one of the first makers of steam winders in the country. Briefly, the cost of the electric winder at Deutschland, including generating plant, was £9,750. That of the equivalent steam plant, including boilers for the same duty, was £3,500. The cost of winding per 100 tons with electric drive was 24s. 9d., while with steam it was 9s. 3d. Taking the Castellengo plant, the cost of electric plant as above, was £9,750. The cost of the equivalent steam plant was £4,000. The cost of winding per 100 tons with electric drive was 16s. 2d., while with steam it was 7s. 7d. In the case of the Heinitz winder, the cost of electric plant was £9,050. The cost of steam plant for the same duty was £6,330; hence the cost of winding per 100 tons with electric drive was 15s. 10d., while with steam it was 11s. 9½d. The first two were Siemens-Ilgner winders, and the third was on the Ward Leonard system fed direct from a D.C. generator on a turbine which also drove a three-phase machine for the ordinary colliery supply. At another colliery winding 4,200 tons of coal per 15-hour day with one pair of steam engines from a depth of 1,626 feet, the cost per 100 tons, including 5 per cent. interest, 10 per cent. depreciation, labour, stores, coal, &c., was 5s. 2d. Thus in many cases electric winding could not compete with steam winding. There were cases, however, where electric winding, especially for small duties, could effect considerable saving. He would like to ask Mr. Schuil what was the life of the batteries he mentioned. In one case a battery had been installed at a German colliery for this purpose, but after nine months it was put out of commission as the plates were damaged, and an equaliser set used instead.

Mr. SCHUIL said that the batteries at Clausen had been in operation, he believed, for 2½ years, and a similar plant at the Carnegie Steel Works for 2 years.

Mr. WILSON replied briefly, and the discussion was closed.

CONTROL OF ELECTRIC WINDERS

IN a Paper read before the Manchester Section of the Institution of Electrical Engineers on December 6th, Dr. E. Rosenberg (British Westinghouse Electric & Manufacturing Co.) dealt with the control of electrically driven main winders. The author pointed out that, besides starting and stopping ordinary loads, it is often necessary to lower unbalanced loads, in which case the motor, if it be used at all, must work as a generator. If no tail rope is used, and the load on the up-going cage is just balanced by the load on the down-going cage, then the rope weight will, in the first half-trip, exercise a positive, and in the second half a negative torque, and the winding machine has at first to act as a motor and then as a brake.

In the case of Ward-Leonard control, as long as the speed of the motor-generator is kept constant, the shunt regulator of the generator determines its E.M.F., and the speed of the constantly excited winding motor will attain a value which gives an E.M.F. of the winding motor only slightly higher, because a slight difference will give rise to a circulating current of sufficient magnitude to balance the torque impressed by the load. Assuming that the exciting voltage is kept constant, that there is no flywheel and no artificial slip in the motor-generator, that the slip of the induction motor at full load is 2 per cent., that the controlling machine has a drop in voltage from no load to full load of 5 per cent., and that the winding motor has a drop in speed of 5 per cent. from no load to full load, then the difference of the motor speed between no-load torque and full-load torque will be approximately 12 per cent. If the winding motor has to exercise a negative torque of half the value of the normal working torque, the difference in speed will grow to 18 per cent. This difference of 18 per cent. grows in proportion if the controller lever is put into a position for a low speed. For half excitation the lifting speed for normal load will be about 39 per cent. of the full (no-load) speed and the lowering speed for a load which would require half-braking torque will be about 56 per cent. of the full speed. If an Ilgner set with increased slip is used, or if the excitation is not constant, the differences will be greater. It is therefore necessary to use a speed indicator, and not to depend upon a positive relation between the position of the control lever and the speed of the winding engine. With Ward-Leonard control, the movements of the lever in order to come to rest are nearly the same whether the motor is driving or driven, and a very great braking torque can be obtained.

With a D.C. shunt motor fed direct from the 'bus-bars, and provided with combined series and shunt regulation, braking is done most effectively within the range of shunt regulation without any additional apparatus, as the motor will work as a generator if driven from outside and return power to the line. For a given position of the shunt regulator (with the series resistances cut out) the motor when exercising half full-load brake torque will develop a speed approximately 7 per cent. higher than the motoring speed for the same position. When resistance is inserted in the armature circuit, the E.M.F. of the motor working as a generator will have to be considerably greater than the 'bus-bar voltage in order to return power through the resistance to the line. Thus 80 per cent. motor speed at full load would correspond to 110 per cent. generator speed for 50 per cent. brake torque, and a position for creeping speed of the motor, say 5 per cent., would allow a generator speed for 50 per cent. brake torque of 148 per cent. Consequently, such controller positions are not suitable for lowering loads, and regenerative control should only be used with the controller in "full-on" position. Regenerative control cannot be used to slow down the motor at the end of the trip. The controller has to be moved into the "off" position and the mechanical brake applied, or it may be moved beyond the "off" position and the first steps for the lifting movement used. In case the speed throughout the lowering trip has to be kept lower than the speed which the motor develops with all the armature resistance cut out, for instance, for lowering of men, counter-current must be used during the whole trip. Regular braking with counter-current is a very safe, but naturally wasteful, method.

With a polyphase induction motor, the conditions are analogous to those of a D.C. shunt motor (without shunt regulator) fed direct from the 'bus-bars. If the rotor is short-circuited, the machine will, for a slight increase in speed, act as a generator and return power to the line. The generating speed on half-load would be only 3 per cent. above the full-load motor speed. Liquid controllers, however, are seldom completely short-circuited, and, therefore, the speed difference might be nearer to 6 or 8 per cent. To brake the motor down to lower speeds, counter-current is required. Driving the motor at over-synchronous speeds with resistance inserted (controller in lowering position) would here also cause too high a speed to be reached.

Dr. Rosenberg then described the use of a D.C. motor as a dynamic brake by disconnecting the armature from the line, and connecting it to a resistance. If the machine is constantly excited, the braking torque will be in direct proportion to the speed of the motor, and in inverse proportion to the resistance. It would be necessary at first to increase, then to reduce the resistance, or a constant resistance could be used which would only limit the speed of the lowering load, and other means could be used to bring the load to rest at the end of the trip. To use an induction motor as a dynamic brake, the stator is connected to a low-voltage D.C. supply and the three slip-rings to a three-phase resistance. The machine then represents an A.C. generator with stationary field, the exciting winding of which is distributed in the slots, and with a rotating polyphase armature connected to resistances. As the air-gap is small, the armature reaction is exceedingly high, and this has a very important influence, because it is only for small armature reaction that (at constant speed) the torque will be in inverse proportion to the resistance. As soon as the armature current exceeds a certain limit a reduction of the resistance will even reduce the braking torque.

The author then dealt with the different ways of connecting a three-phase winding to a D.C. supply, and necessary value of current to produce the same magnetic conditions as at full-load with A.C. supply. A method of determining the relations between torque, speed, and resistance under these conditions was given, and tests on a 30-h.p. motor were described. It was shown that the torque always increases with increased D.C. excitation, whereas for a decrease of resistance the torque might be increased or decreased, dependent upon the momentary speed. Consequently, it is not safe to use the variable resistance of the controller for braking, as the driver may easily overshoot the mark in trying to make the brake more effective, and then he would not be able to stop the load. It would, however, be possible to change the resistance automatically in proportion to the frequency of the rotor currents. For a constant excitation and a constant resistance in the armature there exists a critical speed up to which the torque increases and after which the torque goes down with increased speed. If the exciting current and the resistance are high enough, however, it is possible to ensure that the brake torque wanted is well below the obtainable maximum torque, and that the speed wanted is well below the critical speed. For stopping mechanical brakes would be supplied.

Turning to eddy-current brakes, the author pointed out that there is an essential difference between those with copper discs and those with cast-iron armatures. The latter had the important advantage that there was a steady increase in torque with increasing speed, and no critical speed after which the torque diminished as with copper disc brakes. His explanation was that the virtual resistance of the cast-iron armature cannot be considered as a constant value, but that it increases with increased periodicity. He considers that for low speeds the flux penetrates the whole depth of the cast-iron armature, and that with increased speed, and therefore increased voltage, the current density near the surface increases, and shields the deeper parts, so that the currents crowd on the skin of the armature. Therefore, with increasing periodicity, the resistance of the eddy-current path increases, and this also has the effect that the resultant flux does not tend to fall off, since in order to maintain the current with the increased resistance, a higher E.M.F. is required. The eddy-current brakes as used in connection with large hoisting engines are able to deal with continucus trips of unbalanced loads, and it is possible to regulate the speed without use of the mechanical brake down to a very low value. The field is excited from D.C. 'bus-bars which are fed by a motor-generator and on which a storage battery is floating; therefore the brake is also available in case of failure of the main supply current, and in such cases the excitation is switched in automatically.

Concluding, the author states that it is impossible to say which is the best system of control. For lowest power con-

Hosted by Google

sumption, if the starting and braking periods and the periods of trips with reduced speed are of long duration, the Ward-Leonard system might prove the most efficient. With different starting and running conditions the simple A.C. motor system might be the most efficient, and in other cases might be preferred on account of its lower initial cost. If current is charged on a flat-rate basis, an equaliser would be out of place, because it not only increases the initial costs, but also the total current consumption. A charge on the maximum demand system, on the other hand, will turn the balance in favour of equaliser systems. The question also whether any inducement is offered to the power consumer for a good power factor might turn the balance in a given case from the direct-coupled slow-speed A.C. winding motor to the Ward-Leonard system with high-speed motor-generator.

Discussion.

Mr. J. S. Peck (Westinghouse Co.), referring to the use of an A.C. motor excited by direct-current, said that an objection to the system was that it was not possible to brake with counter-current while the motor was generating. With the eddy-current or with any other type of external brake, such as a water brake, it was possible to use the mechanical brake, counter-current, and the external brake simultaneously. The external brake also gave a highly satisfactory method of lowering at reduced speed.

Mr. W. Cramp asked if an induction motor with a variable number of poles could be used. It might be employed as a brake down to the speed corresponding to the largest possible number of poles. With regard to D.C. motors, why could not the compound motor be used, cutting out the shunt and using the motor as a series generator for braking purposes?

Mr. Frith said that he had used an eddy-current brake with an external iron wheel and an alternator field for ordinary test work to absorb the load of motors, and had also found that the torque increased with the speed. He thought the path of the eddy-currents was so undefined that their armature reaction on the field magnets was only very slight. To direct the eddy-currents he had tried slotting the iron and putting in a copper squirrel cage winding in good electrical contact throughout with the iron, but had had better results by employing the copper end rings only without the axial bars; these seemed to offer an inducement to the eddies to travel right across the face of the brake.

Mr. S. J. Watson said that he had been thinking what the effect would be on a generating station supposing there were about a dozen collieries connected up without any equalising load arrangements, and that their peaks all came on at once. Each would have a maximum load of about 1,500 kw., so that there would be a peak of 18,000 kw., and the complete cycle of no load to 18,000 kw. would occupy about 1½ minutes.

Mr. T. Ferguson (British Westinghouse Co.) said that the ideal arrangement would be to have a separate winding plant for lowering and raising men, but as a rule it would not be practicable. He had recently come across a proposition for installing a hoist for men in the up-cast or ventilation shaft. Of course, the cage had to be made so as to prevent obstruction to the ventilation. The eddy-current brake offered considerable safety and ease of manipulation. For example, if you had a tail or balance rope between the cages, and the torque thus became uniform throughout the wind, it was an easy matter to switch on the exciting current to the eddy-current brake and leave it on, and then simply operate the main control lever in a natural manner, starting the load downwards, if necessary, by a short application of current; then bringing the control lever back to the off position, when the load would descend at a uniform rate under the action of the eddy-current brake; then, finally, pulling the control lever backwards so as to apply counter-current, and thus bring the load to rest.

Mr. A. B. Mallinson (Mather & Platt, Ltd.) thought that colliery people would be apt to condemn large eddy-current brakes, as, for winding deep shafts, one of the first requirements was that you must return power to the line whenever possible. With large electric winders the losses between winds (due to the running flywheel set) would, he thought, be so reduced that D.C. winders with a flywheel converter would show an overall efficiency better than that of A.C. winder equipments.

Mr. A. F. Stevenson said that he had known of a case in which power was being returned to a power company's mains, and as they looked upon it as bad business they put a ratchet on the meter to prevent its going backward. The rheostatic method of control applied to a three-phase motor on the power supply mains appealed to him as the most suitable for colliery conditions; the checking and adjusting of the cage position being done by counter-current in exactly the same manner as steam is used at present.

Mr. W. Bolton Shaw asked what happened when the main switch of a three-phase motor running at normal speed was rapidly switched over to the reverse position. He had found in the case of a small haulage motor that the current rose to a high value even if full resistance were switched into the rotor circuit in the interval between opening the main switch and closing it on the reverse position. It seemed to him that unless energy were returned to the line, the only argument in favour of electric braking was that it would lend itself to lighter and more easily regulated control apparatus than the mechanical friction brake.

Dr. Rosenberg, in reply to Mr. Cramp's question as to the use of multiple pole induction motors, said that it would hardly be possible to get a smooth gradual braking over any big range in this way, but that the pole changing device could be used to get an economical running at half speed to lower men. An objection against this with direct-coupled motors was the great number of poles which would be required, and the deterioration in performance which such an arrangement gave, even at full speed. As to the suggestion to make a D.C. winding motor heavily compounded, and to use it for braking purposes as a series generator, the speed of the compound motor was dependent upon the load, and this would always be undesirable, but specially objectionable in cases when the torque changed during the trip itself, when, for instance, there was no balance rope, and the weight of the rope worked at first against and afterwards with the torque of the motor; in this case, violent speed variations would occur. Mr. Mallinson mentioned that the eddy-current brake did not allow of the power being returned to the line. For English coal mines, the eddy-current brake would hardly ever be required. In mines where coal- and men-winding is done at the same speed, and trips with unbalanced load are of rare occurrence, the expense of an eddy-current brake would not often be justified. The last speaker asked whether the rushes of current were not too great if the motor was reversed while running at full speed. This would not happen if the controller was properly designed for the service. For braking with counter-current, a larger resistance is required than for starting, and therefore liquid starters, if to be used for counter-current, have a special sluice gate which allows a lower water level for braking. A controller of an ordinary haulage motor with only a few steps, and which would allow on the first step for starting, say, twice normal current, would, if reversed with the motor running at full speed, give a rush equal to nearly four times the normal current.

THE PRETORIA PIT EXPLOSION

THE cause of the disastrous explosion which occurred on December 21st last in the Yard seam at the Pretoria Pit of the Hulton Collieries is as yet unknown, but various suggestions have been made, including one that the fire-damp and coal-dust was ignited by the sparking of an electric coal-cutter employed in the mine. Mr. J. Gerrard, H.M. Inspector of Mines, who has been leading the exploring party, has stated, however, that his investigations in that section of the Yard seam in which the coal-cutter was in use have convinced him that the explosion was not due to sparking of the motor, as he found the cable disconnected and wound on a reel some yards away from the machine. He points out also that the coal-cutter was worked at night only, whereas the explosion took place about 8 o'clock in the morning. There was also an electrically-driven jig conveyer at the coal face, which was being loaded, and was about three-quarters full at the time of the explosion, so that it would not have been running; Mr. Gerrard is, therefore, convinced that this did not cause the explosion either. Notwithstanding these facts, the miners are very distrustful of the electrical plant, and at a meeting on December 29th of some 600 men employed at the various pits of the Hulton Colliery Co., the miners agreed to start work on the following morning only on the understanding that the electric coal-cutters should not be worked. It was pointed out to them that the electric lighting at the bottom of the shaft and the electric haulage were absolutely necessary if the coal was to be got out, and the continuation of these was agreed upon. This arrangement only holds, of course, until the result of the investigations into the cause of the accident have been made known. Further details will, no doubt, be given at the inquiry, which it is expected will be held at Westhoughton on January 24th. Many statements were made at the inquest as to the presence of gas in the mine previous to the accident, and one miner mentioned that a man in charge of the conveyer had referred to the sparking of the motor.

THE CARE OF UNDERGROUND PLANT

A PAPER by Mr. R. R. Smith entitled "Inspection and Repair of Electrical Plant Underground" has been read and discussed at several of the recent branch meetings of the Association of Mining Electrical Engineers. In view of the rough usage to which colliery plant is subjected, the author emphasised the necessity for systematic inspection by a competent person, and outlined the system of inspection in use at his own colliery as follows:—

An assistant electrician goes down the pit at 6.30 a.m. and takes charge of a district covering roughly 180 statute acres, there being in this section some 30 motors, four sub-stations, six switch-rooms, cables, lights, telephones, and signals. It is his duty to visit each motor and sub-station, and to take the leakage indicator readings while the plant is running. He also tries the telephones and signals, and examines all cables, earth-wires, and lighting, any defects being noted. Should a fault occur which requires immediate attention, he sends to the surface for a man, stating the nature of the trouble, so that the correct tools may be brought down. If the defect is serious, the Inspector stands by until the second man has arrived, and then proceeds upon his rounds, it being his business to inspect, and not to repair. He notes the maximum load on each motor, and if this is excessive endeavours to ascertain the cause, and reports thereon. When the winding finishes, at 2.30 p.m., it is his duty to examine the interral parts of the switches of two of the motors, and to make any necessary adjustments. Two sets of switches are thus taken each day, which means that each switch is examined once every 14 days, and from experience this proves ample. Should the oil show signs of carbonisation, a sample is taken and tested, new oil being sent down if necessary. Every week a motor is opened out by men from the surface, cleaned, and the clearances taken. The Inspector works his way round to examine it, and if the motor is in good order it is put together again. Further, when any work is done below ground, the Inspector has to satisfy himself that it has been done in an efficient manner, he being held responsible to the engineer for passing it. Insulation tests are taken monthly as far as possible. A whole section is taken at once, and if this comes below a certain minimum resistance, then each individual part is tested until the fault is located. The tests are recorded in a book, it being stated which cables, switches, &c., are taken together, and if the insulation of any part is found to be low, a note to that effect is made. At the end of each shift the Inspector fills up a Report on the condition of the plant, under suitable classified headings.

The author then briefly scheduled out the various defects which should be looked for, making a few remarks and suggestions, and in conclusion gave the text of the standard sheet of "Instructions to Electricians" which is hung up in various parts of the mine. These provide for due information being given in the power house when work on H. T. circuits is to be done, and all men about to take charge of high-tension work must show written instructions signed by the chief electrician. Danger labels are also required to be attached to switch handles controlling circuits upon which work is being done.

In the discussion at the Newcastle Branch on December 3rd, several members, in reference to one of Mr. Smith's headings, emphasised the necessity for lock nuts or similar devices on switchgear, and Mr. Clothier remarked that even the magnetic hammering on alternating circuits was sometimes sufficient to loosen nuts on connections. Mr. Barker and some other speakers mentioned cases where the tripping of switches was caused by the presence of rats and mice. Dr. Thornton spoke of the instantaneous action of the Merz-Price protective gear, and had seen a cable short-circuited by being cut in two by a steel wedge with the slightest flash. Mr. Burrows questioned the value of insulation tests as indications that a cable was not likely to break down, and preferred a pressure test. He also suggested that the Association should prepare a pocket-book on the maintenance of plant. Some discussion as to the correct level of the oil in oil switches ensued, and several members testified to the value of the butterfly attachment on Messrs. Reyrolle's switch in preventing an arc forming above the oil. Mr. Simpson referred to transformer troubles due to loose cores, and Mr. Clothier advocated, instead of danger cards, the locking out of switches controlling circuits worked on, and the carrying of the key by the man at work. The phases of feeders should be short-circuited, and earthed before work was commenced.

The discussion before a meeting of the Scottish Branch at Glasgow, on December 17th, was opened by Mr. Thomson, who thought that it was out of the question to keep a man only for inspection purposes at a moderate-sized colliery. He thought that the oversmen were quite capable of reporting anything wrong. Mr. Scott (Edinburgh Collieries, Ltd.) thought that the Paper applied chiefly to larger collieries than those in Scotland, a point as to which several other speakers agreed, and Mr. Anslow thought that to carry out the procedure outlined in the Paper, a very large electrical and clerical staff would be required. Both the last speakers emphasised the necessity for proper cable slings. Mr. Anslow also mentioned the unsuitability of lead-covered cables in mines on account of corrosion by the acid water found. Mr. Atchley (Harland Engineering Co.) agreed in this, and raised the question of fuses of too large size, which he called one of the bugbears of an electrician's life. Mr. Anderson (Messrs. Anderson & Boyes) failed to see how an inspector working under Mr. Smith's conditions would be able to make a satisfactory examination of each motor. It was important that earth plates, as well as earth wires, should be examined.

Mr. Smith's Paper was also discussed at Cardiff last Saturday.

ELECTRICAL MINING PATENTS OF DECEMBER

Among the Patent Specifications published during the past month of interest to electrical mining engineers was one by J. G. Barclay and A. N. Barclay, of Kilmarnock (No. 20,183 of 1909), for an automatic device for preventing the overwinding of pit cages. The supply of power is shut off first, and the brake and reversing levers are then actuated in succession.

Specification No. 26,051 of 1909, by R. Rohde, of Berlin, relates to feeding and reversing gear for electrically driven rotary and percussion rock drills, and covers the combination of an automatic feed and return motion with an arrangement whereby the machine is stopped at the end of the return stroke only after the parts have been reset for another feed. A device is provided for reversing the feed into the return motion and the return into the feed motion by the use of springs put in compression alternately and acting on a reversing bar controlling the feed and return mechanism and the switch.

A combined oil and electric miners' lamp is described by J. R. Allott, E. A. Hailwood, and E. Dean in Specification No. 29,818 of 1909. The electric lamp is provided with a reflector for the examination of roofs, and should the oil lamp fail, the electric light will be available to enable the miner to reach a re-lighting station. The lamp accumulator is annular in form, and is provided with a central receptacle for the oil.

In Specification No. 3,013 of 1910, W. Winsborough, of Wigan, describes a system of protection for three-phase systems particularly adapted to mines. The neutral point of the generator is connected to earth through the coils of a very sensitive relay which closes the circuits of one or more relays which in turn close the circuits of tripping coils for opening the main circuit-breakers. If the generator neutral point is not available, an artificial neutral can be obtained by means of resistances connected across the lines. The slightest earth leakage will thus break the main circuit. The specification also describes an arrangement in which a leakage indicator is used for detecting the amount of leakage, and showing on which feeder it occurs.

J. Shaw, of Kirby Moorside, in Specification No. 14,927 of 1910, describes a gear for the prevention of overwinding of pit cages, which can be adapted to electrically driven engines, and a gear for the same purpose, but more particularly for steam winders, is described by J. W. Melling, of Wigan, in Specification No. 13,152 of 1910.

Home Office Prosecution.—At Linlithgow Sheriff Court on November 29th, Mr. Scott Lees, manager of the Dalmeny mine, South Queensferry, of the Dalmeny Oil Co., was fined £2 as the result of a prosecution by the Home Office under the Special Rules for having failed to maintain an electric motor and switchgear in a safe condition in June last. For the defence it was stated that the defects were caused by a sudden creep of the strata.

Cumberland Branch, Association of Mining Electrical Engineers.—This Branch held its first annual dinner at the Grand Hotel, Whitehaven, on Saturday, December 17th, 1910. There was a very good attendance of mining, mechanical, and electrical engineers, and the Institutions of Mining, Mechanical, and Electrical Engineers, and other societies were represented. The dinner was followed by a musical programme, in which Messrs. Rayles, Humphreys, and J. Glynn Williams took part, and several humorous recitations by Mr. W. Leck, H.M. Inspector of Mines for the district, were greatly appreciated. The local president, Mr. T. P. Martin, in a few remarks, expressed the regret that Mr. W. Maurice (the president) was unable to attend, and Mr. B. Sankey, A.M.I.E.E., Borough Electrical Engineer of Whitehaven, in responding to the toast of "Kindred Associations," expressed his interest in the Association. Mr. Cecil Walton, president of the Cumberland Scientific Association, very generously offered to allow the branch to make the Scientific Institute their headquarters, with use of the library, the lecture hall, and lantern. The offer was accepted with enthusiasm.

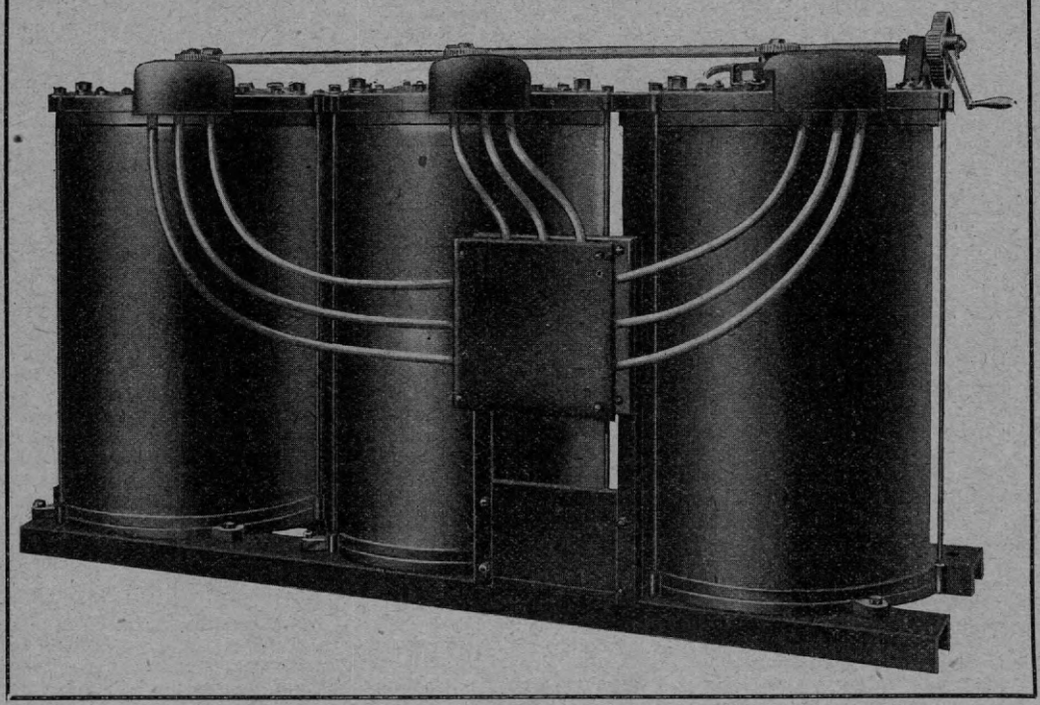
Hosted by Google

Articles of Interest to Mining Electrical Engineers published in "Electrical Engineering" during December.

Dec. 1st.—Monthly supplement on ELECTRICAL ENGINEERING IN MINES, opening with an illustrated description of the electrical equipment of the Leven Colliery, Fife, which includes mixed-pressure turbine plant. An official report on electricity in mines in 1909 is reproduced, and accounts are given of various meetings where electrical mining matters have been discussed. At one of these Mr. Clothier read a Paper on "Switchgear for Mines." Mr. S. Mavor also chose the power equipment of collieries as the subject of his address to the Glasgow Section of the Institution of Electrical Engineers; while Mr. J. G. Wilson opened a discussion on "Electric Winders," at the Newcastle Section. Some new motor controllers and a fire-damp safety cut-out are also described.

Dec. 8th.—Illustrated description of a Diesel engine plant. A note on a new boiler cleaning tool.

Dec. 15th.—Special literary supplement containing reviews of books on electrical engineering, &c., and a list of books recommended in all branches of the subject. An article on motor controllers. An account of an emergency installation of an electric motor.



Dec. 22nd.—Special articles on arc and incandescent exterior lighting by up-to-date methods.

Dec. 29th.—Illustrated description of the electrical equipment of a large manufacturing works. Report of a Paper describing the Merz-Price protective system, and the discussion thereon.

Whitehaven Disaster.—At the Home Office inquiry into the Whitehaven Pit disaster, which was concluded on December 2nd, the jury returned a verdict to the effect that the 134 men and boys were killed in an explosion of fire-damp, but that there was not sufficient evidence to show the source of ignition. Mr. J. H. Blackett, mining engineer, of Durham, called in as an expert witness by the Whitehaven Colliery Co., suggested that electric hand lamps would be safer than ordinary lamps under conditions such as existed in the part of the mine where the explosion took place. Mr. Richards suggested that some electric lamps should be tried for a period of six months, and Mr. Helder stated that the Colliery Co. were quite willing to make the trial. The jury added a recommendation that a strict observance of the rules should be required, but made no reference to the use of electric lamps.

CORRESPONDENCE

LAMP DIMMERS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—At the present time there is a big scheme of advertising on foot relating to a regulating switch for incandescent electric lamps. According to the circulars, the said regulating switch is something phenomenal, but on examination I find it is simply a neat design embodying the old and wasteful method of putting resistances in circuit with the lamps. The circular says: "You turn up your electric light and you turn it down just like gas," and a summary of advantages is set out. The advertisement includes a Faraday House certificate of a test on one of the switches, but this certificate carefully avoids all reference to the very heavy current consumption per candle-power due to the energy taken by the resistance. In the whole of the circular there is no reference to watts per candle-power, and I think, therefore, that the figures appearing hereunder, which are the result of tests made on one of these switches obtained out of stock from a contractor, will be interesting:—

Position of switch.	Total watts.	Lamp watts.	Resistance watts.	C.P.	Watts per c.p.	Total watts per c.p.
Full on	64	64	0	42	1·52	1·52
1st stop	52	34	18	9	3·77	5·77
2nd stop	44	21	23	2	10·5	22
3rd stop	38	15	23	·7*	21·4*	54*
4th stop	30	8	22	·2*	40 *	150*

*Approximate.

These figures were obtained with a metallic filament lamp, and if a carbon lamp had been used, the watts per candle-power would be much heavier.

I should not think of recommending a device which entails such a heavy and wasteful expenditure of energy per candle-power obtained. It would be far better and more economical to use two lamps, one of the candle-power required for ordinary illumination, and the other of small candle-power to be used as a night-light. In this way a consumer would get something like good value for his money. I believe lamp-makers can produce lamps with the two filaments in one bulb, and that such lamps are already in the market, this being a reasonably efficient and economical arrangement.

Borough of Harrogate, Yours faithfully,
Electrical Engineer's Offices, GEO. WILKINSON.
33 Swan Road, Harrogate.
December 30th, 1910.

[We quite agree with Mr. Wilkinson that resistance dimmers should not be used for the purposes of economy, but they are very convenient when the dimming of lamps is occasionally required without altering the wiring. Where, on the other hand, it is to be a regular practice, double filament lamps with 3-contact lamp-holders and 2-way switches should be employed; several lamp-makers supply such lamps, the holders are also obtainable, and 2-way switches with intermediate "off" position are a regular stock article. Double filament lamps with the switching arrangement on the lamps, although simpler, are more troublesome to use and are not so popular.—ED. E.E.]

ANSWERS TO CORRESPONDENTS

Correspondents must in all cases send their names and addresses with their queries, and, if they do not desire the reply to be published after their own name, should add a "nom de plume." Questions should be addressed to the Editor, ELECTRICAL ENGINEERING, *203–6 Temple Chambers, Temple Avenue, London, E.C. The Editor will not guarantee to answer all questions in this column, and the enclosure of a stamped and addressed envelope is therefore desirable. Books recommended will be forwarded on receipt of a remittance for the amount mentioned.*

J. A. HOPKINS.—We should recommend you to use 7/16 cable from the switchboard to a distributing board placed in one of the shops near the "covered yard," and from there to wire in circuits of five lamps, using 3/20 cable. The lamps in the shop containing the generating plant could be wired in three circuits (say with 3/22 cable) from the main switchboard. It will be best to have a charging board for the small accumulators, fitted with a regulating resistance, and wired as a separate circuit with 7/20 cable. You would find it more convenient to use 50 volts (using a 50 volt dynamo) as the pressure, instead of 75 volts, as 50 volt lamps are a regular stock size.

W. R. CASTLE.—A tape-cutting machine is practically no more than a lathe, and almost any machine tool maker could supply this. Johnson and Phillips make a speciality of cable-making machinery, and would also be able to supply tape-cutting machines.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

HOLOPHANE REFLECTORS.—A new leaflet from the Sun Electrical Co., Ltd. (118-120 Charing Cross Road, W.C.), lists the latest forms of Holophane Stiletto reflectors of the distributing, concentrating, and focussing types. The company have also placed on the market a new form of adjustable gallery, ensuring the correct relative positions of the lamp and the reflector.

INSTRUMENTS.—A new supplementary list from Siemens Brothers & Co., Ltd. (Caxton House, Westminster), deals with portable frequency indicators on the Frahm vibrating reed principle, and a special series of demonstration instruments for lecture room and school use. These represent the electromagnetic, moving coil, and induction types. The movement is visible in a glass case, and two scales are provided, one with a large open dial to face the students, and the other with a smaller, more accurately graduated dial to face the lecturer.

ADVERTISING SIGNS.—The Sun Electrical Co., Ltd. (118 and 120 Charing Cross Road), have issued a new edition of their electric illuminated sign catalogue. The list includes various examples of new designs using luminous raised opal letters, and the latest pattern of the company's mercury-contact type of flasher is described. (See ELECTRICAL ENGINEERING, Oct. 20th, page 662.)

ALUMINIUM.—A card from the British Aluminium Co., Ltd. (109 Queen Victoria Street, E.C.) gives tabulated particulars of aluminium sheet. On the reverse side is a view of the company's works at Kinlochleven.

STORAGE BATTERIES.—A pamphlet from the Hart Accumulator Co., Ltd. (Stratford), gives particulars of special 8-, 10-, and 12-volt batteries for motor-car and carriage lighting.

TELEPHONES AND BELLS.—The Sterling Telephone and Electric Co., Ltd. (200 Upper Thames Street, E.C.), have issued a revised edition of their "abridged" catalogue of telephones and electric bells, which, although "abridged," is a 76-page book. The principal revised portion relates to the "Primax" system of common battery intercommunication telephones, designed particularly to reduce induced cross-talk to a minimum. The same company have sent us a book containing diagrams showing various methods of connecting up their telephones. The diagrams are clear and practically executed, and every user of "Sterling" telephones should apply to the company for a copy of this book.

WATTMETERS.—A leaflet issued by the Allgemeine Elektricitäts Gesellschaft (Berlin) contains a brief illustrated description of the construction and use of the A.E.G. wattmeters on the dynamometer principle for A.C. and D.C. circuits.

CALENDARS, &c.—The Hart Accumulator Co., Ltd. (Marshgate Lane, Stratford, London), have taken the opportunity of the season in sending to their friends a neat and convenient desk blotter.

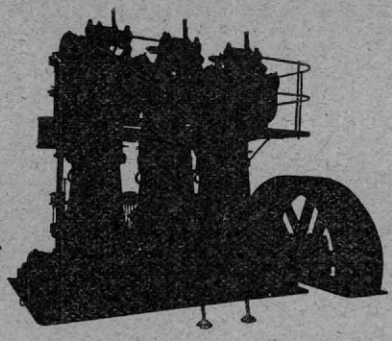
Messrs. Haslam & Schontheil, Ltd. (Western Mail Chambers, Cardiff), send us a scribbling block made up of squared paper with a few sheets interleaved, to call attention to some of the electrical material handled by them.

The combined calendar and blotter from Messrs. Alfred Graham & Co. (St. Andrews Works, Crofton Park, S.E.), who specialise in loud speaking telephones, is one of the most convenient that we have seen.

The British Thomson-Houston Co., Ltd., have prepared an attractive wall calendar with a large sheet for every month. This is illustrated with various B.T.-H. electrical installations in collieries, and should therefore be of particular interest to colliery owners, managers, and others in any official capacity connected with the mining industry, and a copy will be sent post free to any colliery upon application being made to the Publication Department, B.T.-H. Co., Ltd., Rugby. A particularly useful feature is the inclusion on each sheet of the next and last months in smaller figures.

The calendar of the Brush Electrical Engineering Co. is, as usual, an artistic production. It bears an effective coloured reproduction of an oil painting, and has a tear-off sheet for each day, containing particulars of historic anniversaries, &c.

Messrs. Charles H. Blume (Insulating Varnish Department, The White Building, Fitzalan Square, Sheffield) accompany their compliments with a neat monthly tear-off calendar.



The monthly tear-off calendar of the Western Electric Co., Ltd., distinguishes itself by its quiet and harmonious design and colouring, and the clear printing of the calendar itself.

Messrs. Venner & Co., anticipating a flourishing year for the electrical industry, are presenting a neat leather sovereign purse to their friends. They ask us to say that should any of their customers not have received one, they would be pleased to forward one on receipt of name and address. They are unable to distribute these to any who are not customers, as their stock is nearly exhausted.

A pocket diary of convenient size and shape, handsomely bound in morocco leather, is being sent to their friends by the Dussek Bitumen Co., Canal Bank, Deptford, S.E.

The pocket diary and engagement book which accompanies the good wishes of Messrs. Johnson and Phillips, Ltd., will appeal to those who appreciate a small and compact book.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published December 29th, 1910

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

3,013/10. **Protection of Three-phase Distribution Systems.** W. WINSBOROUGH (Wigan). This specification describes a method of protection for three-phase systems, in which the slightest leakage to earth causes the supply to be cut off. Further particulars are given under "Electrical Mining Patents of December," in the supplement to this issue.

7,463/10. **Prevention of Induced Currents in Shafts and Bearings.** FELTEN & GUILLEAUME LAHMEYERWERKE A.-G. In order to neutralise the E.M.F.'s induced in shafts and bearings by the fluxes which pass through these parts, a winding is arranged on the stator in such a way that an E.M.F. is induced in it by the influence of the same field fluctuations which produce the shaft voltage. The winding is short-circuited, and counteracts the field fluctuations which induce currents in the shaft. Five figures.

10,943/10 and 10,955/09. **Arc Lamps.** H. W. LAKE (*W. E. Clark, U.S.A.*). The first of these two specifications describes an enclosed vertical carbon lamp with very sensitive regulating mechanism to provide a steady light. The plunger controlling the position of the lower carbon is immersed in mercury in a cylinder, on which is wound a solenoid of a special construction to give an even pull over a long range. (Three figures.) The second specification describes an enclosed lamp, in which the upper carbon is suspended from a plunger working in a vertical solenoid. The latter is provided with a closed magnetic circuit formed by the casing of the lamp. Three figures.

15,014/10. **Repulsion Motor.** A. BIBER (Pforzheim, Germany). This specification describes a single-phase commutator repulsion motor in which two pairs of brushes are provided per pair of poles; one pair is used for running in one direction, and the other in the other. A starter with a starting resistance for each pair of brushes is provided. One figure.

17,415/10. **Prepayment Meter.** W. S. SPRAGUE and CHAMBERLAIN & HOOKHAM, LTD. In specification No. 3,250/10, was described a prepayment mechanism combined with an electricity meter in which a wheel is rotated in one direction on the insertion of a coin, and is permitted to rotate in the opposite direction by the working of an escapement worked by the meter. This specification describes a mechanism in which the necessity of a movable pawl is dispensed with, and the escapement is instead carried through part of its oscillation at a high speed. Two figures.

21,326/10. **Metal Filament Lamps.** BERGMANN ELEKTRICITÄTSWERKE A.-G. This specification describes a method of effecting simultaneously the sealing in of the leading-in wires and the fusion of the central glass pillar of the filament carrier to the foot of the lamp bulb. A special appliance for the purpose is also described. Nine figures.

23,044/10. **Guiding Ships.** C. ARNOLD (Mechlenburg, Germany). Ships are guided along the channels of river mouths and harbour entrances by means of instruments on deck which are actuated by magnetic induction from a cable laid along the proper course. Rapid current impulses are sent through the cable, and these affect two coils on the ship, placed at right-angles to each other, and connected to telephones. Morse signals can be transmitted to the ship by the same means. Three figures.

25,008/10. **Ignition Apparatus.** R. BOSCH. This specification relates to the construction of high-tension ignition coils, and describes a method of insulating the several sections of the secondary winding one from another.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables & Wires, Insulating Materials, &c.: CODD [Electric supply system] 29,329/09; ROGERS [Distribution system for mines, spirit stores, &c.] 4,066/10.

Dynamos, Motors, & Transformers: MILCH [Control of A.-C. motors] 20,743/09; STEVENS [Petrol-electric transmission system] 2,700/10; SCHLICK [Bicycle lamp dynamo] 12,524/10; SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens Schuckertwerke Ges.*) [Ward-Leonard control system] 22,110/10.

Electric Ignition: RUPPERT [Ignition of gas burners] 29,606/09; LONGFORD [Sparking plugs] 339/10; MIDGLEY and VANDERVELL [Ignition dynamo] 2,525/10; CHRISTMAS [Sparking plugs] 10,842/10; RAWSON [Ignition mechanism] 14,754/10; BOULT (*Ruzicka*) [Ignition mechanism] 18,946/10; CURTISS & HARVEY, LTD. and SMITH [Electric detonators for submarine blasting] 22,594/10; R. BOSCH [Current indicator] 23,049/10 and [Ignition apparatus] 24,687/10.

Electrometallurgy and Electrochemistry: JOHNSON (*Chemische Fabrik Griesheim Electron*) [Manufacture of alkali metals] 29,795/09; KOOPMAN [Electric welding of joints in metal structures] 30,097/09; PETERSSON [Charging resistance furnaces] 6,035/10; SMITH and DEAKIN [Apparatus for electrodeposition of metals] 7,225/10; PETERSSON [Resistance furnaces] 8,711/10; HENRI, HEILBRONNER and VON RECKLINGHAUSEN [Sterilising liquids] 14,128/10; THOMSON [Furnaces] 15,169/10.

Incandescent Lamps: RENNERT [Miners' lamps] 4,451/10; MADDEN and HOUSKEEPER [Manufacture of filaments] 7,331/10; WEBER [Mercury-carbon filament lamp] 9,250/10; KNIGHT [Manufacture of incandescent lamps] 24,810/10.

Instruments and Meters: MURRAY [Meters] 28,947/09; THOMAS WALKER & SON, LTD. and WALKER [Electrical ship's log apparatus] 29,448/09.

Storage Batteries: DOBBIE [Prevention of over-charge or over-discharge] 29,496/09; GATINAUD, 6,746/10.

Switchgear, Fuses, and Fittings: REASON MANUFACTURING CO. and REASON [Time switches] 30,051/09; ROGERS [Wiring system for mines, spirit stores, etc.] 4,066/10; ADAMS MANUFACTURING CO. (*Cutler Hammer Manufacturing Co., U.S.A.*) [Multiple switch motor-starters] 5,270/10.

Telephony and Telegraphy: BELCOURT and LEBRET [Bell signalling apparatus] 29,637/09; SIEMENS BROS. & CO. and IRELAND [Telephone installations] 29,677/09; SIEMENS BROS. & CO. and HIRD [Telephone switchboards] 8,551/10.

Traction: DE PROSZYNSKI [Operating tramway points from vehicles] 8,602/10; SIEMENS BROS. & CO. (*Siemens & Halske A. G.*) [Power operated signals and points] 10,037/10; GRESLEY [Tramway vehicles] 17,147/10; ENGEL [Trolleys or collectors] 17,380/10.

Miscellaneous: MACFARLANE [Ship's winches] 29,259/09, and [Centrifugal drying machines] 29,549/09; COCKAYNE [Smoke consumption] 29,627/09; SCOTT and MILLER [Disc coal-cutter] 4,357/10; WILLIAMS [Electrically-protected plates for safes] 11,550/10; THOMAS [Portable drills] 14,453/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Incandescent Lamps: SKAUPY [Manufacture of metal filament lamps] 15,621/10.

Storage Batteries: KAMPERDYK [Plates] 28,419/10.

Telephony: SIEMENS & HALSKE A.-G. [Telephone exchanges for automatic call distributors] 27,860/10.

Miscellaneous: CABOT [Electric conversion] 27,696/10; JULIUS PINTSCH A.-G. [Recording sound] 27,889/10; GILES [Electrical condensers] 28,179/10; VON PAUSINGER [Apparatus for indicating presence of inflammable gases] 28,697/10.

The following amended Specification can now be obtained.

BROOKS and ALSTON [Combined ignition coil and distributer] 15,802/09.

Opposition to Grant of Patents

16,300/09. **Prevention of Corrosion of Steel.** W. E. BULLOCK and J. CALCOTT (Coventry). Opposition has been entered to the grant of this patent, which covers a process for protecting iron and steel from rusting. It consists in subjecting the surface to be protected to the action of a boiling mixture containing phosphoric acid, while the surface acts as cathode to a current passed through the mixture.

23,014/09. **Arc Lamp.** J. NEU. Opposition has been entered to the grant of this patent. The specification, abstracted in ELECTRICAL ENGINEERING, November 10th, 1910, describes a lamp of the supported carbon type, with a pivoted stop, which tips up and cuts the lamp out of circuit when the carbons are fully consumed.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Dynamos, &c.: B. G. LAMME [Carbon-brush holder] 19,125/04; ALLMÄNNA SVENSKA ELEKTRISKA AKTIEBOLAGET [Control of single-phase compensated shunt motors] 10,304/05.

Switchgear, &c.: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Motor controller] 19,885/04; A. ROMAIN and J. AYGUESVIVES [Combined lampholder and cut-out] 20,007/04; G. HELPS [Lamp pendants] 18,535/05.

Traction: R. H. SIMPSON and W. PARK [Motor trucks] 19,714/04; SIEMENS BROS. & CO. (*Siemens & Halske A.-G.*) [Electro-pneumatic operation of signals and points] 18,402-2A/05.

Miscellaneous: D. M. NESBIT [Feedwater-heater] 21,020/97.

Hosted by Google

LOCAL NOTES

Airdrie: *The "Fair Fare" System.*—The Airdrie & Coatbridge Tramways Company announce their intention of abandoning the "fair fare" system of charging by means of farthing stages on their tramways.

Finchley: *Supply Outside Area.*—The Friern Barnet Council have agreed to the Finchley Council applying to the Board of Trade for an Order to supply electricity in their district.

Leicester: *Management of Electrical Undertaking.*—The Electricity Committee have decided to recommend the Council to adopt Mr. James Swinburne's suggestion that the two power stations should be worked as one undertaking, instead of two separate ones as at present. Mr. Swinburne estimates a saving of about £2,000 per annum if this course is adopted.

London: *Hammersmith: Tramways.*—A difference has arisen between the Council and the London United Tramways, Ltd., as to the condition of the tramway tracks, and the Council have applied to the Board of Trade for the appointment of an arbitrator. The Council state that the track rails are in a defective and dangerous condition, and that the only effective and satisfactory way of dealing with the matter is to reconstruct the whole of the tracks in respect of which the complaints are made.

Malton: *Street Lighting.*—The directors of the Northern Counties Electricity Supply Co. have offered to accept £275 for the street lighting posts and fittings, provided the agreement for the supply of energy for street lighting is renewed for a further term of three years. Although willing to pay this sum, the Council have decided not to renew the agreement, but to invite tenders for street lighting from the Gas Co. and the Electricity Co.

Russia: *Electric Railways.*—According to an American Consular report the Moscow-Windau-Rybinsk Railway has purchased an accumulator railway car for experimental purposes. The car has cost about £7,700, and is designed for speeds up to 67 miles per hour. It is intended to run the car on the line between St. Petersburg and Tsarskoye-Selo.

South Africa: *Tramcars.*—The Durban Corporation have instructed the Tramways Manager to proceed with the construction, in the Corporation's car-sheds, of five new tramcars.

Stafford: *Wiring Regulations.*—The Electrical Engineer has been instructed to prepare regulations which all wiring contractors in the town will be required to comply with. The Engineer has also been instructed to report upon the charges for power supply, the supply of electricity at cost price, and the supply of electricity for power purposes with time switches. The whole question of charges is to be considered at a special meeting of the Electricity Committee shortly.

Tottenham: *Overhead Telegraph Wires.*—Another difference has arisen between the Council and the Postmaster-General with regard to the erection of overhead telegraph wires, and proceedings are to be taken in the County Court in order to test the matter. In a similar dispute a short time ago the Council were successful in forcing the Postmaster-General to put the wires underground.

Uruguay: *Electric Traction.*—A scheme is under consideration for the construction of an electric railway from Monte Video to Colonia. The distance is 110 miles, and at Colonia it is anticipated that the trains will be carried on ferry boats thirty-four miles to the port of Buenos Aires, and thence travel underground to the centre of that city. It is proposed to erect a power station and utilise the waters of the river Santa Lucia. The project has been approved by the Lower Chamber, and no serious difficulties are anticipated from an engineering point of view.

Worcester: *Municipal Wiring Powers.*—In consequence of the recent decision of the Council not to allow the Electricity Committee to develop their undertaking by making arrangements for the wiring of premises and the hiring of apparatus, Mr. A. H. Parker, Chairman of the Electricity Committee, has resigned. The Committee have informed the Council that they find a difficulty in obtaining the services of a Chairman, as the decision referred to has given the impression that the Council are not prepared to give such assistance to the Committee as they must have if they are to manage successfully such an important undertaking.

Ystradgynlais: *Electric Lighting.*—The Glantawe Electric Light Co. have completed their installation, and public lighting was switched on for the first time on Christmas Eve.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Burnley.—The Electricity Committee have under consideration the question of extending their generating plant.

Canada.—The incorporation is announced of the Central Canada Power Co. with a capital of about £2,050,000. The headquarters are in Toronto.

East Ham.—An inquiry was held last week concerning a loan of £17,420 for electrical extensions. There was no opposition.

London: *Hammersmith.*—The Electricity Committee recommend the installation of two new boilers with economisers, air-heaters, mechanical stokers, feed-pumps, steam pipes, &c., and a new steel chimney, at an estimated cost of £8,000; a 3,000-kw. turbo-alternator, with condenser, air-pumps, and accessories, £10,000; mains extensions, £3,553; services, meters, &c., £2,700; static transformers, £1,000; making a total of £25,253. In order to avoid sub-contracting as far as possible, the work is to be divided into nine specifications.

Plymouth.—Mains extensions are to be carried out in Exeter Street, St. John's Road, and Alma Street at an estimated cost of £68.

South Africa.—The Durban Corporation have sanctioned the expenditure of a further £30,000 for extensions to the power station. Mr. Roberts, the Borough Electrical Engineer, in his annual report, states that applications have been received for some 2,000 h.p., which at present he is unable to meet.

Turkey.—According to the *Board of Trade Journal*, H.M. Consul-General at Constantinople reports that the Turkish Ministry of Public Works invite tenders for the construction and working of electric tramways, and the supply of electricity in Adana. Tenders to Monsieur le Ministre du Commerce et des Travaux Publics, by March 14th.

Warrington.—Tenders for extra high-tension cable are invited by January 10th. Particulars from the Electrical Engineer.

Eleven Corporations have applied to the Board of Trade for extensions of their electric lighting areas or new Orders, and fifteen Companies have made similar applications in respect of Orders in different parts of the country. A complete list, with names of the promoters, can be obtained from Messrs. Wyman & Sons, Fetter Lane, London, E.C., at a nominal price.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

GREATER LONDON.

Proposed extensions at University College, Gower Street.

Estimates are to be prepared for lighting the St. George's (Mile End) Guardians' premises by electricity.

New Drill Hall in Willesden. Middlesex Territorial Association.

New branch Post Office at Poplar. H.M. Office of Works.

PROVINCES.

Cardiff.—Block of office buildings in James Street, Bute Docks. Architect, H. Budgen, 95 St. Mary Street.

Carlisle.—The School Management Committee of the Education Committee recommend that the Lowther Street School be fitted for electric lighting at an estimated cost of £75 12s.

Darlington.—Reconstruction of premises for the Darlington and Stockton Times Newspaper Co. Architects, Messrs. Hoskins & Brown, Court Chambers, Darlington.

Doncaster.—New Institute for the Trades and Friendly Society Institute, Ltd. Architect, F. Masters, Bank Chambers, Scot Lane, Doncaster.

Dublin.—Tenders are invited for the electric lighting of the Richmond District Asylum. Current is to be supplied by the Dublin Corporation. Consulting Engineer, Mr. T. Tomlinson, 16, Beresford Place, Dublin. Tenders are invited for the electric wiring of St. Peter's Church. Architects, Ashlin & Coleman, 7 Dawson Street, Dublin.

Dunfermline.—Institute in Nethertown Broad Street.—Also Women's Institute in Bath Street.

Glasgow.—Reconstruction and enlargement of Royal Institute of Fine Arts, Sauchiehall Street.

Gorleston.—New buildings for East Anglian Institution for Blind and Deaf Children. Architect, J. E. Burton, 57 London Street, Norwich.

Hosted by Google

Llandudno.—New church. Ecclesiastical Commissioners.
Swansea.—Additions to baths and laundry, St. Helens Road. —Eight houses, Jersey Terrace. Mr. J. Thomas.—Eight houses, Carmarthen Road. Mr. J. Pye.—Eight houses, Neath Road. Mr. H. Smith.—Six houses, Beechwood Road. Mr. R. Lacy.—Seven houses, Glanmor Road. Point Bros.—Seven houses, Barclay Terrace. Mr. J. Lewis.
Wishaw.—Proposed Town Hall.
Wolverhampton.—Extensions to premises of Patent Hydro Bread Co., Ltd., St. Mark's Street.

MISCELLANEOUS

Birmingham.—Tenders are invited by January 30th for the supply of stores during the year ending March 31st, 1912, including electrical sundries.
Blackpool.—The Corporation have decided to proceed with the scheme for providing 100 electrically controlled public clocks.
Bootle.—The Corporation invite tenders by January 18th for the supply and erection of two electrically-driven turbine pumps for the Raleigh Street pumping station. Tenders by January 18th. Particulars from the Borough Electrical Engineer.
Manchester.—The Corporation invite tenders for the supply of tramway rail bonds. Particulars from the Manager, and tenders by January 17th.
Plymouth.—The Electricity Committee will shortly be inviting tenders for the supply of meters for the ensuing 12 months.
Spain.—The Sociedad Anónima El Tibidabo have, says the *Board of Trade Journal*, applied for a concession to construct and work electric railways in Barcelona.

TENDERS RECEIVED AND ACCEPTED

Aberdeen.—The tender of Messrs. Stewarts & Lloyds, Ltd., of Glasgow, has been accepted for the annual supply of wrought-iron tubes and fittings to the Electricity Department.
London.—Messrs. Thomas Tilling, Ltd., have placed an order with Messrs. W. A. Stevens, Ltd., of Maidstone, for several additional petrol electric omnibuses for use in London. The chassis, with the exception of the electrical equipments, have been designed by, and will be manufactured by, Messrs. Thomas Tilling, Ltd., to whom Messrs. W. A. Stevens are supplying the electrical equipments. The first instalment of seven buses is expected to be running in May.

The Imperial Lamp Works.—An interesting "break-up" for the Christmas holidays took place at the Imperial Lamp Works, Brimsdown, on Friday, December 23rd. To every female employee, to the number of about 500, was presented a gold and enamel brooch and a fancy box of Christmas cakes, and to every male employee, cigars, tobacco, or cigarettes. The presentations were made in the girls' dining hall, which was tastefully decorated and ornamented with Christmas trees, &c. At the end of the proceedings mutual good wishes were exchanged and hearty cheers for the management given. We are glad to see that, at the Imperial Lamp Works (the output of which we understand has been increasing by rapid strides since the works were opened), the relations existing between the employers and employees are of so cordial a description.

The Association of Mining Electrical Engineers.—The first volume of Proceedings will be issued in January. It contains 300 pages, and includes Papers (with the discussions) on:—Accidents from Electric Shock; Electric Breakdowns in Collieries; Cables for Colliery Work; Relative Merits of D.C. and A.C. for Colliery Work; Discussion on Home Office Rules; Earthing as applied to Mining; Earthing Neutral Point of a Three-phase System; Mining Switch Gear; Flame Proof Apparatus; Storage Batteries in Colliery Work; The Cascade Three-phase Motor. Included in the Appendices are the Articles of Association, and a full list of names and addresses of the 700 odd members. The volume will be issued free to all those who had joined the Association by December 31st, 1910. To non-members the price will be 6s., but only a limited number of copies are available.

Telegraph Traffic.—The Direct Spanish Telegraph Co.'s Falmouth-Bilbao cable failed on the 21st ult., but was again working on the 31st.—The Bagdad-Bassorah line was down from the 23rd to 27th Dec.—The Compagnie Française des Cables Télégraphiques has had considerable trouble in the West Indies.—The Cape Hayti-Puerto Plata cable gave out first, and was followed by the section between Paramaribo and Cayenne, and on Christmas Eve the Fort-de-France (Martinique) Paramaribo cable also broke down. Telegrams for the latter place are being routed *viâ* Hayti.—On 30th Dec. the Djedda-Souakim cable broke down.—The Commercial Cable Co. has also had trouble with one of their sections.

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £58 15s. to £59 per ton (last week, £59 to £59 5s.).

"Pixielite" Strip.—We understand from the General Electric Co. that their well-known "Pixielite" strip system of decorative lighting has been officially approved by the London County Council as being in accordance with their suggestions for Coronation illumination. Large quantities are being manufactured in view of the enormous demand that is likely to arise. For a description of the system, which uses ordinary B.C. lamps, see ELECTRICAL ENGINEERING, September 10th, 1908, page 401.

Bankruptcies.—An application for the discharge of J. F. Davie, electrician, late of 10 Great Castle Street, Oxford Street, London, will be heard on January 18th, at 11 a.m., at Bankruptcy Buildings, Carey Street, London, W.C.
A. Yearsley, of 27 Brazenose Street, Manchester, has been appointed trustee for C. H. Pearson (Pearson & Co., electrical and sanitary engineer, 51A Mosley Street, Manchester). The public examination will be held at the Court House, Quay Street, Manchester, on January 20th, at 10 a.m.
The discharge of H. Barham, Electrical Engineer, 60 Fratton Road, Portsmouth, has been suspended for two years from October 18th, 1910.

Dissolution of Partnership.—W. J. Charles and A. Watson, Electrical Engineers, Edward Street, The Parade, Birmingham, have dissolved partnership.

Liquidations.—A meeting of the Chichester & District Electric Supply Company, Ltd., will be held at Electrical Federation Offices, Kingsway, London, on Jan. 13th, at 10.30 a.m., to hear the liquidator's account of the winding-up. This is not the company at present supplying electricity in Chichester.
The North British Electric Power Syndicate is to be wound up voluntarily. Mr. A. Wood, of Messrs. Monkhouse, Stoneham & Co., Salisbury House, London, E.C., is liquidator.
Mr. J. H. Bailey, 2 Booth Street, Manchester, has been appointed receiver and manager of the Small Power Dynamo Motor Co.
The British Electrical Device Co., Ltd., is to be wound up voluntarily. Mr. P. J. Boucher (72 Victoria Street, Westminster), has been appointed liquidator.

Siemens Telephones.—Messrs. Siemens Bros. Dynamo Works, Ltd., Tyssen Street, Dalston, London, inform us that they are installing an additional telephone line to cope with the enormous number of calls which they are continually receiving. Arrangements are also in hand for a still further increase in the number of the Dalston lines. The present telephone numbers are Central 8388 and 8389, and Dalston 4. The firm apologise to the many customers who have been seriously inconvenienced during the past few weeks, as many complaints have been received concerning the difficulty in getting through.

Awards at the Argentine Centennial Exhibition.—In connection with the Railway & Land Transport Section of the Argentine Centennial Exhibition last year, 920 awards were made. Great Britain secured a total of 222, made up of 82 Grand Prix, 12 Diplomas de Honor, 75 Gold Medals, 39 Silver Medals, 12 Bronze Medals, and 2 Hon. Mention.

Change of Address.—The Indestructible Cable Co. have removed their office to 20 High Holborn, London, W.C.
Mr. H. Boot has removed his London office from 4 Great George Street, Westminster, to Westminster Chambers, 7 Victoria Street, London, S.W.

Johnson & Phillips' New Offices.—Messrs. Johnson & Phillips, Ltd., have opened the following branch offices, showrooms, and stores:—Birmingham: 187 Corporation Street; Cardiff: 12 Castle Arcade; Dublin: 27 Anne Street, South; Glasgow: 159 West George Street: Leeds: 21 Bridge End; Manchester: 251 Deansgate; Newcastle-on-Tyne, 44B Blackett Street.

OSRAM·LAMPS

APPOINTMENTS AND PERSONAL NOTES

Mr. T. H. Roberts-Wray, who has been with Messrs. Crompton & Co., Ltd., as chief representative for eight or nine years, has started on his own account as consulting and inspecting engineer at 15 Leadenhall Street, London, E.C. Mr. Wray has had a large and varied experience in marine and general engineering work, and particularly in regard to the requirements of the British Admiralty and other foreign Governments.

The Chairman of the Union Cable Co., Ltd., thanks applicants for the post of cable engineer and works manager at the company's new works at Dagenham, and asks us to intimate that the position has now been filled.

We understand that Sir William Preece, K.C.B., is leaving England on January 14th for South Africa.

Mr. J. E. Mallinson, of Blackpool, has been appointed Chief Engineer to the Burmah Electric Lighting & Tramway Co.

Mr. Duncan Maclellan, of Messrs. Kelvin & James White, Ltd., has been appointed Borough Electrical Engineer at Oban. There were 171 applicants.

Mr. P. J. Pringle (late tramways manager, Burton-on-Trent) has arrived in Melbourne to take up his appointment as General Manager and Engineer of the Electric Supply Co. of Victoria, Ltd. His duties will include management of the electricity and tramway undertakings of Ballarat and Bendigo, and he will also act as Consulting Engineer to the electrical undertaking at Koolgardie, Western Australia. Mr. Pringle will reside at Ballarat, a city some 1,500 ft. above the sea-level.

A working mechanical engineer is wanted for small electrical power plant. (See an advertisement on another page.)

Mr. W. S. Wilson has resigned his position as Outside Manager of the Electrical Department of Messrs. Clarke, Chapman & Co., Ltd., to take up the position of Branch Manager with Messrs. Pinchin & Johnson, Ltd., at 44B Blackett Street, Newcastle-on-Tyne. Telephone No. Central 1691.

The Aston Electricity Committee recommend an increase in the salary of Mr. R. Foster, the Electrical Engineer, from £500 to £600 per annum.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

British Power Co.—The report for the year to January 30th states that the utmost endeavours have been made to place upon a more satisfactory footing for realisation the remaining undeveloped assets of the company. It is expected that shares will shortly be issued in the new Fife Tramway, Light and Power Company in exchange for the company's holding in the old Fife Electric Power Company. The company is also assisting in the finance of the Llanelly and District Electric Lighting Company, and hope to be able shortly to announce the completion of arrangements for considerably strengthening the financial position of the Nottinghamshire and Derbyshire Tramways, and the Derbyshire and Nottinghamshire Power Company. On the other hand, the Board have had to agree to accept ordinary shares at a greatly reduced value in place of their present holding of deferred shares in the Cleveland and Durham Electric Power Company. Of the remaining assets of the company there seems to be a slightly improved prospect for British electrical enterprises.

Rio de Janeiro Tramway, Light & Power Co.—A dividend of 1¼ per cent. on the ordinary stock.

Chloride Electrical Storage Co.—Interim dividend at the rate of 6 per cent. per annum upon the preference shares.

Aron Electricity Meter Co.—At an extraordinary general meeting on Friday, a resolution was passed, increasing the capital to £350,000 by the creation of 100,000 ordinary shares of £1 each.

Cleveland and Durham Electric Power.—An Order has been made confirming the reduction of the capital of this company from £1,000,000 to £700,000.

Tantalum Lamps for Railway Station Lighting.—Messrs. Siemens Brothers Dynamo Works, Ltd. (Tyssen Street, Dalston) have sent us an illustration showing a station of the Metropolitan Railway, which has now been lighted for some time by Tantalum lamps. The strength of the filament renders them particularly suitable for this class of work, where there is naturally a good deal of vibration. We understand that several other stations are to be similarly equipped.

SUMMARY

A communicated article deals with the subject of rotary converters. Their general features and uses are considered, and suitable transformer connections and switchgear are discussed. (Page 13.)

Particulars are given of the new submarine telegraph cable between England and Norway. This cable is the joint property of the British and Norwegian Governments, but is at present being worked by the Great Northern Telegraph Co. The new cable is single-core, with a conductor weighing 200 lb. per naut, and gutta percha, 200 lb. per naut. (Page 14.)

Our monthly article on new electrical supplies and accessories contains illustrated descriptions of some new switchgear, including a cheap line of small knife switches, a simple battery cut-out, a solenoid starter, a push-button switch, and a new quick make and break oil switch. Notes are also given on a convenient gallery for holophane shades, some new reflectors, an ingenious candle fitting, and a series of switchboard and portable instruments. In the section on heating and cooking apparatus a particularly cheap radiator and a new form of the well-known "Quartzlite" heater for use with a number of different utensils, are described and illustrated. (Page 15.)

A new zinc-carbon primary cell, with caustic soda excitant and a patented depolariser, has been introduced. The E.M.F. on open circuit is 2·7 volts, and the internal resistance 0·15 ohm. (Page 17.)

A 2,000-h.p. single-phase locomotive, constructed for the Loetschberg Tunnel Railway, has two commutator motors of the compensated series type, developing each 1,000 h.p. continuously at a speed of 26 m.p.hr. The trolley line pressure is 15,000 volts, and the frequency 15 cycles. (Page 18.)

Messrs. K. Faye-Hansen and G. Harlow dealt with the Merz-Price protective system in a Paper read recently before the Manchester Local Section of the Institution of Electrical Engineers. They considered that the Merz-Price system had great advantages in its power of instant isolation of faulty sections of a circuit, and favoured the balanced-current modification thereof. They further described another system of feeder protection specially immune from trouble due to capacity currents in the pilot wires. (Page 19.)

Under "Wiring Contractors' Point of View" we deal with the Australian Fire Underwriters' Association comments upon the quantity of cheap grades of wire and cable which is being imported into Australia. Attention is also called to an attempt in 1903 to settle the difference between the wiring contractors and municipalities. At Islington and Worcester there is friction between the Electricity Committees and the Corporations upon the question of municipal wiring powers. The majority of the Islington Lighting Committee are resigning. (Page 21.)

We give an illustration of an improved method of filament support for tungsten lamps. (Page 22.)

A letter from the Electrical Standardising, Testing and Training Institution refutes some aspersions cast upon a recent Faraday House Report. (Page 22.)

The Lepel patent for a wireless oscillation generator comprising metal discs separated by rings of paper, has been granted in Germany, in spite of the opposition of the Telefunken Company, whose patent for a similar device has been refused. This decision may have very far-reaching effects, in Germany and elsewhere. (Page 22.)

Among the specifications published by the Patent Office on Thursday was one by E. T. Ruthven-Murray describing various forms of limit-indicators, combined with a scale of charges on the fixed price per quarter principle. The consumer can increase (but not decrease) his limit, and in doing so causes the instrument to indicate a correspondingly higher charge.—W. A. Stevens describes a two-motor drive with chain-gear suitable for petrol-electric vehicles.—An improved method of Ward-Leonard control, in which the field

Hosted by Google

of the main motor is strengthened automatically according to the load, is protected by Siemens Bros. Dynamo Works. (Page 23.)

THE Sydney Electrical Engineer has prepared a scheme for displacing gas by electricity for street lighting.—The Brighton and Worthing Corporations have decided to oppose both schemes for tramways and trolley omnibuses between Brighton and Worthing.—The Stone system of train electric lighting is being adopted by the Canadian Pacific Railway Co.—An attempt is being made to prevent competition between the Manchester Electricity and Gas Departments.—The Elective Auditors point out that insufficient provision is being made for tramways renewals by the Wigan Corporation.—The Leicester Corporation have adopted Mr. James Swinburne's recommendations to link up the two power stations by means of motor generators, and to use one as a spare. (Page 24.)

A 1,000 kw. generating set is to be installed at Burnley; steam turbine plant at Halifax; motor generator at Cheltenham; generating set at Kendal; and economisers, superheaters, and mains at Peterborough. The £100,000 extension scheme at Hull is to be proceeded with. The Australian Postmaster-General's Department requires quantities of telegraph material; the Klerksdorp (S.A.) Council propose to instal electric lighting; and stores are required at Bexley, Battersea, and Islington. (Page 24.)

Telegraph Traffic and Movements of Cable Ships.—The cables of the Compagnie Française des Cables Télégraphiques in the West Indies have been giving trouble. The Fort de France (Martinique)—Paramaribo (Dutch Guiana) section, which was repaired on the 4th inst., again broke down on the 7th inst. Probably the c.s. *Pouyer Quertier* may have left already to repair other breaks, which will mean some delay in putting this section into working order.—Communication between Rome and Constantinople was down for a short while on the 7th inst.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JANUARY 12TH.

Institution of Electrical Engineers.

8 p.m. At Victoria Embankment. "Submarine Cables for Long Distance Telephone Circuits," by Major W. A. J. O'Meara. Adjourned discussion.

Institution of Electrical Engineers: Dublin Section.

8 p.m. At Royal College of Science.

Junior Institution of Engineers.

7.30 p.m. At Royal United Service Institution, Whitehall. "Depreciation of Buildings and Machinery," by H. F. Donaldson, C.B.

FRIDAY, JANUARY 13TH.

Electro Harmonic Society.

8 p.m. Smoking Concert, at Holborn Restaurant.

SATURDAY, JANUARY 14TH.

Birmingham and District Electric Club.

7 p.m. At Colonnade Hotel, New Street. Presidential Address by F. W. Foster.

MONDAY, JANUARY 16TH.

Junior Institution of Engineers.

7.30 p.m. At Caxton Hall, Westminster. Fifth lecture on "Law Relating to Engineering," by L. W. J. Costello.

Illuminating Engineering Society.

8 p.m. At Royal Society of Arts. Discussion on Library Lighting.

TUESDAY, JANUARY 17TH.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. At University. "Electric Heating as Applied to Cooking Apparatus," by Harold Gray.

Association of Mining Electrical Engineers.

8 p.m. At 39 Victoria Street, London. "Electricity in New South Wales Collieries," by E. Kilburn Scott.

WEDNESDAY, JANUARY 18TH.

Institution of Electrical Engineers: Birmingham Section.

7 for 7.30 p.m. Annual dinner, at Grand Hotel.

Institution of Electrical Engineers: Students' Section.

7.30 p.m. At Victoria Embankment. "Wireless Telegraphy, with Special Reference to Short Spark Methods," by P. R. Coursey.

THURSDAY, JANUARY 19TH.

Rugby Engineering Society.

8 p.m. At Benn Buildings, High Street. "Electric Power in Collieries," by J. Miller.

FOREMAN: What's this 'ere? I *arst* you to git "C.M.A. cable"; *he* won't 'ave no other. This ain't got no bloomin' buff All-British label!!

BRIGHT YOUTH: I does my best. I made quite sure by askin' Bill, and 'e ses them letters means Cable Made Abroad. They told me at the shop that this was best Anglo-Dutch.

Hosted by Google

NOTES ON THE ROTARY CONVERTER

(Communicated)

THE rotary converter may be said to be essentially a continuous-current generator provided with a certain number of slip rings, in addition to the commutator, connected to suitable points in the armature winding. The machine, if driven by mechanical power, would deliver both alternating current and direct current; if supplied with alternating current it will run as a synchronous A.-C. motor, and if supplied with direct current will follow the laws which govern the operation of a D.-C. motor, the machine working under the latter conditions being known as an "inverted rotary." It is intended to deal here chiefly with the machine as used to convert alternating current to direct current, as this is the condition chiefly met with in present-day work. Large rotaries are more satisfactorily built to run on a supply frequency of 25 cycles, but smaller machines are satisfactorily built for frequencies up to 50 and 60 cycles.

The alternating current in the armature of a rotary converter flows at such a time as to be partially neutralised by the current generated, which is afterwards commuted into direct current. Thus for a given output a rotary converter has a smaller armature than either a direct-current generator or motor, since the heating which is occasioned by the current is diminished on account of this neutralisation of the two currents. By increasing the number of slip rings in the machine, *i.e.*, also the number of tappings off the armature, it is found that this heating becomes less.

The following figures show the relative outputs of a rotary converter armature as compared with an armature of the same size of a direct-current generator, considered from the heating aspect :—

Direct Current Generator	100
Two-phase Rotary Converter	162
Three-phase Rotary Converter	133
Six-phase Rotary Converter	193

VOLTAGE AND CURRENT RATIOS.

The voltage ratios of the rotary converter depend on and vary with the nature of the A.-C. supply, whether single, two, or three phase, &c.; the shape of E.M.F. wave supplied; the number of armature conductors embraced by the poles; and whether the machine is used to convert from A.-C. to D.-C., or *vice versa*.

The following table of voltages is given for a rotary converting A.-C. to D.-C., with a sine wave, and poles covering approximately 75 per cent. of the armature circumference. The figures given are values at no load, and the resistance drop of the machines has been neglected :—

Direct Current Generator	100
Two-phase Rotary Converter	71
Three-phase Rotary Converter	61
Six-phase Star or Delta connected Rotary Converter	35·5

On full load, the drop in the machine will increase the ratio of A.-C. to D.-C. voltage by about 1·5 per cent. Varying the excitation of a rotary converter does not sensibly vary the ratio of A.-C. voltage to D.-C. voltage. Over-excitation, however, causes the supply current to lead, and under-excitation to lag, with reference to the impressed E.M.F. It therefore becomes necessary, when a varying D.-C. voltage is required, to resort to either hand A.-C. voltage regulation by means of an induction regulator, or to an automatic method by the use of choking coils and a compound D.-C. winding on the machine field, the latter method being the one usually adopted in practice. An over-compounding effect of from 10 per cent. to 15 per cent. may be obtained by this method.

The ratios of continuous current to alternating current for various forms of converter, all for unity power factor, and a sine wave, are given in the following table, the losses in the machines being neglected :—

Direct Current Generator	100
Two-phase Rotary Converter	71
Three-phase Rotary Converter	94·5
Six-phase Rotary Converter Star or Delta Connected	47·2

From these figures the following useful practical rules may be deduced for obtaining the approximate full load currents of the machines :—Two-phase alternating line current should be equal to three-fourths of the direct-current output in amperes. Three-phase A.-C. should be the same as the D.-C. Six-phase A.-C. should be equal to one-half the D.-C.

Those desiring to pursue these parts of the subject further will find an extended treatment of such matters in Hay's "Alternating Currents," Chapter XV.

TRANSFORMER CONNECTIONS.

As the voltage ratio is fixed by the nature of the machine, it is practically always necessary to employ transformers in conjunction with rotary converters. The connections shown in Fig. 1 are those mostly in use. For large machines, that shown as No. 4 has the advantage that only one secondary transformer is necessary, which simplifies the switchgear. Delta connections are to be preferred to star, as in the event

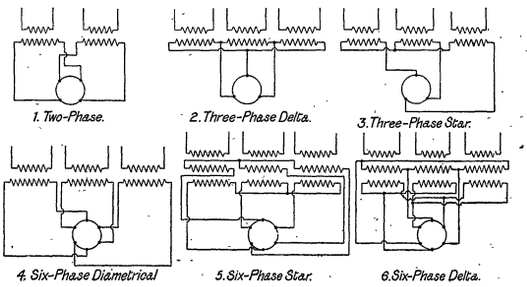

FIG. 1.—DIFFERENT METHODS OF CONNECTING TRANSFORMERS TO ROTARY CONVERTERS.

of one phase becoming faulty, two whole phases are still left in use for supplying the machine. Conditions, however, are sometimes met with in which a star-connected transformer is more suitable on account of the higher value of the secondary phase voltage.

STARTING ROTARY CONVERTERS.

The following methods are usually adopted for the starting of such machines :—A small induction motor mounted on the same shaft; starting from A.-C. side by means of tappings on the main transformer; or from D.-C. side as a D.-C. motor.

The first method is usually employed for large machines, where a heavy alternating line current would be drawn from the supply if the second method were employed. Starting is usually effected from the A.-C. side for machines of medium capacity where a direct-current source is not available, but direct-current starting, where possible, is preferable where it is desirable not to affect the A.-C. supply voltage in any way by A.-C. starting.

Fig. 2 shows the connections employed for starting by

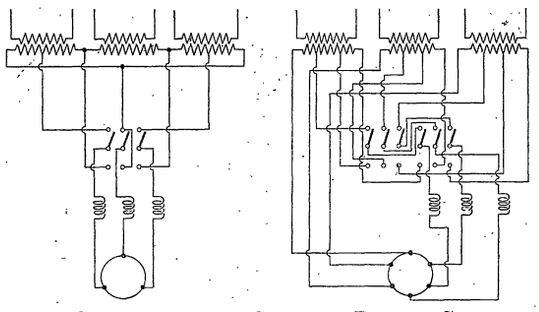

FIG. 2.—CONNECTIONS FOR STARTING ROTARY CONVERTERS BY VOLTAGE TAPPINGS ON TRANSFORMERS.

means of voltage tappings from the transformers. Since high voltages may be induced in the shunt D.-C. field winding of these machines when starting from the A.-C. side, it becomes necessary to provide a switch to break the field winding into five or six sections. Such a switch is usually fixed to the machine frame, and closed after starting. It is also necessary to provide a double-throw field switch for the same field winding in order to reverse the field polarity if necessary after starting in this way, since it is possible for the A.-C. field to run up in the wrong direction. On account of the high inductance effect of heavy capacity cables, it is advisable to fix the main low-tension transformer switch near to its transformer, so as to reduce this distance to a minimum; and since indicating apparatus is not usually connected in this circuit, a satisfactory arrangement is formed by fixing these switches on the machines themselves.

Hosted by Google

When D.-C. starting is employed, the machine is started with strong field, and synchronised with the supply voltage before connecting to the A.-C. supply. When compound rotaries are supplying power to common D.-C. bus-bars, care is necessary so that the machines are started as shunt motors from the common equalising bar and one main bus-bar; this necessitates all overload control apparatus being connected in the negative side.

SWITCHGEAR.

Fig. 3 gives a diagram of connections of the switchgear

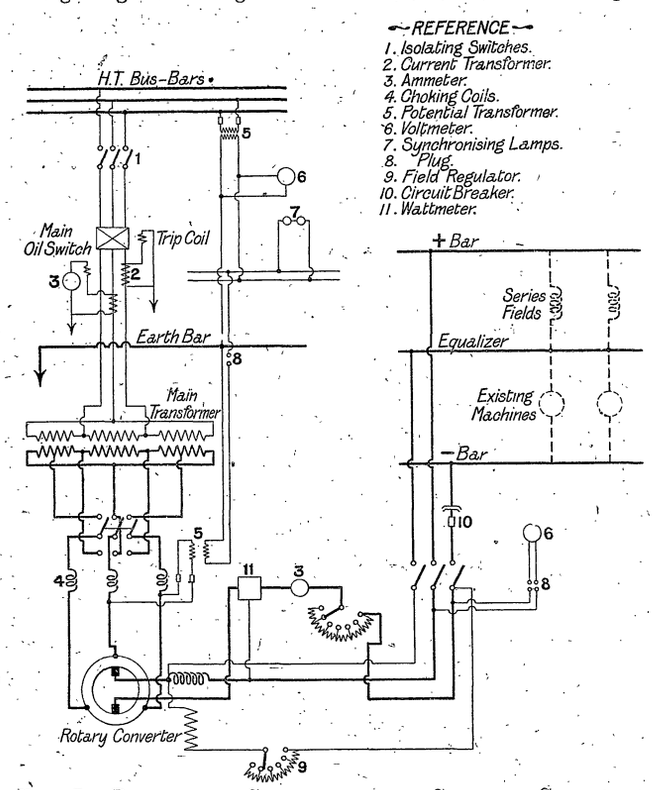

FIG. 3.—DIAGRAM OF CONNECTIONS FOR COMPLETE CONTROL OF A COMPOUND-WOUND THREE-PHASE ROTARY CONVERTER SUPPLIED BY A HIGH-TENSION INCOMING LINE.

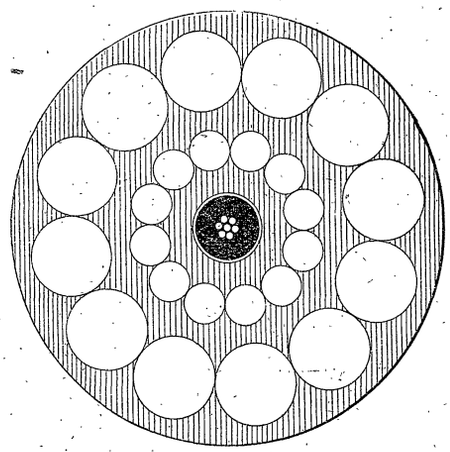
necessary for the complete control of a compound wound three-phase rotary converter supplied by a high-tension incoming line, and running in parallel with direct-current generators, and providing for both A.-C. and D.-C. starting. The various items of switchgear necessary are clearly seen from the diagram.

When starting from the D.-C. side, it is necessary first to close the equalising switch, negative switch, and circuit-breaker. The machine then starts as a shunt-wound motor with strong field between the equaliser and negative bus-bars, and can be synchronised on the A.-C. side with the supply voltage by means of the synchronoscope. When in synchronism, the transformer switches are closed, the direction and strength of field adjusted if necessary, and D.-C. end put on to the D.-C. bars.

In conclusion, it may be remarked that the rotary converter, although having been subjected in the past to adverse criticism, has still maintained its place against its rivals as far as its practical capabilities are concerned, and is employed in present-day practice probably more than any of the later forms of machines. Its efficiency is high, its operating qualities are comparatively good, and the cost satisfactorily low.



University College, London.—The second term of the session opened last Tuesday. A special course of lectures on "Advanced Electrical Measurement" commenced last Wednesday.

London Borough Councils and Testing Stations.—With reference to the recent threat of the London County Council to summons the Islington and Marylebone Borough Councils for failing to provide pressure testing stations, as required by the County Council, a Committee has been appointed to consider the best means for giving effect to the views of the Borough Councils in this matter. The conference, which was held in November last, also dealt with the question of street boxes and the necessity for removing them from the category of building structures within the meaning of Section 145 of the London Building Act of 1894.

NEW TELEGRAPH CABLE BETWEEN ENGLAND AND NORWAY

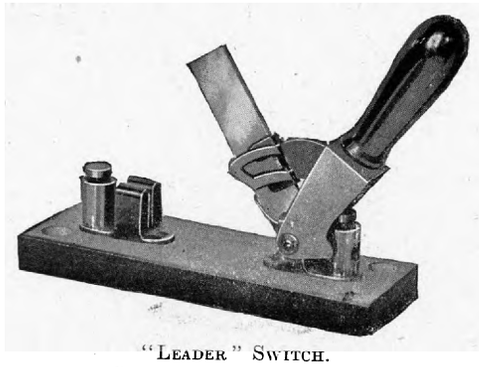
THE new submarine telegraph cable connecting England with Norway was opened to public service on January 1st.

It is the joint property of the British and Norwegian Governments, and was laid, on the expiry of the Great Northern Telegraph Co.'s concession for the Norwegian service, in accordance with the policy of the British Government of acquiring the means of international communication. Up to the present time the company has worked the Norwegian service over a single cable between Peterhead and Ekersund connecting stations at Aberdeen and Bergen respectively, and negotiations are now in progress for the purchase of this cable by the two Governments. The new cable has been laid between Newbiggin, in Northumberland, and Arendal, on the south coast of Norway, and is worked from Newcastle and Christiania respectively. The Great Northern Telegraph Co. have four cables landing at Newbiggin, including one which also goes to Arendal, but is continued on to Marstrand, and is used solely for the Swedish service. A tentative arrangement has been made whereby the Great Northern Telegraph Co. work both cables on behalf of the Governments. The new cable actually terminates at the company's cable-house at Newbiggin, but we understand that

SECTION OF DOUBLE-ARMOURED SHORE END. (FULL SIZE.)

both may ultimately be worked from a Government office in Newcastle. The rate has been reduced from 3d. to 2½d. per word.

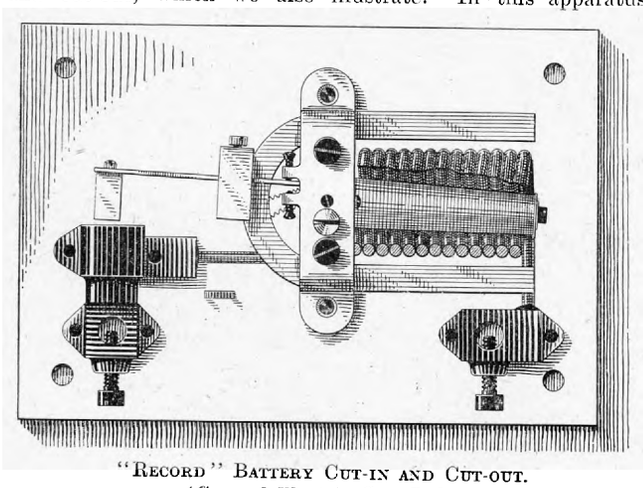
Through the courtesy of Major W. A. J. O'Meara, Engineer-in-Chief to the Post Office, we are enabled to give the following description of the cable:—The total length is 411 nautical miles or nauts, and the total weight somewhat over 3,000 tons. The cable is divided into three portions: a 4-naut length of shore-end cable at the Arendal end, a 66-naut length of light deep-sea cable, and a 341-naut length of heavy deep-sea cable. The accompanying figure shows a section of the shore end. The conductor is a strand of seven copper wires weighing 200 lbs. per naut, and the gutta-percha insulation also weighs 200 lbs. per naut. Over this is a spiral layer of brass teredo-proof tape, 4 mils. thick, and the core is then served with a layer of tanned jute yarn to form a bedding for the twelve inner galvanised iron sheathing wires, each 203 mils. in diameter. The outer 12 iron sheathing wires of 378 mils. are stranded over a further serving of tanned yarn and compound. This double-armoured type cable is employed only at the Norwegian end, where the coast is rocky. The light deep-sea section is exactly similar, but without the outer armouring; while the remainder, extending right into Newbiggin, has the same core only, being armoured with a single sheath of ten iron wires of 280 mils. diameter each. The landing point on the English coast was cleared of rock, thus avoiding the necessity for a special armoured shore-end section at this end. The weight of the shore-end type is 402 cwt. per naut, that of the light deep-sea type 103·3 cwt. per naut, and that of the heavy type cable 152·5 cwt. per naut. The specified maximum resistance of the cable at 75° Fahr. was 5·999 ohms per naut, while the specified capacity was 0·348 m.f. per naut. It should perhaps be mentioned that the cable is for telegraphic service only, and that no provision has been made for adapting it to telephone work.



The South African Institute of Electrical Engineers.—The November issue of the Transactions of this Institute contains a Paper entitled "Notes on Three-phase Motors," by Mr. P. Herd, discussing in a general manner some of the characteristics of three-phase induction motors, and the bearing these characteristics should have in determining the capacity and speed of motors to be installed. Discussions on Papers previously published are also included.

Hosted by Google

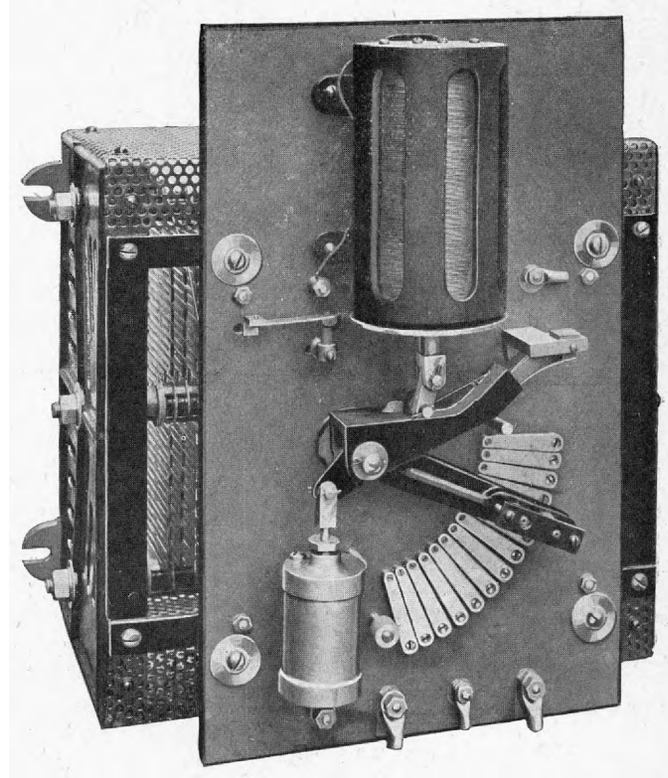
NEW ELECTRICAL SUPPLIES AND ACCESSORIES



Switches and Switchgear.

A comprehensive new catalogue of low tension switchgear has just been brought out by the General Electric Co. In addition to various forms of the well-known "Peel" and "Witton" knife switches, including a new tandem back to back arrangement of the former, we have the familiar "Adelphi" switch with laminated contacts and an entirely new line of small quick break knife switches known as the "Leader" switch, and illustrated here. These are designed

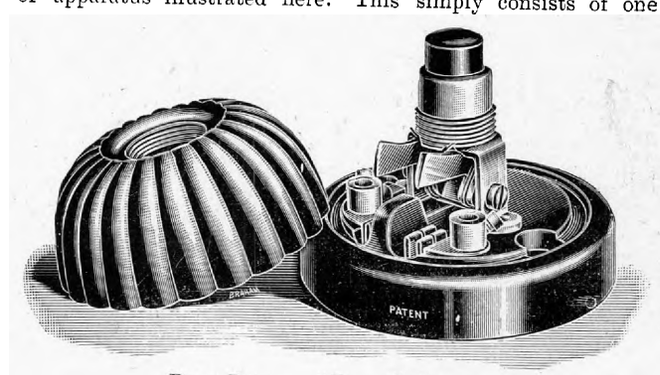
"LEADER" SWITCH.
(*General Electric Co., Ltd.*)



with remarkably few parts, and are therefore very moderate in price. We also notice improvements in the battery and resistance regulation switches, in which the brush contacts are more easily renewed than formerly. Some new patterns of voltmeter switches are also included, and among the smaller articles, attention may be drawn to a new range of angle sweating sockets. Perhaps the most important novelty is the "Record" patent automatic battery cut-in and cut-out, which we also illustrate. In this apparatus

"RECORD" BATTERY CUT-IN AND CUT-OUT.
(*General Electric Co., Ltd.*)

one end of the balanced arm carrying the main series contacts which dip in the mercury cups is provided with an iron core surrounded by a fine wire winding shunting the cups. This causes the arm to be polarised when the circuit is open in a direction depending upon the relative voltages of the dynamo and battery. If the dynamo voltage is more than 10 per cent. above that of the battery, the arm is attracted up and the switch is closed, if the dynamo voltage is lower, the arm is polarised the other way tending to hold the switch open. In either position the current in the fine wire coil tends to strengthen the permanent magnet. When current is flowing, the armature is polarised by the series coil, which surrounds it in such a direction as to be attracted by the upper pole of the magnet, and therefore to keep the switch closed. A reverse current reverses its polarity and immediately opens the switch, which, as we have already seen, is then held open by the fine wire coil. The counter-weight can also be set to make the switch open definitely at no current or at a predetermined minimum current. The list also contains particulars of a large number of patterns of circuit breakers, house service switches and fuses, and other ironclad gear.

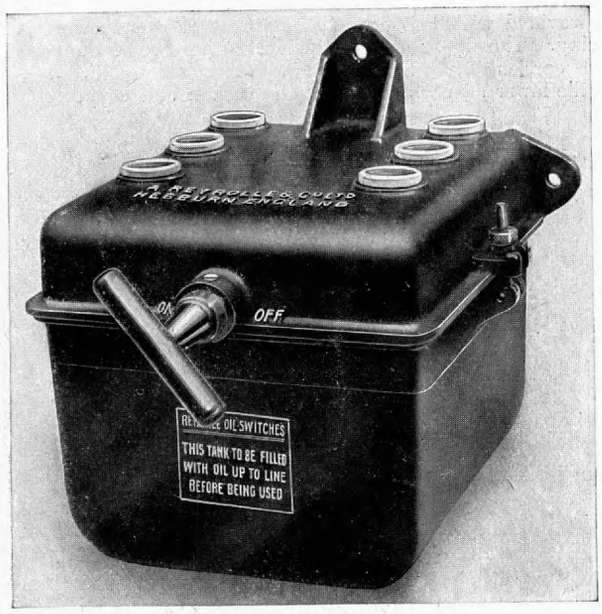


We have received from the Electrical Apparatus Co., Ltd. (Milford Works, Queen's Road, Battersea, S.W.), a leaflet describing an automatic starter of the solenoid pattern. This is provided with two levers, held together by a powerful hub-spring. The upper one is attached to the core of the solenoid and carries the main contact. The dashpot is attached to the lower arm which carries the carbon and copper contact

SOLENOID STARTER.
(*Electrical Apparatus Co.*)

plungers for cutting out the resistance. When the solenoid is energised the upper lever is pulled up with a snap, closing the main contact and starting the motor with all resistance in. The spring between the two levers is now in tension, and the lower lever is steadily pulled up, being retarded by the dashpot. The starting resistance is gradually cut out until the motor attains full speed. On failure of supply, the solenoid releases the main lever, and the circuit is broken, both levers flying back to the off-position.

To meet the demand for a push button to carry heavier currents, and of stronger construction than those designed for bells, Messrs. A. P. Lundberg & Sons (477 to 487 Liverpool Road, London, N.) have introduced the piece of apparatus illustrated here. This simply consists of one



PUSH-BUTTON "PIVOT" SWITCH.
(*A. P. Lundberg & Sons.*)

of their well-know "Pivot" switch movements adapted to be worked by a plunger instead of the ordinary dolly-head. Two patterns are made, one in which the circuit is normally open, and is closed as long as the plunger is depressed, and the other in which pressing the button breaks the circuit.

C

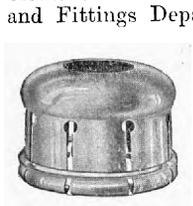
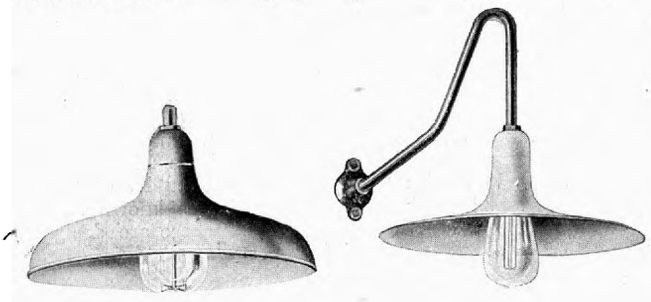
The accompanying illustration shows a new quick make and break three-phase non-automatic oil switch, which Messrs. A. Reyrolle and Co. (Hebburn-on-Tyne) have just put on the market, in the 50 ampere size. This has been designed to meet the difficulty experienced in shipyards and works, especially with squirrel cage motors, in preventing



REYROLLE QUICK BREAK OIL SWITCH.

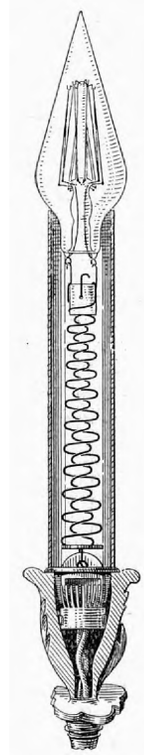
the men from trying to "inch" the motors round by means of the switch. The operating handle will remain in two positions only, full-on or full-off, and the operator is absolutely powerless either to make or to break slowly. The brushes are laminated, and ample sparking contacts are provided. The company have also issued a new leaflet describing their small totally enclosed starter with oil immersed resistances.

The Sun Electrical Co., Ltd. (118–120 Charing Cross Road, London, W.C.), have shown us three interesting switches of their Kalkos pattern, two of which have undergone very severe tests. One of these has been used to break three amperes 40,000 times, the second has broken five amperes 10,000 times, and the third has been switched on and off 40,000 times without carrying current. The contact surfaces of these three switches all appear practically as good as new, and it is almost impossible to distinguish which switches have undergone the test under current. In these switches the contact surfaces carried by the contact arm are plain circular discs which are joined by a short piece of flexible cable passing through the marmorite block which carries them. The result is that there is a certain amount of flexibility, and the contact discs adjust themselves and form an exceedingly good contact against the fixed contact springs.



Fittings and Accessories.

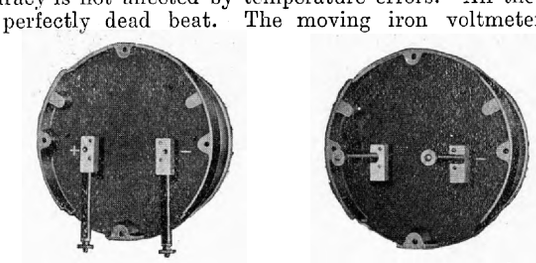
We illustrate here a new screwless gallery which Messrs. Siemens Brothers Dynamo Works, Ltd. (Incandescent Lamp and Fittings Department, Tyssen Street, Dalston), have introduced for Holophane shades. It is of a specially deep nature, in order to bring the lamps into true focus with the glassware. By this means wonderful illumination effects are obtained with the new "Stiletto" Reflectors. This gallery entirely dispenses with the use of screws, the ring slides along the outside and is pulled up when the gallery is pushed over the lip of the reflector. The ring is then pushed down and the glass is securely held. To release, the ring is pushed up and the glass pulled out. The old type of gallery with the three screws is often a cause of breakage, for if the screws hold the glass too tightly the reflector may crack through expansion. The new screwless gallery is admirably ventilated, as will be seen, and thus the cap end of the lamp is kept cool.



SCREWLESS GALLERY FOR HOLOPHANE SHADES.

Two new weather-proof reflector fittings, recently introduced to this country by The Benjamin Electric Co., Ltd. (1a Rosebery Avenue, E.C.). These are constructed of vitreous enamelled steel. The lamp-holders are made in two pieces of vitreous porcelain, all conducting parts and terminals having widest possible separation. Easy access to terminals for connecting up is provided by constructing the

DIFFUSING PATTERN DISTRIBUTING PATTERN
BENJAMIN REFLECTORS.

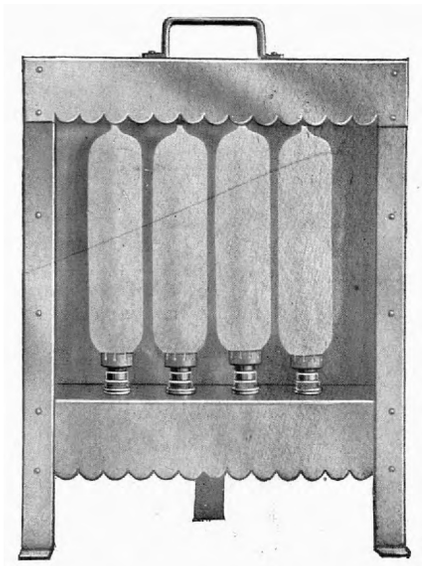


fitting in two parts. They are stocked with bushing screwed for ½-inch gas thread, and a simple but effective rubber washer arrangement is provided for preventing moisture entering the lamp-holder after inserting the lamp. Two patterns are made with diffusing and distributing reflectors, the former 12 in. in diameter, and the latter 14 or 16 in.

"FLEXALITE" CANDLE FITTING.

An entirely new candle fitting, known as the "Flexalite," has been brought out by the Sun Electrical Co., Ltd. (118–120 Charing Cross Road). The combination, which comprises several novel features, is shown in the accompanying illustration. The base consists of a piece of porcelain with a steel ribboned self-centreing collar, which may be placed in the socket of any candle-stick. Two taper screws fit into the base, and a tight grip can be obtained irrespective of irregularities in the hole in the fitting. To the porcelain base is attached an expanding spring connection, which hooks into the loops on the lamp. The opal tube is held purely by the action of this spring, and this gives a flexibility which guards the candle from damage by allowing it to deflect when knocked, and then to return to its original position. The absence of a lamp cap much improves the effect of the transparency of the tube without any of the filament requiring to be inside. The whole device is simple, durable, and affective, and can be adapted without alteration to a wide range as regards the size of the socket and the length of the tube. Only the lamp itself, which is of the metal filament type, requires to be renewed.

Simplex Conduits, Ltd. (Garrison Lane, Birmingham) have issued a new catalogue of measuring instruments, including both switchboard and portable pattern types of instruments on the moving iron, moving coil, hot wire, and dynamometric systems. The accuracy of the moving iron instrument, which is the cheapest form, is given as within 1 per cent., owing to the lightness of the moving element and the use of jewelled bearings. The moving coil, hot wire, and dynamometric types are guaranteed within 1 per cent., and this accuracy is not affected by temperature errors. All the types are perfectly dead beat. The moving iron voltmeters are



ARRANGEMENT OF FRONT AND BACK CONNECTIONS TO SIMPLEX INSTRUMENTS.

fitted with an additional resistance seven times the ohmic resistance of the copper bobbin, whilst the moving coil voltmeters have a resistance of 10,000 ohms per 100 volts. The switchboard patterns are of a flange type, open dial, or cast-iron type, and have special terminals which are interchangeable, so as to allow of their being used for either back or front connections in the manner shown in the illustration.

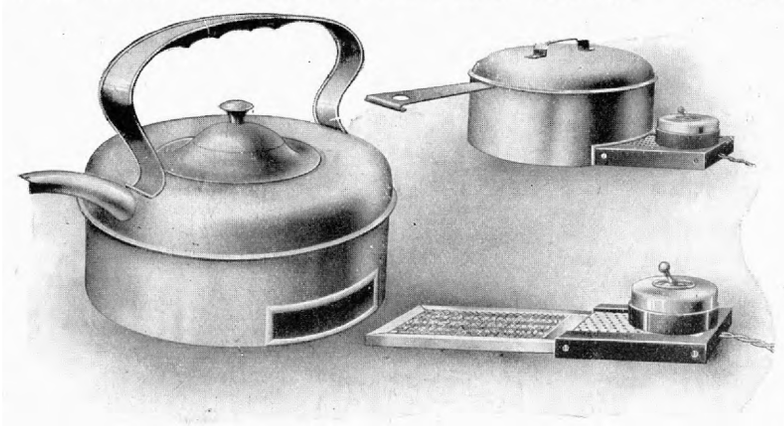
Heating and Cooking Apparatus.

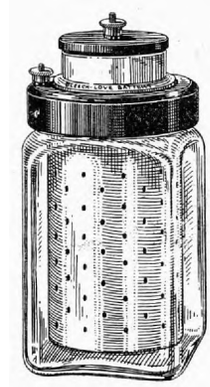


The British Prometheus Co., Ltd. (Salop Street Works, Highgate, Birmingham) have recently introduced some new designs of electric radiators and convectors at remarkably low prices. One of these is the radiator illustrated, which is

CHEAP PATTERN OF PROMETHEUS RADIATOR.

listed as low as 12s. 6d. subject without lamps. This is constructed in wrought iron with black finish. No switches are provided, and the wiring is brought direct to the lamp-holders. Switches can, however, be provided at a slight extra price. A convector is also sold in the 1,000 watt size complete with Prometheus strip elements, for 37s. 6d.

From time to time descriptions have appeared in these columns of heating apparatus on the "Quartzalite" principle supplied by the Bastian Electric Heating Syndicate, Ltd. (91 Palmerston House, London, E.C.). The heating element in these devices consists of a number of quartz tubes containing helices of a non-oxidising wire, which cause the tubes to glow at a red heat. The latest production is a device known as an "insertion heater," and consists of eight short tubes mounted in a metal framework and protected by wire network at top and bottom, as shown in the illustration. One such heater can be used in conjunction with several special but inexpensive utensils. These are provided with a chamber at or near the bottom, into which the heater is inserted. Kettles, water-boilers, tea-urns, etc., have the chamber some-



"QUARTZLITE" INSERTION HEATER.

what above the bottom, so that there is liquid all round it. The heater takes 500 watts, and will boil two pints of water in the kettle in from 12 to 15 minutes. A one-gallon boiler will boil in about 50 minutes, and, by means of a very efficient lagging, some 75 per cent. of the heat is said to be retained after 12 hours. This boiler should therefore be found of great convenience in offices, shops, etc. It should be noted that by means of the insertion heater, it is possible to convert gas-heated urns to electric heating. A 250 watt size can also be obtained.

Another recent Quartzlite production is a radiator similar in all respects to the now well-known rat-trap pattern (see ELECTRICAL ENGINEERING, July 8th, 1909, p. 631), except that the quartz tubes are vertical. The tubes are spaced in a circle round a central vertical cylinder, which acts as an efficient reflector, and the whole is fitted in an attractive looking frame with spun-metal ends and a protecting wire cage. This radiator takes 750 watts, and gives a comfortable heat with an attractive glow. It is suitable for heating small bedrooms, sitting-rooms, drawing-rooms, offices, etc., and is known as the Lighthouse radiator, on account of its appearance.

THE BLEECK-LOVE PRIMARY CELL

A NEW primary cell has been introduced by the India Rubber, Gutta Percha and Telegraph Works Co., Ltd., of Silvertown, London, E., under the name of the Silvertown Bleeck-Love Battery. It is a two-fluid cell of the bichromate type with zinc and carbon elements. The excitant is caustic soda, and the zinc, which is not amalgamated, may be left in this solution without deterioration when the cell is not in use. The depolariser is a patented solution. As shown in the illustration, the zinc is enclosed in a porous pot containing the caustic soda, while the negative element is in the form of a perforated carbon cylinder surrounding it and immersed in the depolariser. An outer vessel of glass, ebonite, or other suitable material is employed. The cell has an open-circuit E.M.F. of 2·7 volts, and the initial P.D. on closed circuit with a small current is 2·5 volts. The internal resistance is only about 0·15 ohm, and no fumes are given off. The cell is claimed to have a large current capacity, and to have a very constant E.M.F. on varying loads. The initial and recharging costs are comparatively low, and this renders the cell suitable for telegraph and telephone batteries where heavy currents are required. Among the other uses for which the cell is suitable are small wireless sets, X-ray work, lighting small lamps, charging accumulators, etc. It is claimed that two cells on one charge will run a 7 in. fan for 36 hours, or will run a 4-volt 4 c.p. lamp for 18 hours, or will charge a 20 ampere-hour 4 volt accumulator in 16 hours. A three-cell battery with tray measures 17 in. by 6¼ in. by 11¼ in. high; a ten-cell battery 28 in. by 12 in. by 11¼ in.

BLEECK-LOVE CELL.

The Turin Exhibition.—We have received from the exhibitions branch of the Board of Trade some further particulars regarding the forthcoming International Exhibition in Turin. The exhibition is to be opened on April 29th, 1911, by the King of Italy, and the site is at the end of the Corso Vittorio Emanuele II. The British section is to be a special fire-resisting building, and, with the international machinery hall, will stand on the side nearest the city. The space available in the British section amounts to five acres. Among some particulars of the industries of the province of Piedmont, in which Turin is situated, it is mentioned that the hydraulic power in use for industrial purposes in Piedmont in 1903 was 132,948 h.p., the other power in use for industrial purposes being 126,162 h.p. The yearly rate of increase in the use of hydraulic power since 1903 has been about 11,000 h.p. The concessions for new hydraulic power granted in 1909 were 13, totalling 21,784 h.p., as against 24 concessions, totalling 13,582 h.p. in 1908, and 59 concessions, totalling 104,957 h.p. in 1907. It is stated that the British Consuls in Italy report good prospects as regards the extension of British markets in Italy for electrical apparatus. Very complete precautions against fire are being adopted. The town has a fire brigade with 20 stations and over 200 men, and a force of no less than 1,200 watchmen will be employed at night in the exhibition. Hydrants fed from a special service quite apart from the town supply, will be placed about 38 yards apart, and a pressure of 90 lbs. per sq. in. will be available. Sappers and engineers will also be in readiness to blow up buildings if it becomes necessary to isolate a fire area. The British section will be separated from the only other building with which it is in contact by a fireproof wall 35 in. thick, and a passage 16 ft. wide surrounds all other parts. Thirty extra hydrants drawing water from the river will be provided, in addition to those of the Italian authorities, and these will be fed by special pumps capable of throwing 1,000 gallons per minute. Every part of the buildings will be rendered non-inflammable.

2,000-H.P. SINGLE-PHASE LOCOMOTIVE FOR THE LOETSCHBERG RAILWAY

SOME further particulars are to hand of the large single-phase locomotive built by the Maschinenfabrik Oerlikon for service on the Loetschberg tunnel route now being constructed between Berne, in Switzerland, and the Simplon

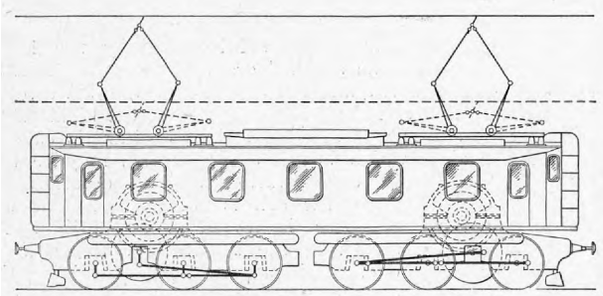

FIG. 1.—2,000-H.P. OERLIKON LOCOMOTIVE FOR THE LÖTCHBERG TUNNEL RAILWAY.
(Scale 1 in. = 15 ft.)

Tunnel connection with Italy. The equipment of this line will be on the single-phase system, with a trolley-wire pressure of 15,000 volts and a frequency of 15 cycles. The Oerlikon locomotive develops 2,000 h.p. continuously at 26 miles per hour, giving a tractive effort of 28,700 lbs. at the wheel periphery. If the connections were altered so that this normal torque were exerted at a speed of 37 miles per hour, an output of 3,000 h.p. on the one-hour rating would be obtained without any increase in weight. At starting the tractive effort can be increased to 33,000 lbs. Speed regulation can be effected from standstill to 44 miles per hour. As shown in Fig. 1, the body of the locomotive is supported on two three-axle trucks, the six wheels of each of which are coupled together. On each truck is a 1,000-h.p. motor driving, through spur-gearing, an intermediate shaft coupled to the driving axles as shown. The gear ratio is 1 to $3\frac{1}{4}$. A general view of one of these trucks, showing the commutator side of the motor, is given in Fig. 2. The motors are of the Oerlikon compensated series type, and are 12-pole machines with commutating fields produced by a special phase-displaced current. Each weighs somewhat under 9·5 tons, including gearing. They are so designed that even when developing the maximum torque at starting, the maximum voltage per segment of the commutator is 4 volts. The greatest number of segments touched by one brush simultaneously is three, and consequently there can be no serious sparking. There are no resistance leads between the segments and the armature coils, but these connections are, on the contrary, particularly heavy. By experiment, the efficiency has been found to be 90 per cent. between half-load and full-load. At the speed corresponding to a locomotive speed of 19 miles per hour, the power factor was over 95 per cent. The air-gap of these motors is 3 mm. Of the total locomotive weight of 88 tons, the electrical equipment is responsible for 42 tons. The weight per axle is under 15 tons.

The electrical equipment is divided into two portions, which can be worked independently if necessary, and the presence of two transformers renders it possible to drive the locomotive from a three-phase supply. In this case the transformers are placed in the Scott three-phase-to-two-phase connection, and each motor is supplied from one phase of the two-phase supply. A special arrangement of the two current collectors would be required, however. The motors will also run off a 400-volt direct-current supply, but for this purpose heavy series resistances for starting up would have to be provided. The transformers, each of which will deliver 2,000 K.V.A. continuously, are air-cooled by forced draught, and supply the motors with current at sixteen different voltages up to 840 volts. The low-tension windings are earthed at the middle-points, so that the maximum pressure between motor winding and earth is 420 volts. Special tappings off the transformers supply current at 300 volts for train heating. Some 100 kw. is required for this purpose for one train.

For lighting the train and supplying current for the contactor switches, a motor-generator set and battery are provided. An 8-h.p. air compressor with automatic starting and stopping gear for the collector-bow raising gear and the air brakes, and a 10-h.p. blower for the forced ventilation of the motors and transformers are also installed on the locomotive. We are indebted to the Maschinenfabrik Oerlikon for the above particulars and the illustration of the motor truck.

THE MERZ-PRICE SYSTEM

THE Merz-Price protective system, which had been described in a Paper by Mr. H. W. Clothier on December 19th before the Newcastle Section of the Institution of Electrical Engineers, was further dealt with on the following day in a Paper read before the Manchester Section by Messrs. K. Faye-Hansen and G. Harlow, entitled "Merz-Price Protective Gear and other Discriminative Apparatus for Alternating Current Circuits." After dealing briefly with the limitations of and objections to overload time-limit protection and reverse energy apparatus, the authors proceeded to set forth the essentials of the Merz-Price protective gear, and explained the simpler forms of the system, of which particulars were given in ELECTRICAL ENGINEERING of Dec. 29th (page 822), in connection with Mr. H. W. Clothier's Paper; the difference between the current and magnetic balance arrangement was pointed out, and several methods of connection were shown. The balanced voltage system for feeders was seen to require less pilot wires. In this system, however, it is not so easy to predetermine the fault current at which the relay will operate, as the fault current in one series transformer must induce an electromotive force large enough to overcome the impedance of the comparatively long pilot wires, the relays, and also of the other transformer, so that the magnetising current of the transformers will be a large part of the primary fault current; if, therefore, the relays are not designed for a comparatively low volt-ampere operating capacity, the series transformers must be very large. For this reason relays are used in many cases. It is possible, however, to use trip coils direct in the circuit for short feeders without too large series transformers being required. The balanced voltage system is similar to the balanced current system in that the series transformers have to be made larger if it is desired that the gear shall operate at a fault current small compared with the normal full-load current.

Fig. 1 shows the balanced current method adapted to the

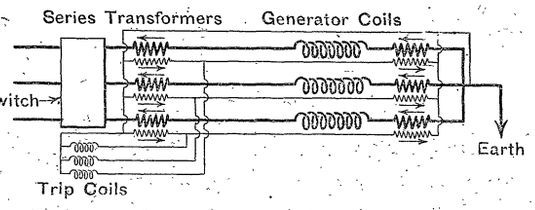

FIG. 1.—BALANCED CURRENT SYSTEM AS APPLIED TO STAR-WOUND THREE-PHASE ALTERNATOR.

protection of a star-wound 3-phase alternator. The case of a delta wound machine requires the mounting of all six transformers adjacent to the machine or the carrying of six leads from it. The authors remark that Merz-Price gear can only protect against fault to earth or between phases, and does not take care of breakdown between different parts of one phase or loss of field or loss of power, so they do not recommend its use alone for generators.

The connections for transformer protection, and the use of time-limit fuses in conjunction with the relays, was then explained. It was pointed out that a breakage in the pilot wire circuit prevents the operation of the balanced voltage system in case of fault, and is difficult to locate without frequent testing of the pilot wires. Such a breakage with the balanced current system or balanced magnetic system results in the immediate isolation of the section in which the fault occurs. A break in trip coil or trip coil circuit, however, renders all the systems inoperative. With the balanced voltage system, the balancing of the transformers must be most carefully carried out, whilst in the balanced current system this is not necessary, as the ratio of the series transformers decides this point, provided the transformers are chosen of a size suitable for the work. The balanced voltage system can be used for protection only, whereas the balanced current or magnetic systems may be used in many cases for measuring purposes in connection with instruments. The balanced current and magnetic systems require less power than the balanced voltage system, due to the fact that the operating series transformers on the latter system have to overcome the impedance of the opposing series transformers, in addition to the relays or trip coils, whereas in the former system the impedance of the relay or trip coil only has to be overcome. The authors consider that the balanced current system, wherever applicable, has an advantage compared with the balanced voltage system, if it is possible to adopt it without an increase in cost. They also advocate the use of the fault current itself for tripping without relays wherever possible.

In the design of balanced voltage gear, the following special points have to be kept in mind: The fault current at which the gear is to operate must be well within that expected in case of breakdown when the minimum plant is running in the generating station. Thus the maximum short-circuit current to be expected through a healthy feeder when the maximum available plant on the system is in operation, should not be large enough to raise the voltage between the pilot wires to a value endangering the safety of the pilot-wire insulation, or to cause a capacity current in the pilot-wire circuit sufficient to operate the relays. Considerable margin must be allowed for any extraordinary high-frequency phenomena which may be expected on the system. The series transformer secondary voltages have to be balanced with extreme accuracy against each other. These points were elaborated at some length in the Paper, and quantitative data for various cases were gone into. The authors hold that the reliability of the balanced voltage system can be increased and the maintenance reduced if in place of direct-current tripping alternating-current tripping be adopted where the tripping is directly dependent on the current flowing under fault conditions. This can be carried out by using special series transformers in each phase for tripping, the relays closing the circuit of these transformers through the trip coils.

An improved arrangement for feeders is then described which does away with both relays and batteries. The method is shown diagrammatically in Fig. 2 as applied to a three-

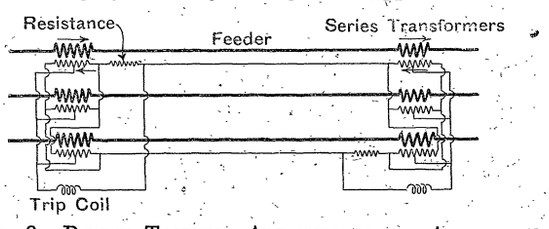

FIG. 2.—DIRECT TRIPPING ARRANGEMENT AS APPLIED TO FEEDERS.

phase circuit using two pilot wires and one trip coil at each end. The principle of the method which can equally well be applied to feeders is that of the balanced current system whereby equipotential points (under healthy conditions) are obtained by means of tappings from the transformers secondaries and additional resistances. The centre point of each transformer is connected to the end of a small resistance, approximately equal to the resistance of one of the pilot wires. Under normal conditions of operation, the middle point of the secondary of the series transformers is at the same potential as the end of the resistance, and consequently the trip coil may be connected across these two points without any danger of tripping under all conditions of load. Immediately a fault occurs in the section of the feeder protected by the two series transformers, the middle point of the series transformer and the end of the resistance are no longer equipotential points, and current flows through the trip coil thus tripping the switch. In this system there is no necessity for the accurate balancing of the transformers, and a break in a pilot wire cuts off the feeder at once.

A detailed comparative table is given showing the currents, voltages, &c., in the different circuits, and other quantitative data for four modifications of the system for four different fault conditions, and it is finally concluded that the balanced voltage system with three pilot wires for D.C. or A.C. trip with relay, or the balanced current system with two pilot wires and A.C. trip without relays can be all used satisfactorily, provided the necessary attention is paid to the design of the apparatus and the characteristics of the system to which they are applied carefully studied, but that the balanced voltage system with A.C. trip without relay with three pilot wires is not so suitable.

The balanced current system with resistances is well suited to the protection of branched feeders, and with this arrangement two pilot wires can be used, as shown in Fig. 3, due to the fact that three trip coils instead of two have to be operated; the fault current required for tripping is increased

Hosted by Google

approximately 50 per cent. For all the above systems the sensitiveness can be improved by increasing the size of series transformer and the secondary voltages.

In the authors' opinion, the most effective method of protecting parallel feeders is by the use of the Merz-Price

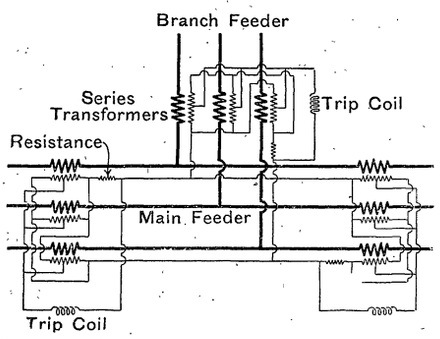

FIG. 3.—BALANCE CURRENT WITH RESISTANCES AS APPLIED TO BRANCH FEEDER.

gear, and most of the data given above are applicable to this case. Other methods of protection have been proposed, one of which is shown in Fig. 4. This was introduced by the British Thomson-Houston Company. With the series transformers interconnected as shown at the sub-station end, no potential will exist between *a* and *b*, provided the secondaries are carrying the same currents. If, however,

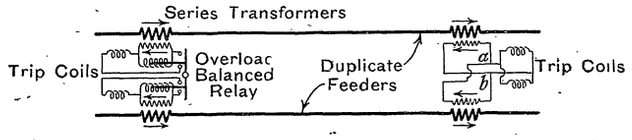

FIG. 4.—B.T.-H. SYSTEM FOR PROTECTION OF PARALLEL FEEDERS.

a fault occurs in one of the feeders, then the currents in the primaries of the two series transformers flow in opposite directions. This method, however, does not discriminate as does the Merz-Price, in that both the healthy and the faulty feeders are cut off at the same time.

This method of protection can be made discriminating by using such an arrangement as shown in Fig. 5, where A and B represent two incoming 3-phase feeders. The currents on these feeders are balanced against each other on separate transformers. The extra windings on the balancing transformers *c* and *d* are led to a discriminating reverse-current

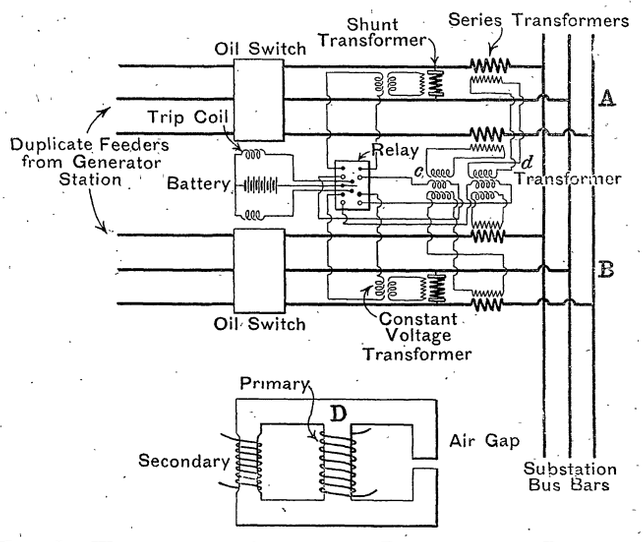

FIG. 5.—WESTINGHOUSE SYSTEM FOR PROTECTION OF PARALLEL FEEDERS.

relay. As normally no voltage is induced in the extra windings, no current flows through the relay coils. On reversal of current in one feeder due to a fault in the feeder, current flows through the relay, which is deflected to one side or the other depending upon which feeder is faulty. This method was introduced by the Westinghouse Company in 1905. In order to guard against the voltage failure in some measure, the special shunt transformer shown in Fig. 5 is adopted. It is designed with three legs, on the centre one of which the primary winding is placed. The secondary winding is wound round the left-hand leg, which at the normal voltage is highly saturated. The right-hand leg is built with an air-gap. Assuming that at full voltage the flux produced by the primary coil divides equally between the two outer legs, then with a lower primary voltage the flux will divide so that a greater proportion than half passes through the leg on the left, since the permeability is greatly increased as the flux is reduced. Thus the voltage induced in the secondary winding will not fall so quickly as the primary voltage.

The relays are usually constructed in a very simple manner. The British Thomson-Houston Company's and the Westinghouse Company's relays are very similar in construction. In the latter (Fig. 6) the weight of the armature A is counter-

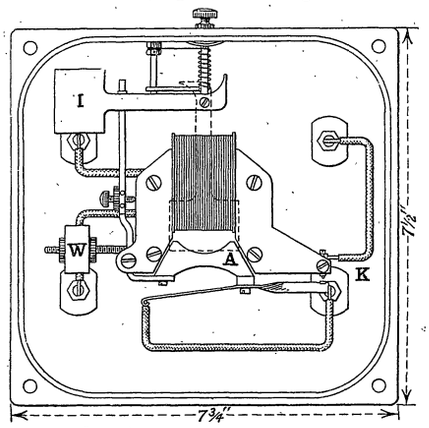

FIG. 6.—WESTINGHOUSE RELAY.

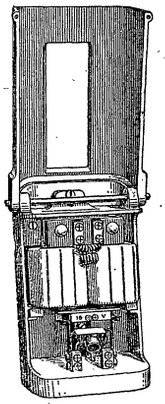

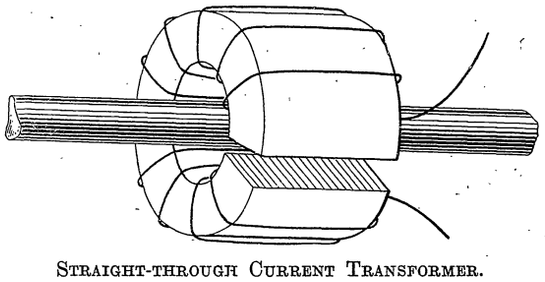

FIG. 7.—REYROLLE RELAY.

balanced by an adjustable weight W, and the trip-coil circuit is closed at the contact K. On the relay tripping, the indicator I falls and denotes on which phase or between which pair of phases the fault has occurred. In the British Thomson-Houston Company's relay the trip-coil circuit is closed at two points, one at each end of the armature. The Reyrolle relay (Fig. 7) differs somewhat in form from the two previously described, and is not arranged for automatically re-setting itself when a fault is cut off. This latter feature serves as an indicating device and renders a special indicator unnecessary, but in the form shown necessitates opening the case and re-setting the relay before the opened switch is closed again.

DISCUSSION.

Mr. P. V. HUNTER (Messrs. Merz & McLellan) called attention to the necessity for bearing in mind the great rise of voltage that might occur in the secondaries of the current transformers under fault conditions. Sometimes it would be as high as 700 volts. He also particularly emphasised that the apparatus must always be designed in reference to the maximum fault current possible, and not to the full load current. The author had described a large number of methods of connection; only about three, however, were actually in use. He rather questioned whether in the author's arrangement shown in Fig. 2, that in the event of a pilot wire breaking, there would always be enough current in the feeder to work the relays. An objection to the author's system of direct tripping was the number of parts that had to be balanced. In the figures given in the Paper the author had taken transformers of very much larger size than those used on the North-East Coast system.

Mr. H. W. CLOTHIER (Messrs. A. Reyrolle & Co.) showed a piece of cable which had developed a fault between phases on

STRAIGHT-THROUGH CURRENT TRANSFORMER.

the Glasgow system, where Merz-Price protection was in use. The small damage done to it showed how promptly it had been cut out. He then proceeded to describe the actual form of transformer used on the Newcastle system; this is shown diagrammatically in the accompanying figure. The primary is a

Hosted by Google

straight bar, and the core is made with an air gap, which afforded a ready means of adjustment for balancing. The input in less than 5 volt-amperes as compared with the 41 and 125 volt-amperes of the author's transformers. They have a straight line characteristic up to about thirty times full-load current. The relay shown in Fig. 7 could be arranged to be self-resetting. In the North, the current balancing system of feeder protection known as neutral wire balancing, had been used, but was abandoned in favour of electrical balancing. The author's direct trip system was interesting, but evidently required large and expensive transformers. Auxiliary tripping had the advantage of permitting the switches to be tripped periodically to see that all was in order.

Mr. E. B. WEDMORE (British Thomson-Houston Co.) paid tribute to the excellence of the Merz-Price system. The circulating current system shown in a number of the author's figures has also been worked out by his company. He preferred single-turn transformers, and sensitive relays to direct tripping. His own system, which had been described in the Paper, could be made discriminating by the addition of reverse current relays normally short-circuiting the respective trip coils. He also put in a plea in defence of the modern reverse current relay, which was a very different piece of apparatus from that condemned by Messrs. Merz and Price. Finally, he pointed out that there were many cases where parallel feeders were preferable to inter-connectors, where very simple and inexpensive protective arrangements could be employed.

Mr. A. E. MCKENZIE (Manchester Corporation Electricity Department) mentioned that 10 sets of feeder protection gear were on order for the Manchester system. They had used the Merz-Price system with success on their 4,000 kw. generators, and were about to apply it to the 6,000 kw. generators at Stuart Street. All the feeders recently laid in Manchester had pilot wires. He quite agreed that indirect was preferable to direct tripping.

The authors, in their reply, defended their large transformers as being more reliable for systems smaller than that of Newcastle, where the fault current had a lower ratio to the load current. They thought that the advantages of single turn transformers were overrated. They did not agree with Mr. Wedmore's use of reverse current relays to make his system discriminative.

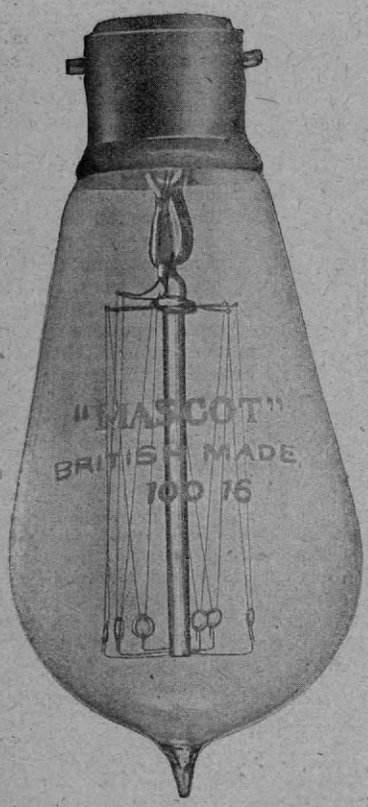
THE WIRING CONTRACTOR'S POINT OF VIEW

THE "Electrical Record" of the *Australian Mining Standard* has called attention to the fact that there has been trouble owing to the importation of poor-grade and faulty wire and cables into Australia. The matter, our contemporary says, has come under the notice of the Minister of Customs, and importers have been officially notified that they should safeguard their business interests by having adequate tests applied to consignments before taking delivery. "The insulation in the cheaper grades of wire and cable," the article continues, "is apt to be of the poorest quality, and sometimes there is remarkably little of it. In order to make up for a 5 per cent. duty imposed, the insulating material is impoverished with respect to its rubber contents, and the quantity also is reduced. The thickness of the rubber under the braid and tape is often only 22 to 24 mils. thick, instead of 35, as specified by the rules for an 18 gauge wire. Other sizes will be found to vary similarly." The rules referred to are those of the Australian Fire Underwriters' Association, and the dielectric thickness quoted above agrees with that specified by the Engineering Standard Committee in this country. Our contemporary does not state whether the wires and cables to which exception is taken are of British or foreign manufacture, but we trust that the warning will result, not only in ensuring greater care being exercised by the Australian buyers, but also in an improvement in the insulated wire exported. We have reason to believe that it is not only Continental firms who are the sinners in this respect, but that British firms—even those of C.M.A. standard—have at times been tempted to export cables of a quality that would certainly not be accepted for wiring work of a good class in this country. The secret of what are the requisites of "Association" cable other than a label with a particular colour and inscription, has never been divulged, so perhaps it would be futile to ask whether the class of cable which members of the Cable Makers' Association export is of equal quality. The buyer of British cable, both at home and abroad, is becoming impatient of the methods of the Association, and he has a right to demand some more definite assurance than is afforded by a buff-coloured label, that the function of the Cable Makers' Association is to keep up quality as well as to keep up prices.

While the conference between representatives of the Municipal Electrical Association and the Electrical Contractors' Association is proceeding leisurely, with occasional adjournments and postponements, it may be opportune to remind those who are interested in the subject that an abortive attempt to hold a similar conference on exactly the same subject was made nearly eight years ago. On April 29th, 1903 (a better date would have been 28 days earlier), a discussion on this very same subject of municipal wiring took place at Anderton's Hotel, London. It was organised by the London Electrical Contractors' Association (the predecessors of the present E.C.A.), and representatives of the electricity supply undertakings attended by invitation. At the conclusion of the discussion, a Committee of representatives of supply undertakings were appointed to confer with representatives of the Contractors' Association, with a view to an amicable settlement of their differences being arrived at. We believe we are right in saying that no meeting of this Committee was ever convened. Mr. Rashleigh Phipps was President of the London Electrical Contractors' Association at that time, and perhaps he can tell us why the proposal fell through.

An amusing incident occurred at a special meeting of the Islington Borough Council on Friday. A few weeks back the Lighting Committee of the Council recommended that they should be authorised to put into force the powers which they possess under the London County Council (General Powers) Act, 1906, to wire premises and hire out apparatus, etc. At the Council meeting on December 16th these recommendations were rejected, and as a result the Chairman of the Lighting Committee reported to the Council that that body had resigned. This report was on the agenda for the meeting on Friday last, but when it was reached the Mayor refused to allow it to be put to the meeting or to be discussed, as he had been advised that this method of resignation was *ultra vires*. The facts are that 12 out of 17 members resigned, and signed a letter to that effect, but according to the Standing Orders of the Council, any member resigning from a Committee must intimate, independently, his intention to the Town Clerk, who reports to the Council in due course. If the 12 members of the Lighting Committee send in their resignations in the proper manner, the matter will be reported to the Council meeting on January 20th.

At Worcester there is also some internal friction on the same question. Like many others, the Worcester undertaking has been hit very hard by metal filament lamps, and anxiety has naturally been manifested to obtain fresh business as a set-off against the loss of revenue. Not having trading powers, it had been thought possible to get round the law by the Department acting as agents for apparatus. The local contractors opposed this arrangement, although it was explained that all the work of fixing any such apparatus sold in this manner by the Corporation would be passed on to them. The Corporation threw out the Committee's suggestion, and the Chairman resigned. A new Chairman has been appointed, but he has made it clear to the Corporation that if he finds it necessary, in the interests of the electricity undertaking, that the powers which have been refused are essential to its well-being, the Council must give way, or he will not continue in office.



Ozone Treatment of St. Petersburg Water.—The Russian Siemens & Halske Company have installed, in conjunction with the Lahmeyer Company, a large plant for the electrical sterilisation of water for the public water supply of part of the city of St. Petersburg. By means of an electrical discharge, air with a high percentage of ozone is prepared, and this is brought into intimate contact with the water. The plant is the largest of its kind, and treats some 50,000 cubic metres of water daily. The system employed is a combination of the Siemens ozonising apparatus and the sterilising towers of the Compagnie de l'Ozone, Paris. It is probable that the system will be extended later to the whole of the water supply of the city.

Durability of Arc Lamps.—The Union Electric Co. send us the following report from one of their engineers: "You will probably be amused to hear my little experience previous to the order being secured for the lamps for the above. We were in competition with the 'Y' and 'X' lamps. When I went to start up the lamps I found several were not fixed, and were about being slung up. The wireman was on a crane, electrically equipped, but hand-worked from the floor. He was pulling up the lamps by a light rope, and had one half-way up when the man on the ground worked the crab of crane sideways instead of travelling forwards. The rope was cut in two, and the Excello dropped 16 to 18 feet on the wood block floor. The floor was cut a bit. I thoroughly examined the Excello, and with the exception of the slightly bent striking rod and broken economiser ring, no damage was done, and the lamp was running in half an hour. I insisted to the general manager that before a fair comparison could be made a similar combined bending and reliability test should be applied to the competitive lamps. The general manager was very surprised that the lamp was not ruined, as he saw it fall."

A NEW METHOD OF SUPPORTING LAMP FILAMENTS

MR. R. S. HORVATH (47–51 Standen Road, Southfields, London, S.W.) has brought us samples of an improved form of his "Mascot" lamp. The improvement is in the support of the filament at the pip end of the lamp. One of the difficulties in manufacturing metal filament lamps is to make sure that this support is sufficiently flexible, and yet sufficiently strong. If it is too rigid the filaments are apt to break in transport, or on contracting after use; on the other hand, if the arms supporting the filament are made of wire which is too thin, although this allows for the contraction, the hook is liable to bend out and release the filament when hot. In Mr. Horvath's new lamp, which we illustrate, it will be seen that thin flat circular links are inserted between the wire hooks and the filament. A great increase in flexibility is thus attained, and at the same time the wire hooks can be thin and springy, as they do not become so hot as they would do if in direct contact with the filament. Mr. Horvath, who informs us he himself was the maker of the first metal filament lamp made in this country, has provisionally protected the device (Patent No. 27,401 of 1910).

The sale of these new lamps is in the hands of Messrs. Galsworthy, Ltd., 15–16 Newman Street, London, W.

CORRESPONDENCE

LAMP DIMMERS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In your last issue you publish a letter from Mr. George Wilkinson, in which the following sentence occurs: "The advertisement includes a Faraday House certificate of a test on one of the switches, but this certificate *carefully avoids* all reference to the very heavy current consumption taken by the resistance."

We do not for a moment wish to suggest that Mr. Wilkinson questions the impartiality of the Report issued by Faraday House, but we regard the above sentence as being unfortunately worded. We were not instructed to report on the switch as a current-saving device, but were specifically asked to make tests of its regulating power and insulation. To have included "candles per watt" in our certificate would have been to volunteer to give our clients experimental data for which they had not asked, a course which is obviously inconsistent with professional etiquette.

In case any misapprehension may have arisen in the minds of those who are not familiar with the character of the Reports issued by this Institution for the last twenty years, we should be obliged if you would publish this letter.

Yours faithfully,

ERNEST A. NASH,
Secretary and Business Manager.

The Electrical Standardising
Testing and Training Institution,
Faraday House,
Southampton Row, W.C.
January 9th, 1911.

Wireless Telephony.—Experiments are being carried out by the French cruisers *Justice* and *Vérité* with the Jeance-Colin system of wireless telephony. It is stated that satisfactory results have been obtained up to a distance of 72 nautical miles. The apparatus employed was constructed by the Compagnie Générale Radiotélégraphie.

THE LEPEL PATENT

AFTER litigation extending over a period of nearly three years, Baron E. von Lepel has been granted a patent in Germany for his wireless telegraph oscillation generator comprising a series of metal discs separated by rings of paper. The grant was opposed by the Gesellschaft für Drahtlose Telegraphie (the owners of the Telefunken system), but the final result after appeal is that the Lepel patent has been granted, while a subsequent application by the Gesellschaft für Drahtlose Telegraphie, describing a similar device, has been refused. This is said to be the fundamental patent of the Telefunken system, which is almost universally employed in Germany. We understand that the Anglo-German Wireless Syndicate, Ltd. (the owners of the Lepel patents) will take proceedings to enforce their rights in Germany, in view of the fact that most of the apparatus used by the German Government and principal shipping companies now comes under the Lepel patent. This is all the more interesting in view of the efforts of the German Government to bring about the exclusive adoption of the Telefunken system as the standard in Germany.

It will be remembered that the British Patent Office granted both the British patents equivalent to the above German patents, but that the Gesellschaft für Drahtlose Telegraphie only obtained their patent on condition that a reference was inserted in the specification to the Lepel patent which is of earlier date. This decision of the Comptroller-General was accepted by the Telefunken company, but an appeal against the grant of the Lepel patent by Mr. Valdemar Poulsen, whose original opposition was unsuccessful, has yet to be heard. (*See* ELECTRICAL ENGINEERING, September 8th, 1910, p. 578.) We understand that the success of the Lepel company, both in Germany and England, is chiefly due to the efforts of Mr. Albert Holt, the chairman of the company.

An agreement between the Anglo-German Wireless Syndicate, Ltd., and the Compagnie Générale Radiotelegraphie, who originally exploited the Rochefort system, will be completed next week. The latter company has a large factory in Paris, and will take over all the Lepel patents except those of England, Germany, and the United States, which will be controlled by the Anglo-German Wireless Syndicate. The French company supplies the French and Belgian Governments, and has already installed Lepel stations in post offices at Brussels and Paris. The latter station (in the Rue des Plantes) is in communication for experimental purposes with the English station at Slough, described in ELECTRICAL ENGINEERING, September 15th, 1910, p. 591.

ANSWERS TO CORRESPONDENTS

Correspondents must in all cases send their names and addresses with their queries, and, if they do not desire the reply to be published after their own name, should add a "nom de plume." Questions should be addressed to the Editor, ELECTRICAL ENGINEERING, *203–6 Temple Chambers, Temple Avenue, London, E.C. The Editor will not guarantee to answer all questions in this column, and the enclosure of a stamped and addressed envelope is therefore desirable. Books recommended will be forwarded on receipt of a remittance for the amount mentioned.*

J. PERREN.—We cannot refer you to any municipal undertaking which, after being found unsuccessful, has been leased to a company. A proposal of this character was made in 1908 in connection with the Bath Corporation works, but the Board of Trade refused to sanction it, on the grounds that it was contrary to their practice to allow the transfer of an undertaking for which the full capital expenditure was being paid *plus* a further sum as consideration, or to permit a company to lease the works in perpetuity. We think it may be taken that the Board of Trade would not object to the transfer of an undertaking upon suitable terms, but the Board does not countenance the bartering of undertakings by municipalities. At Willesden, in 1904, the Council's generating station was purchased by the North Metropolitan Electric Supply Co. for the purposes of their larger undertaking, and a "bulk" supply agreement entered into, the Council still supplying the electricity to consumers.

J. A. HOPKINS.—Your forty 16 c.p., 50-volt metal filament lamps will take about 16 amperes. We should advise a 1½ kw. 55-volt dynamo, so as to allow for future additions. This would give 27 amperes at 55-volts when fully loaded. We think you will find the other information you require in the following books:—"Theory and Practice of Electric Wiring," by W. S. Ibbetson (5s. net); "Practical Electrician's Pocket Book and Diary, 1911," (1s., or by post 1s. 2d.); "Institution of Electrical Engineers' Wiring Rules" (6d. net, by post 7d.) Shall we send you these?

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published January 5th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

20,743/09. **Motor Control.** M. MILCH (Hungary). The speed of an induction motor is regulated by supplying current at a variable frequency to the rotor from a frequency transformer. Current of the frequency of the slip of the motor is supplied to an auxiliary motor driving the frequency transformer or to driving windings arranged on the stator of the frequency transformer itself. One figure.

28,947/09. **Meter.** E. T. RUTHVEN MURRAY (London). Various forms of an instrument termed an assessmeter are described. The object of the device is to indicate the maximum demand which a consumer may make. Should the demand exceed the limit indicated, a dimming switch comes into operation, and the consumer may either decrease his demand or increase his limit by moving an indicator on the assessmeter. He cannot, however, decrease the limit indicated. A scale of fixed charges per quarter is fixed on the meter, and on increasing the limit of current, the indicator points to a higher charge or assessment. The instruments described work on the hot-wire or other principles in which the heating effect of the current is employed. Eleven figures.

2,525/10. **Motor Ignition and Lighting.** A. H. MIDGLEY and C. A. VANDERVELL (Acton Vale). A variable-speed, constant-output dynamo (Spec. 16,447/09) is mounted on the same shaft with the distributor, and is used both for ignition and for charging the lighting battery. A special contact device for retarding or advancing the spark is described. Three figures.

2,700/10. **Petrol-Electric Vehicles.** W. A. STEVENS (Maidstone). Two motors are employed, each one being suspended from a tube at right angles to the chassis frame and driving one of the rear wheels through a chain on the inner side of the frame. The motors are suspended one behind the other, and the driving chains are of unequal length. This enables a chassis of normal width to be used while giving accessibility to the motors. Two figures.

7,331/10. **Manufacture of Metal Filaments.** H. MADDEN and W. G. HOUSKEEPER (Philadelphia, U.S.A.) A heating process specially adapted to filaments prepared by squirting a tungsten paste through a die, consists in subjecting every portion of the continuous filament to different degrees of heat successively by passing it through a series of contacts which cause currents of different values to flow through the portions between different contacts. Three figures.

17,380/10. **Trolley Head.** K. ENGEL (Berlin). The trolley wheel is mounted on a forked holder which has a stem sliding against the action of a spring in a tube or sleeve attached to the end of the trolley pole. The holder is attached to the sleeve by a toggle lever or lazy-tongs device. When the pole is shaken by passing over a switch the spring presses the wheel upwards and compensates for any downward movement of the pole. Three figures.

22,110/10. **Ward-Leonard Control.** SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens-Schuckertwerke-Ges.*). In a rolling-mill or other plant controlled on the Ward-Leonard system, the main motor is given a series characteristic (*i.e.*, large turning moment with moderate armature current) and yet can be reversed without reversing heavy currents. This is effected by connecting the motor field in series with the generator field to a D.C. supply at constant voltage. Both fields are also influenced by an auxiliary dynamo, the voltage of which depends upon the armature current of the main motor and can also be regulated by hand. When the load increases, the main motor field is strengthened automatically and the generator field weakened by the influence of the auxiliary machine. Two figures.

24,810/10. **Manufacture of Metal Filament Lamps.** A. S. KNIGHT (Newark, New Jersey, U.S.A.). This specification describes an apparatus for winding filaments on their zigzag carriers, in which the filament is kept taut during the mounting by means of a friction device. On breakage of the filament, the rotating part of the apparatus stops automatically. One figure.

Opposition to Grant of Patents

19,872/09. **Electrical Propulsion of Ships.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). The grant of this patent has been allowed in spite of opposition by Mr. W. P. Durtnall. The specification was abstracted in ELECTRICAL ENGINEERING, June 23rd, 1910, and describes a system with an induction motor and a low-pressure turbine on each shaft. At high speeds both are used, while at low speeds only the motors are used. Mr. Durtnall desired the insertion of a reference to his patent covering an electrical reduction drive with polyphase machinery, but the Comptroller has not considered this necessary.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Insulators for H.-T. transmission line] 7,212/10.

Dynamos, Motors, and Transformers: BRUCE, PEEBLES & CO. and DE LA COUR [Machines] 24,137/09; WALKER [Machines] 30,482/09; SIEMENS BROS. DYNAMO WORKS (*Siemens-Schuckertwerke Ges.*) [Polyphase commutator machines] 23,633/10.

Electric Ignition: KUHN [Sparking-plugs] 12,133/10; SOC. INDUSTRIELLE DE DELLE [Connections to sparking-plugs] 12,593/10 BRITISH INSULATED & HELSBY CABLES, LTD., and AITKEN [Portable shot-firing generator] 19,659/10.

Electrometallurgy and Electrochemistry: SOC. ANON. ELECTROMETALLURGIQUE (*Procédés Paul Girod*) [Steel refining] 26,588/09 and 27,003/09; JOEL [Electrode separators for batteries] 29,511/09; HENRI, HELBRONNER, and VON RECKLINGHAUSEN [Sterilisation of liquids] 30,397/09; SMITH and DEAKIN [Electroplating barrel apparatus] 7,226/10.

Heating and Cooking: PRICE [Heating apparatus] 29,411/09.

Incandescent Lamps: ELECTRIC EXPORT WERKE GES. and GOTTSCHALK [Portable lamps] 28,079/10.

Storage Batteries: JOEL [Plate separators] 29,511/09.

Switchgear, Fuses and Fittings: BROADBENT [Switches] 29,339/09; KEY ENGINEERING CO. and NAGEL [Wiring conduit] 29,350/09; SUNDERLAND and PILLINGER [Automatic electrical control of engines, dynamos and batteries] 29,944/09; ADAMS MANUFACTURING CO. (*Cutler Hammer Mfg. Co.*) [Motor controllers] 4,794/10; BROOKER and HOOPER [Lampholder locking device] 6,132/10; VIETTE [Bell call indicator] 18,778/10.

Telephony and Telegraphy: AMERICAN AUTOMATIC TELEPHONE CO. and GOODRUM [Automatic telephone systems] 29,963/09; WOOD [Telegraphy] 1,287/10; GOLDSTEIN [Central battery signalling system] 16,332/10; EISENSTEIN [Oscillation generator for wireless telegraphy] 16,364/10.

Traction: HEILMANN [Spring-suspension for vehicles] 5,276/10; W. R. SYKES INTERLOCKING SIGNAL CO., BOOT, and TARRANT [Electrically operated signalling system] 6,743/10.

Miscellaneous: COWPER-COLES [Lamps] 29,849/09; STEWART [Ventilating apparatus] 29,937/09; SWIFT and BAXTER [Electric clocks] 4,936/10; AFFLECK and PILLING [Electric driving of roundabouts] 9,538/10; BLOXAM (*Siemens & Halske A.-G.*) [Manufacture of glass] 16,441/10; SIEMENS BROS. & CO. (*Siemens & Halske A.-G.*) [Electromagnets with removable cores] 19,971/10; BOULT (*Normal Zeit. Ges.*) [Electric winding of clocks] 23,773/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: SIEMENS-SCHUCKERTWERKE GES. [Reversing of polyphase motors] 28,661/10; ALLGEMEINE ELEKTRICITÄTS-GES. [Motor control] 29,309/10.

Electrochemistry: LE NITROGENE SOC. ANON. [Separation of oxides of nitrogen] 28,933/10; WALLACH [Artistic copper articles] 17,262/10.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Distribution Systems, &c.: BRITISH THOMSON-HOUSTON CO. and E. B. WEDMORE [System of protection] 19,210/05.

Dynamos, &c.: B. G. LAMME [Rotor field system with distributed embedded winding] 20,616/02.

Switchgear, &c.: T. VON ZWEIGBERGK [Motor controllers] 18,947/01; A. P. and G. C. LUNDBERG [Wall plugs] 20,461/02; O. L. PEARD and F. DEW [Fuses for high voltage and heavy currents] 20,483/02; BRITISH THOMSON-HOUSTON CO. and E. B. WEDMORE [Reverse-power cut-outs for alternators in parallel] 19,210/05.

Telephony, &c.: W. L. WISE (*C. L. Buckingham, U.S.A.*) [Printing telegraphic apparatus, perforators, &c.] 20,682-3-4/02; J. GRAY [Telegraph pole brackets] 20,102/03; W. M. STILL [Coin-freed telephone apparatus] 18,924/05.

Traction: A. BOULT (*N. A. Christensen*) [Motor-driven compressor for air-brakes] 19,833/98; A. N. CONNETT [Collector ploughs for conduit tramways] 18,879/01; T. VON ZWEIGBERGK [Controller with electric braking positions] 18,947/01; A. N. CONNETT [Conduit construction] 19,062/01; A. M. CAREY [Permanent way] 20,508/04.

Miscellaneous: H. MCPHAIL [Superheaters] 20,853/02; J. MACLEAN [Hair-brush with electric current attachment] 20,100/03.

Hosted by Google

LOCAL NOTES

Australia: *Sydney: Street Lighting.*—Mr. H. R. Forbes Mackay has prepared a report upon the electric lighting of those streets in the city at present lighted by gas. The estimated cost is put at £26,100, whilst the revenue will amount to £10,718 on the basis of £23 per annum for each arc and £3 7s. 6d. for each incandescent lamp. Mr. Forbes Mackay has also calculated that whereas the cost per candle power per annum for gas lighting is 2s. 4d., the cost of electric lighting for those lamps at present in use is only 4·8d. The *Australian Mining Standard*, in giving these figures, suggests a demonstration of street lighting, before the Electricity Committee finally decides.

Melbourne: Tramways.—According to the *Australian Mining Standard*, the Government have appointed a Royal Commission to inquire into the whole question of suburban traffic in Melbourne. This foreshadows considerable extensions of tramways.

Ballymoney: *Overhead Wires.*—The promoters of the electric lighting scheme have asked for the Council's permission to erect overhead wires.

Bavaria: *Electricity Supply Statistics.*—The preliminary results of the Government inquiry relative to electrical generating stations in Bavaria show that 1,620 are owned by private individuals, 374 belong to companies, while about 500 are controlled by the Government, by municipalities, and by co-operative societies. The output of all these stations, including also the installations used only for private purposes, amounts to 275,472 kilowatts. About 47 per cent. of the plant is driven by steam, 30 per cent. is worked by water power and steam, and 8 per cent. is operated by water power only.

Brighton: *The Brighton-Worthing Tramways.*—The Corporation, at a special meeting on Friday, decided to oppose the proposal for the construction of tramways from Brighton to Worthing, so far as the consents of the Corporation are required.

British Columbia: *Reported Amalgamation.*—It is officially announced that the statement to the effect that the British Columbia Electric Railway Co. has entered into negotiations with the Western Canada Power Co. for the purchase of that undertaking has not the slightest foundation, and that no agreement has been made or considered either to purchase the property or take power from this undertaking.

Canada: *Train Lighting.*—The Canadian Pacific Railway Co. are adopting the Stone system of electric lighting on their new sleeping, dining and parlour carriages now being constructed at their Montreal works.

Chicago: *Municipal Exhibition.*—H.M. Consul-General at Chicago, says the *Board of Trade Journal*, reports that an International Municipal Congress and Exhibition will be held in Chicago from September 18th to 30th. The exhibits will be limited to manufactures, &c., required in connection with municipal government, including lighting, traction, telephones, &c. Some further particulars may be obtained at 73 Basinghall Street, London, E.C.

Chichester: *Street Lighting.*—Street electric lighting was inaugurated last week with very satisfactory results.

Dorchester: *Electric Lighting.*—The proposal of an Exeter firm to promote an electric lighting undertaking in Dorchester has been abandoned, as the preliminary enquiries have satisfied them that at present there is no prospect of making such a scheme successful.

Elland: *Tramways.*—The Council are still negotiating with Halifax for a tramway service, but their offer of £100 a year for five years as an inducement to the Corporation is considered inadequate in Halifax. A suggestion by the latter Corporation to accept a 1d. rate for 10 years, which would be equivalent to about £2,000, has been rejected. The matter rests here for the present.

Frome: *Electricity Transfer.*—Two of the largest consumers upon the electricity mains have petitioned the Board of Trade to withhold their sanction to the proposed transfer of the Electricity Works to Messrs. Edmundsons Electricity Corporation until a full inquiry has been held.

Johannesburg: *Tramway Service.*—The City Electrical Engineer has reported upon the increased and accelerated tramcar service, together with a general reorganisation of the management, which it is anticipated will bring about a saving of £7,000.

Leicester: *Working of Electricity Undertaking.*—Mr. James Swinburne's recommendations to amalgamate the two undertakings of the Electricity Department have been adopted by the Corporation. The proposal involves running the Aylestone alternating current power station virtually as a spare, and to give the bulk of the supply from the direct current station. An exhaust steam turbine set has recently been added to the latter. Mr. Swinburne puts on one side the possibility of scrapping one station absolutely, and recommends putting down motor generators at the direct current station coupled by trunk mains with the A.C. station.

Lewes: *Public Lighting.*—The Lewes and District Electric Supply Co., Ltd., are to be allowed to erect some street lighting standards, and to give an experimental demonstration of public electric lighting.

Malvern: *Trolley Omnibuses.*—The Council have decided to oppose the bill of the company, which proposes to run trolley omnibuses in Malvern.

Manchester: *Tramwaymen's Hours.*—The request of the tramwaymen for a universal eight-hour day has been refused by the City Council on the ground that this will involve an extra cost of £23,000 per annum.

Trolley Omnibuses.—It is anticipated that the Tramways Committee will have a trolley 'bus in service in a few months' time.

Position of Gas and Electricity Committees.—The Management of the Gas and Electricity Departments is still a matter of some discussion in Manchester, owing to the competition that is taking place between the two. The Lord Mayor is shortly to entertain the two Committees at an informal conference to deal with the matter. The complaint is made that whereas the Electricity Department is allowed to utilise, at any rate a portion of its profits in reducing the charge to consumers, the Gas Committee are definitely called upon each year to contribute £60,000 to the relief of rates.

Northumberland: *Tramways.*—A tramway scheme is proposed for linking up Blyth, Bedlington, Ashington, and Newbiggen.

Pontefract: *Electric Lighting.*—The Council have decided to lease their electric lighting Order to the Wakefield and District Light Railway Co.

South Shields: *Street Lighting.*—The offer of the Electricity Committee to provide 12 standards each containing three 100 c.p. metal filament lamps at £6 3s. 3d. per standard per annum, and to reduce the cost of the present 94 arc lamps from £22 10s. to £21 each per annum, has been accepted by the Corporation.

Wigan: *Tramways Renewals.*—In their report the elective auditors comment upon the provision made by the Tramways Committee for renewals, and recommend that in addition, if necessary, to meet each annual loss out of the district rate, provision should be made for a further sum of £5,000 annually, part of which should be utilised for working capital, and the remainder placed to renewals fund.

Worthing: *Tramways and Trolley Omnibuses.*—The Council have decided to oppose the two schemes for running tramways and trolley omnibuses in Worthing.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Australia.—Tenders are invited by the Postmaster-General's Department, 51 Spring Street, Melbourne, by March 14th, for the erection of wireless telegraph stations on Thursday Island and on the coast of Papua. Forms of tender can be seen at 72 Victoria Street, or 73 Basinghall Street, London.

Barnes.—Tenders are invited by the Electricity Committee for (1) straight tube water-tube boiler fitted for machine stoking; (2) 600–750 kw. dynamo; (3) surface condenser, motor-driven air and circulating pumps, river work and piping. Particulars from the Electrical Engineer. (See an advertisement on another page.)

Blandford.—A company has placed a proposal before the Town Council for an electric lighting scheme.

Burnley.—The Borough Electrical Engineer has recommended considerable extensions to the generating plant, and estimates are to be prepared for a 1,000 kw. generating set.

Cheltenham.—A new motor generator is to be installed, at an estimated cost of £1,285.

Halifax.—Extensions at the Electricity Works are to be

Hosted by Google

made at an estimated cost of £7,954. It is intended to instal a steam turbine plant. The Committee proposed to repay the capital in 10 years, but the Council resolved that the new plant shall be paid for out of revenue.

Hull.—The proposals of the Lighting Committee to spend about £100,000 upon electrical extensions (see ELECTRICAL ENGINEERING, December 29th, p. 827) have been adopted by the Corporation.

Kendal.—A 1,000 kw. steam engine and dynamo, switchboard panel, and other extensions are contemplated, at £1,450.

London: *Hackney.*—An expenditure of £545 is recommended upon replacing the coal conveyor chain and altering the position of the bunker, and providing a tramway and turntable.

Peterborough.—A loan of £2,000 is to be taken up for economisers, superheaters, and mains.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

GREATER LONDON.

Rebuilding of Wimbledon Hospital.

Girls' School, Higham Hill, Walthamstow.

Mess-room for nurses at North-Western Fever Hospital, Hampstead.

PROVINCES.

Annfield Plain.—Tenders are invited by January 23rd for the electrical installation at the electric theatre. L. H. Armour, 16 West Street, Gateshead.

Birkenhead.—Masonic Hall in Brook Street.

Birmingham.—New public baths.

Cardiff.—Kitchener Road Council Schools. Specifications by City Electrical Engineer.

Carnarvon.—Institute. Architect, R. Lloyd Janes, 14 Market Street.

Chatham.—Rebuilding Theatre of Varieties.

Cleckheaton.—Buildings for Temperance Society.

Devonport.—Extension of Post Office. H.M. Office of Works, Storey's Gate, London.

Eastbourne.—Proposed new workhouse.

Folkestone.—Theatre in Tontine Street.

Hastings.—Workhouse buildings.

Hereford.—New Art Gallery, etc.

Holyhead.—New church hall.

Larne.—New school.

Llandudno.—Extension of Gogarth Abbey Hotel.

Macclesfield.—Branch of Manchester & County Bank, Ltd.

Newmarket.—Technical school building. Architect, C. H. Waithman.

Stockport.—New police buildings.

Wakefield.—New school in Lawefield Lane.

Wallasey.—New Town Hall.

Wigan.—New Council School, Beechhill.

Winchester.—New school.

York.—New stores. York Equitable Industrial Society, Ltd. Architect, H. B. Beck, 28 High Street, Doncaster.

MISCELLANEOUS

Argentine.—The Department of the Interior propose to spend about £122,000 on telegraph and cable extensions, says the *Board of Trade Journal.*

Australia.—The Deputy Postmaster-General at Melbourne requires a branching multiple magneto lamp-signal switchboard and accessories. Tenders by March 7th.

The Deputy Postmaster-General at Perth invite tenders by April 18th for the supply of a common battery switchboard and accessories. Copies of the specifications, &c., in both cases can be seen at 72 Victoria Street, London.

The Deputy Postmaster-General, Melbourne, invites tenders by February 21st for 29 miles of lead-covered, paper-insulated telephone cable. Specification forms, &c., can be had from 72 Victoria Street, S.W., or 73 Basinghall Street, London, E.C.

The New South Wales State Railways Administration require two electrically-worked elevators for the tramway repair shops, Randwick. As the tenders are required by January 30th, this intimation is, therefore, only of use to those firms having agents in Australia, who can be instructed by cable.

Tender forms have been received at 72 Victoria Street, London, for (1) motor generators and accumulators, and (2) 10,000 telephone protectors. Tenders for (a) by February 28th, and (b) by March 3rd.

Tender forms in connection with the supply of 29 miles of telegraph cable can be obtained at 72 Victoria Street, London. Tenders by February 21st.

Bexley.—A fresh supply of meters is required, and the Lighting Committee recommend that they be purchased out of revenue.

Bournemouth.—The Tramway Manager recommends the borrowing of £4,640 for fitting certain improvements in the braking arrangements on the cars.

Leicester.—The Tramways Committee have decided to fit 19 additional cars with canopy tops, at an estimated cost of £102 each.

London: *Battersea.*—Tenders will shortly be invited for the supply of general stores for the Electricity Department, including arc lamp carbons, meters, cables, Nernst lamps, joint boxes, incandescent lamps, etc.

Islington.—Tenders are invited by February 3rd for general stores, including arc lamp carbons and globes, transformers and accessories, meters, cables, lamps, arc lamp parts, network boxes, etc. Particulars from Borough Electrical Engineer.

South Africa.—The Klerksdorp Council have taken up a loan of £7,500 for an electric lighting scheme.

Switzerland.—According to the *Board of Trade Journal*, the Zurich-Oerlikon-Seebach Electric Tramway Co. have been granted permission to extend their lines from Oerlikon to Affoltern, near Zurich, and from Schwamendingen to Dübendorf, a total length of 10 miles. The estimated cost is £29,640.

TENDERS RECEIVED AND ACCEPTED

Argentine.—The firm of Messrs. José Bernasconi and Co. have received an order for the electrical installation in the building now in course of erection intended as a residence for the President of the Republic. The cost is estimated at about £25,800.

Bournemouth.—The following firms tendered for the reconstruction to the overhead system of the different tramways in Bournemouth:—Messrs. Clough, Smith & Co.; the British Insulated and Helsby Cables, Ltd.; and W. Griffiths & Co. The lowest tender, namely, that of Messrs. Clough, Smith and Co., at £1,726, was accepted.

Halifax.—The Electricity Committee have accepted the following tender of the British Thomson-Houston Co., Ltd.:—1,500 kw. steam turbo-generator, £3,073; Worthington condenser, £1,216; two 750-kw. rotary converters, £2,091.

London: *County Council.*—Messrs. Siemens Bros. Dynamo Works, Ltd., have obtained the contract for the supply of metal filament lamps for the ensuing twelve months to the Stores Department and also to the L.C.C. Asylums Board.

Stepney.—The tender of Messrs. Reavell & Co., Ltd., at £245, has been accepted for a motor-driven air-compressor at the Blyth's Wharf power station.

Sheffield.—The tender of the British Electric Transformer Co., Ltd., for transformers and choking coils at £872, and for six sets of transformers with series gear at £211 per set, has been accepted.

The tender of Messrs. Wellerman Bros. has been accepted for extensions to the buildings at the Neepsend power-house at £14,700.

Whitby.—Then tender of Mr. G. Booth for the installation of electric light in the Guardians' Board Room at £13 17s. has been accepted.

Wireless Telegraph Notes.—It is expected that the new wireless telegraph station at Scarborough will be completed before next spring.

It is stated that naval officers are visiting the southern portion of Ceylon to select a site for a wireless telegraph station. An agitation for a wireless telegraph station in Ceylon has been going on for more than five years.

It is stated that M. Farman has successfully carried out some preliminary experiments with wireless apparatus fitted on an aeroplane at the Buc Aerodrome, Paris. Messages are said to have been transmitted over a distance of ten kilometres.

The Italian Government have confirmed a law made last year decreeing that all immigrant ships trading with Italian ports must be equipped with Marconi wireless telegraph apparatus. The specified range of the equipment is put at 300 km., and the wave length at 600 metres.

It is stated that the North German Lloyd and the Hamburg-America shipping companies will not renew their contracts with Marconi's Wireless Telegraph Co., which expire shortly, but will, in accordance with the desires of the German Government, adopt the Telefunken system.

OSRAM·LAMPS

Hosted by Google

APPOINTMENTS AND PERSONAL NOTES

The late Mr. Gustav Byng, Chairman of the General Electrical Co., Ltd., left estate valued £100,700.

The recommendation to increase the salary of Mr. R. Foster, Borough Electrical Engineer at Aston, from £500 to £600 per annum has been sanctioned by the Council.

Mr. J. McMillan, Borough Electrical Engineer at Falkirk, has resigned. We understand that it is Mr. McMillan's intention to go abroad.

Mr. P. W. Freudemacher, formerly in the sales department of Messrs. Crompton and Co., Ltd., has started business on his own account, under the style of P. F. Williams and Co., at 34 Bargery Road, Catford, S.E. The new firm is specialising in the manufacture and installation of organ-blowing plant.

An assistant junior demonstrator at a salary of £80 per annum is required at the Northampton Institute. (See an advertisement on another page.)

Mr. W. S. Wilson has resigned his position as outside manager of the electrical department of Messrs. Clarke, Chapman & Co., Ltd., to take up the position of branch manager for Messrs. Johnson & Phillips, Ltd., at 44B Blackett Street, Newcastle-on-Tyne. Telephone No.: Central 1691. By an error in our last issue we stated that Mr. Wilson was joining Messrs. Pinchin, Johnson & Co., Ltd., instead of Messrs. Johnson & Phillips, Ltd.

Pending Electrical Lawsuits.—The Cause List for the Hilary Sittings, which commenced on Wednesday, contains very few actions of electrical interest. There is the patent action by the Marconi Company against the British Radio-Telegraph and Telephone Company, before Mr. Justice Parker, who will also have to deal with a petition for an extension of time of a patent No. 11,575 of 1897 granted to Sir Oliver Lodge. This patent relates to a system of wireless telegraphy in which the receiving apparatus is syntonised, and resonates in response to a sufficiently prolonged series of waves of definite frequency, and covers various arrangements of the oscillatory circuits. Sir John Benn is appealing against the verdict of Mr. Justice Ridley, who awarded £8,000 damages against him for libel in respect of the G.B. system in the Mile End Road, and a new trial is also asked for. The Divisional Court will have to deal with certain points of difference which have arisen between the British Westinghouse Electrical and Manufacturing Co. and the Underground Electric Railways Company of London, and there are a few actions for injuries on the London electric railways and tramways.

L.C.C. Westminster Technical Institute.—A special course of lectures on "Illumination," by Mr. J. S. Dow, will be given on Fridays at 7.30 p.m., commencing to-morrow. Fee for the course, 2s. 6d.

Calendars.—We have received an office calendar, with changeable date cards for each day of the month, from the Atlas Metal & Alloys Co., Ltd., 52 Queen Victoria Street, E.C.

The Bowesfield Steel Co., Ltd. (110 Cannon Street, E.C.), are sending to their friends, with their New Year's greetings, a combined blotting-pad and diary of convenient form.

The Central London Railway have kindly sent us one of their desk calendars, in which the paper strip containing the dates is wound on rollers, so that one month appears through the window at a time.

The calendar being issued by Ferranti, Ltd., is a very neat production on a fumed oak base, and bears an illustration of one of the company's non-metallic motor starters.

The Electrical Standardising, Testing, and Training Institution.—Among the special lectures for this term at Faraday House are the following:—Dr. W. H. Eccles began a course of lectures on "Wireless Telegraphy and Telephony," and Mr. A. B. Clark, of Lot's Road generating station, gave the first of his demonstrations on "Fuel Testing" to the senior students of Faraday House this week. In connection with the commercial training of the students at Faraday House inaugurated by a lecture on "Depreciation" by Major O'Meara (Engineer-in-Chief to the Post Office), Mr. A. Schneider (Managing Director, Evershed & Vignoles, Ltd.), has given a lecture on "Works Management," and Mr. Robert Hammond will shortly deliver a series of lectures on "Electricity Undertakings."

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £58 10s. to £58 15s. per ton (last week, £58 15s. to £59).

A meeting of the Davey Electric Co., Ltd., will be held on January 31st at 3 p.m., at the office of Mr. J. Andrews, 20 North John Street, Liverpool, to hear the liquidator's account of the winding-up.

D.P. Battery Company.—Messrs. Pemberton and Clark, of Colmore Row, Birmingham, have been appointed the company's Midland agents in place of Mr. J. Hilton, the latter having joined the staff of Messrs. Bruce Peebles and Co., and will look after their interests in the Midland district.

Belfast Electrical Exhibition.—Messrs. Siemens Brothers and Co., Ltd., have an attractive stand at this exhibition, where their well-known O.S. wiring system with "Stannos" fittings was exemplified. Fittings with tantalum and one-watt lamps were shown, as well as heating apparatus, cables, fuses, batteries, etc., and a fine display of holophane glassware.

Branch Office.—The British Thomson-Houston Co., Ltd., have opened a branch office at Castle Buildings, Swansea. The telephone No. is 123 Central, and the telegraphic address "Asteroidal, Swansea."

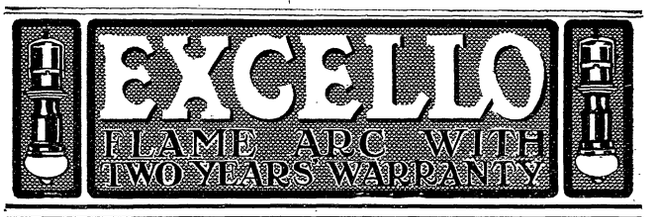
Bankruptcies.—The last day for receiving proofs in the bankruptcy of A. J. Hollington, electrical engineer, late of 37 Walbrook, London, is January 21st. The Official Receiver is Mr. G. W. Chapman, Bankruptcy Buildings, Carey Street, London.

The trustee in the bankruptcy of R. E. Joy has been released.

Agency.—Messrs. Feld Bros. & Co., Ltd., 25 Budge Row, London, E.C., have taken over the sole agency for Great Britain and the Colonies for Messrs. Brenne, Hangarter and Co., Haspe, Westfalia, for permanent magnets.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Mexico Tramways Co.—A quarterly dividend of 1¼ per cent.



Mexican Light & Power Co.—A quarterly dividend of 1 per cent.

Rio de Janeiro Tramway, Light & Power Co.—This company is issuing further capital to the extent of 23,750 shares of £25 each, in order to provide funds mainly in connection with the extension of works in Rio.

Dublin United Tramways Co.—Dividends at the rate of 6 per cent. per annum on both the preference and ordinary shares are recommended, after setting aside £12,000 to renewals.

Prosecution of Telephone Engineers in Antwerp.—In May last year, four telephone engineers were placed on trial at Antwerp on the charge of stealing trade secrets and documents belonging to the Bell Telephone Co. on their leaving that firm to take up engagements with the General Electric Co., Ltd. The evidence occupied the Court from May 27th to May 29th, but early in June the accused were acquitted. Last week the Bell Telephone Co. appealed against the verdict, but the Appeal Court has confirmed the acquittal.

Electrical Exhibition at Belfast.—An electrical exhibition was opened by the Belfast Electricity Department on Monday. A prominent feature is an "electric house," fully equipped with electric lighting, heating, and cooking apparatus, and electrically-driven laundry machinery. A number of well-known electrical firms have separate stands, among whom may be mentioned the British Thomson-Houston Co., the Electric & Ordnance Accessories Co., Ferranti, Ltd., the General Electric Co., Ozonair, Ltd., Purcell & Nobbs, Simplex Conduits, Ltd., Wright & Wood, and Siemens Brothers & Co.

SUMMARY

A Special Literary Supplement is included in this issue, containing notices and reviews of books, and a carefully revised list of selected works on electrical engineering and allied subjects.

The stage and general lighting arrangements of the Palladium Variety Theatre are described. Tantalum lamps are mainly employed, and some fine special electrolier fittings are installed. For dimming the lamps of the stage floats, &c., a new pattern of metallic resistance regulator is used. (Page 29.)

Illustrations are given of some new turbo-alternator sets recently supplied by Messrs. Dick, Kerr and Co. (Page 31.)

A new electrically-driven van, with a four-wheel drive, has recently been brought out. (Page 31.)

A specially protected telephone set for use in proximity to high tension transmission lines is described on page 31.

The Marconi and Telefunken interests in the German mercantile marine have been combined by the formation of a new German company, which will hold the rights of either system as regards German shipping, and install both Marconi and Telefunken apparatus. (Page 32.)

In connection with the substitution of Parsons for Westinghouse turbines at the Lot's Road power house of the Underground Electric Railways Co. of London, Ltd., the High Court has decided that the Westinghouse Company must pay to the Underground Co. the cost of the difference in steam consumption between the guaranteed and actual figures obtained whilst the Westinghouse machines were at work, plus the cost of installing the Parsons turbines. (Page 32.)

The hearing of the action by the Marconi Co. against the British Radio Telegraph & Telephone Co. for alleged infringement of the Marconi 1900 patent continues. The defendants argue that the patent does not cover the use of a coreless auto-transformer as employed by them, as it was not known in 1900. Further, they hold that there was no subject matter for the patent, as tuning was inevitable in the transformer arrangement of Braun's 1899 patent. (Page 33.)

Among the specifications published by the Patent Office on Thursday last was one by Bruce Peebles and Co. for a machine which can be used as a double-current D.C. generator, a rotary converter giving two D.C. voltages, a D.C. transformer, or a constant-current generator. F. Broadbent covers an automatic motor starter for push-button control with some novel features. Special damping grids for preventing the flashing over of rotary converters on excessive overload are described by Miles Walker. A lamp-holder locking device for use in existing lamp-holders, devised by H. Brooker and W. A. Hooper, is also described. A patent by the Westinghouse Brake Co. for the electrical control of mechanically interlocked railway signals and points expires on Thursday next, after the full life of fourteen years. (Page 34.)

Hosted by Google

AT a recent meeting of the Glasgow Local Section of the Institution of Electrical Engineers, Mr. W. W. Lackie gave a short address dealing with the advantages of electric heating, ventilation, and power. (Page 35.)

THE Greenock Corporation have been informed that all their electric lighting profits must go to reserve.—The St. Pancras Electric Lighting Committee have objected to certain criticisms in a local paper.—A dispute has arisen between the Manchester Tramways Department and their employees, whose Association have asked for arbitration.—The Rhyl Borough Electrical Engineer reports considerable reduction in works cost by the use of a Diesel engine.—The legality of allowing 50 per cent. discounts at Sheffield has been questioned. (Page 35.)

SPECIFICATIONS are being prepared in connection with a large electric power scheme in Bombay. The Calcutta Electric Supply Corporation require sub-station switchboards; the Hammersmith Council a 3,000 kw turbo-alternator, E.H.T. and L.T. distributors; a mixed pressure turbo-alternator is required by the Oldham Corporation; and electric lighting apparatus at Turton. The Bacup Corporation require high and low tension cables; West Ham Corporation, electrical accessories; and Bournemouth and Sheffield Corporations, tramway stores. A supply of arc lamp carbons is required by the Antwerp Corporation. (Page 36.)

THE Musselburgh & District Electric Light & Traction Co. are issuing new capital, and the Sao Paulo Tramway, Light & Power Co. invite subscriptions for £300,000 five per cent. debenture stock. (Page 37.)

"Pay as You Enter" Tramways.—It is stated that "pay as you enter" tramways, which are used to some extent in America, will shortly make their appearance upon a London tramway system.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JANUARY 19TH.

Rugby Engineering Society.

8 p.m. At Benn Buildings, High Street. "Electric Power in Collieries," by J. Miller.

FRIDAY, JANUARY 20TH.

Institution of Mechanical Engineers.

8 p.m. At Storey's Gate, Westminster. "Modern Electrical Dock Equipment, with Special Reference to Electrically Operated Coal Hoists," by W. Dixon and G. H. Baxter.

TUESDAY, JANUARY 24TH.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. At Municipal School of Technology. "Switchboard Measuring Instruments," by H. T. Warner.

WEDNESDAY, JANUARY 25TH.

Dynamicables.

7.30 p.m. Dinner at Trocadero.

THURSDAY, JANUARY 26TH.

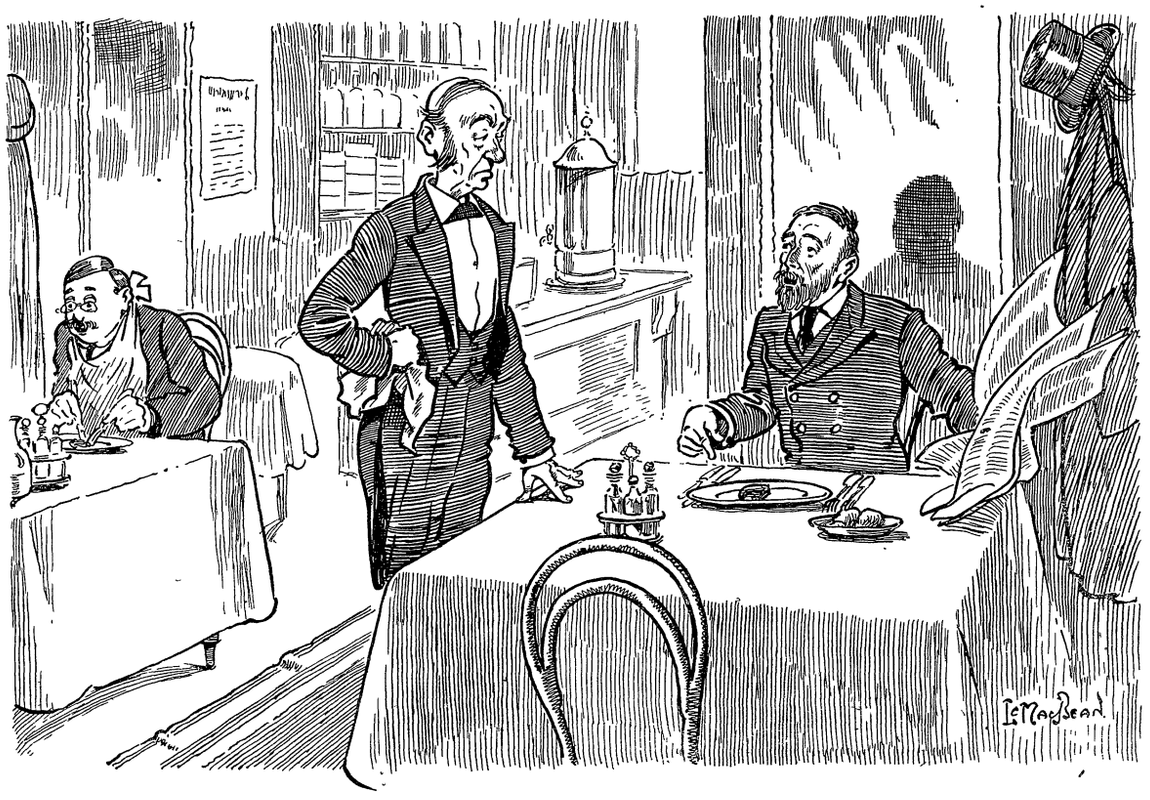
Institution of Electrical Engineers.

8 p.m. At Victoria Embankment. (1) "Modern Long-distance Transmission of Electrical Energy," by W. T. Taylor. (2) "Extra High Pressure Transmission Lines," by R. Borlase Matthews and C. T. Wilkinson.

FRIDAY, JANUARY 27TH.

Physical Society.

5 p.m. At University College, Gower Street, London. Agenda:—(1) "A Demonstration of Phase Difference between the Primary and Secondary Currents of a Transformer by Means of a Simple Apparatus," by Prof. F. T. Trouton, F.R.S. (2) "A Note on the Experimental Measurement of the High-frequency Resistance of Wires," by Prof. J. A. Fleming, F.R.S. (3) "The Measurement of Energy Losses in Condensers Traversed by High-frequency Oscillations," by Prof. J. A. Fleming, F.R.S., and G. B. Dyke.



Royal Institution.

9 p.m. Evening Discourse by Prof. W. H. Bragg, F.R.S., on "Radioactivity as a Kinetic Theory of a Fourth State of Matter."

SATURDAY, JANUARY 28TH.

Association of Mining Electrical Engineers.

6.30 p.m. *Lancs., &c., Branch.* At Grand Hotel, Manchester. Address by President, Mr. W. Maurice, and discussion on Mr. E. K. Scott's Paper, "Electricity in New South Wales Coalfields."

CRITICAL DINER (who has been reading a report of Mr. Lackie's recent discourse at Glasgow): I'm thinking that ninepence is verra expensive for this wee bit meat. Ye wad na hae gi'en more than 4¾d. for it at the flesher's, and the heid of the electricity depairtment o' the great City of Glasgow says that the cooking is one-thir-r-d of a far-r-thing. Y'r weages should be a'most a neegative quantity, y'r stand-by losses are sma', and I dinna expect to peay lar-r-ge estaiblishment char-r-ges.

Hosted by Google

"ELECTRICAL ENGINEERING"

LITERARY SUPPLEMENT

REVIEWS OF BOOKS

Encyclopædia of Municipal and Sanitary Engineering. Edited by W. H. Maxwell and J. T. Brown. 561 pp. 10¼ ins. by 7½ ins. Many illustrations. (London: Constable & Co.) 42s. net; by post to British Colonies, 43s. 8d.

THOSE who are interested in local administration must long have felt the need of a book of this character. Borough councillors cannot be expected to possess a thorough general knowledge of the numerous branches of municipal and sanitary engineering which are carried out under their authority, and, although they must necessarily be guided by their professional advisers and officials, yet, as a help to the proper understanding of these gentlemen's reports, the value of a superficial acquaintance with the various subjects, or, failing this, of a sound book of reference, cannot be over-estimated. The volume before us provides such a reference book in the convenient "dictionary" form. Its print, and most of the illustrations, are clear and good, and in general the treatment of the subjects is the correct one for the purpose—neither too "popular" nor too technical.

The sections dealing with water supply, and with sewage disposal, and other branches of sanitary engineering are excellent, but those relating both to electrical engineering and gas engineering could have been improved upon considerably. It is true that the main article on electricity is interesting and practical—it could hardly be otherwise from the pen of Mr. H. M. Hobart—but it leaves untouched some of the most important matters to the municipal councillor. Nothing at all is said with regard to the mains, and the whole question of the statutory powers and obligations of a municipality owning electricity works is neglected. This is rather the fault of the editors than of the author, and we are at a loss to apportion the blame for the incorrect footlines to two out of the six poor illustrations, but Mr. Hobart must take responsibility for the term "megakelvin." We can picture the face of a borough electrical engineer who is suddenly asked by his chairman the number of his yearly megakelvins. On the other hand, the general description of the equipment of generating stations and the functions of the more important parts of the plant, given in Mr. Hobart's article, is excellent, and its value is enhanced by frequent numerical examples. The article on tramways, which is very poor stuff, is evidently by another writer.

The Foundations of Alternate-current Theory. By C. V. Drysdale. 300 pp. 8¾ by 5¾ in. 190 illustrations. (London: Edward Arnold.) 8s. 6d. net; abroad 8s. 9d.

STUDENTS who find it difficult to form a mental picture of what is taking place in alternating-current problems will welcome this volume. The author explains, in a clear and convincing manner, all the effects of the various combinations of resistance, inductance, and capacity in alternating-current circuits, with the aid of mechanical models and familiar illustrations of the analogous results of friction, inertia, and elasticity in everyday life. Physical conceptions of the phenomena of electrical working are invaluable for a proper understanding of the problems which arise, and mechanical analogies are of undoubted help in elementary work. On the other hand, we believe that the advanced student's imaginative powers are sufficient to enable him to form mental pictures of electrical and magnetic phenomena independent of mechanical ideas, and that the author's extension of mechanical analogies to problems of mutual induction, transformers, and polyphase currents is unnecessary.

Steam Turbines: Their Design and Construction. By Rankin Kennedy. 101 pp. 8½ in. by 5½ in. 62 figs. (London: Whittaker & Co.) 4s. 6d. net; abroad, 4s. 9d.

THERE is no attempt in this book at competition with the larger standard works on the subject, but it is designed for the use of engineers and students who desire to obtain an insight into the methods whereby the principal dimensions of steam turbines are calculated, referring to first principles. The work is, therefore, more of an introduction to the correct point of view of looking at steam turbine problems than a treatise on design—as might, perhaps, be inferred from its title—and as such it is clear and straightforward.

The Deinhardt-Schlomann Series of Technical Dictionaries in Six Languages. Vol. X.: Motor Vehicles. 996 pp. 6¾ ins. by 4 ins. Numerous illustrations. (London: Constable & Co., Ltd.) 12s. net; abroad, 12s. 8d.

THIS volume of the now well-known series of technical dictionaries is arranged in the same way as the previous volumes on other branches of engineering, that is to say, the ideas are arranged according to subject matter with the German, English, and French expressions on one side of the page, and the Russian, Italian, and Spanish on the other, while suitable illustrations are given in the central space. The latter part of the book consists of alphabetical indices with the Russian words separately, owing to the difference in alphabet. The greater part of the volume does not, of course, concern electrical engineers, but there is a considerable section devoted to electric cars with the extraordinary title "Engine Equipment of Electromobiles." Motor-boats as well as motor-cars are dealt with, and the latter part of the book is devoted to airships and aeroplanes. The production is under the official auspices of the Royal Automobile Club of Great Britain and Ireland, and the cover bears their badge. This would lead one to expect an accuracy and correctness which, we are sorry to say, is wanting, for when we examine the work in detail we find numerous proofs that the revisers were not acquainted with the expressions in common use in England. We should have thought that every member of the Expert and Technical Committee of the Club, which professes to have revised the proofs, would have known, for example, that the words "monoplane" and "biplane" are always used in this country for what are here described as "single-deck aeroplanes" and "double-deck aeroplanes." Again, a front glass on a motor-car is never spoken of as a "window." In spite of its imperfections, however, the work is wonderfully complete, and in the absence of a better should be of considerable use.

Exercises in Electrical Engineering. By Prof. T. Mather and G. W. O. Howe. 71 pp. 7½ in. by 5 in. 22 figures. (London: Edward Arnold.) 1s. 6d. net.; by post in U.K. or abroad, 1s. 8d.

THIS is a collection of questions set in the second-year exercise classes and examinations at the Central Technical College. They will afford an excellent test for the student to ascertain whether his knowledge of the various subjects is up to a proper standard, and the answers at the end of the book to the numerical examples will enable him to check the correctness of his replies. The book will also be invaluable to teachers.

Water Turbine Plant. By Jens Orten-Böving. 197 pp. 11½ in. by 9 in. 216 illustrations. (London: Raithby, Lawrence Co.) 10s. 6d.; by post, U.K. 11s., abroad 11s. 9d.

THE author of this work, which is correctly described on the title-page as a short practical treatise, is too well known in connection with water-power schemes and the design of hydraulic plant to need any introduction. The book is intended to be partly a text-book on water turbines, and partly as a sort of catalogue of types, sizes, and dimensions of a particular series of designs. Its interest is also enhanced by a collection of brief descriptions, with excellent illustrations, showing the general arrangement of numerous hydro-electric installations in various parts of the world. We understand that the basis of the text-book portion of the volume is the material of a series

Machine Sketches and Designs for Engineering Students.
By A. CRUICKSHANK, A.M.I.Mech.E., and R. F. MCKAY, M.Sc. 4to. 1s. 6d.

LONDON: EDWARD ARNOLD, 41 & 43, MADDOX ST., W.

of lectures given by Mr. Böving before the Japanese Association of Mechanical Engineers. There are many curves, tables, and figures which should be of great use to those studying water-power schemes. The information is clearly put and practical, and represents the practice which is the outcome of extensive experience in the rapidly increasing water-power installations in the author's native country, Sweden.

The Journal of the Municipal School of Technology, Manchester. Vol. III. 392 pp. 9¾ in. by 7¼ in. Many figures and plates. (Manchester: Municipal School of Technology.)

IN this large volume are included a number of reprints and abstracts of Papers which have been published by various technical societies, &c., embodying original research and contributions to technical literature by members of the teaching staff and students of the school.

Mechanical World Pocket Diary and Year Book for 1911. 330 pp. 6 ins. by 4 ins. Numerous figures. (Manchester: Emmott & Co.) 6d. net; by post in U.K., or abroad, 8½d.

FOR the last three years purely electrical subjects have not been dealt with in the "Mechanical World Year Book," but have been reserved for a companion work. The mechanical volume has, however, had added to it more than was taken away to form the electrical pocket book, and this, the twenty-fourth annual issue, is further enlarged. On the other hand, revision in the form of condensation of old matter has also taken place. Among the sections which have been extended are those on high-speed cutting tools, gearing, hardening, &c., of steel, details of gas engines, and an explanatory introduction to the tables of logarithms has been included. The dimensions of a true pocket book have not been exceeded, and a wonderful amount of information is given for the money.

"Mechanical World" Electrical Pocket Book for 1911. 208 pp. 6 in. by 4 in. 100 figs. (Manchester: Emmott & Co.) 6d. net; by post in United Kingdom or abroad, 7½d.

THIS wonderful sixpennyworth, which is a companion volume to the *Mechanical World* pocket diary, has been considerably revised since last year's issue, and tables, &c., have been added relating to current densities, temperature rise and losses of machines, illumination, and incandescent lamps. The sections on accumulators, circuit breakers, electricity in mines, and boosters have also been re-written. The whole appears to be clearly written, concise, and up to date, but we would suggest that a little more information regarding modern metal filament lamps might have been included with advantage.

Fowler's Mechanics' and Machinists' Pocket Book, 1911. 460 pp. 6 in. by 4 in., numerous figures. (Manchester: Scientific Publishing Co.) 6d. net; by post, 8d.

THIS handy little volume, which is now in its third edition, contains a mass of information and practical rules for draughtsmen, foundrymen, pattern makers, fitters, &c. Chapters are included on machine-tool design, shop practice, wheel gearing, belt and rope drive, materials used in engineering, &c., with numbers, tables, and illustrations. Some tables from the Engineering Standards Committee's reports dealing with bolts, nuts, spanners, screw threads, and running fits, are included in this edition.

The "Practical Engineer" Pocket Book and Diary, 1911 (703 pp), and **The "Practical Engineer" Electrical Pocket Book and Diary, 1911** (567 pp). 3½ in. by 5½ in. Many figures. (London: Technical Publishing Co.) 1s. 6d. net; by post, 1s. 9d.

BOTH of these are still true pocket books, although the number of pages in the larger one is somewhat increased since last year's issue. There has also been considerable revision of the electrical volume, which includes articles on dynamo design, &c., by Mr. C. C. Hawkins. New matter appears on the Ilgner and other power equaliser systems, but it is a pity such antiquated information is allowed to remain as the statement that the Osmium lamp has not yet reached the commercial stage, in the otherwise fairly up-to-date section on metal filament lamps.

The Electrical Engineers' Diary, 1911. 11 in. by 6½ in. (London: S. Davis & Co.) 2s. 6d.; abroad, 3s.

IN addition to being a diary, this book contains a considerable amount of information of a useful character relating to various applications of electricity for factory driving, lighting, cooking, heating, &c., with figures of cost. There is also a list of London streets in which electric supply mains are laid, together with particulars of the various supply authorities.

NEW PUBLICATIONS

We shall be pleased to send any of the undermentioned works to addresses in the United Kingdom, at the net prices quoted. The price for sending to the Colonies and abroad is also quoted when there is an increase. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203–6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

"Electric Motors." By F. B. Crocker and M. Arendt. (London: Crosby, Lockwood & Son.) 10s. 6d. net; abroad 12s. 2d.

"Fowler's Mechanics' and Machinists' Pocket Book," 1911. 460 pp., 6 in. by 4 in., numerous figures. (Manchester: Scientific Publishing Co.) 6d. net; by post 8d.

The "Practical Engineer" Electrical Pocket Book and Diary, 1911. 567 pp., 3½ in. by 5½ in., many figures. (London: Technical Publishing Co.) 1s. 6d. net; by post, 1s. 8½d.

The "Practical Engineer" Pocket Book and Diary, 1911. 703 pp., 3½ in. by 5½ in., many figures. (London: Technical Publishing Co.) 1s. 6d. net; by post, 1s. 9d.

The Practical Electrician's Pocket Book and Diary, 1911. 363 pp., 5¼ in. by 3½ in., many figures. (London: Rentell and Co.) Cloth, 1s. net; by post, 1s. 2d. Leather, 1s. 6d. net; by post, 1s. 8d.

ELECTRIC LIGHTING OF THE PALLADIUM

THE electrical equipment of the Palladium, London's latest variety theatre, includes several features of particular interest. Holophane lighting is employed to a large extent; a new pattern of dimming switch with metallic resistances is used; the lamps are all metal-filament, mostly Tantalum, and some very fine fittings, especially designed for the purpose, are installed. The contractors for the whole of the electrical equipment were Siemens Brothers Dynamo Works, Ltd., of London, who sublet the wiring work to Rashleigh, Phipps & Co., of Oxford Street, London.

The supply is taken from the three-wire 220-volt mains of the St. James' & Pall Mall Electric Light Co. A pressure of 110 volts is employed for all the lighting, and of 220 volts for the motors, fans, &c. Special mains are brought into the back of the building for the stage lighting, and into the front of the building for the house lighting. A small alternative supply is also provided for the house lighting by the London Electric Supply Corporation, in accordance with the rules of the London County Council, and alternate fittings in some parts of the auditorium are wired off this supply.

The stage equipment comprises a stage switchboard, regulator and dimmer, a "special effect" switchboard, stage lift, and the stage fittings. The latter consist of seven battens 52 ft. long, each with 250 32-c.p. Tantalum lamps of three colours, 250 footlights, "hanging lengths," "bunch lights," and "proscenium lights." Altogether over 2,400 incandescent lamps of three different colours are in use on the stage. In addition, there are 18 arc lamp projectors, 9 being on the stage and 9 in the auditorium.

The equipment in the house comprises the house switchboards, an electrically-driven "Vortex" suction cleaner plant, and electric fans. The fittings were designed by Messrs. Siemens Brothers Dynamo Works to correspond with the decorations of the building, and are of the Georgian type. The auditorium is lighted from the roof by means of two 50-light electroliers, each 12 ft. high and 9 ft. in diameter, one of which is illustrated in Fig. 1. All the shades of these fittings are of the Holophane type. The large Holophane bowls at the foot contain 100-c.p. "One-watt" drawn tungsten filament lamps. There are, of course, a large number of other smaller fittings in the auditorium. The electric direction and other signs about the building are of the Cloisonnée pattern, with the lettering set out in coloured glass beads. The exterior of the building is illuminated by 22 flame arc lamps. The total number of incandescent lamps in the whole building is close on 4,000, and altogether the lighting and power represents over 400 h.p. The building is wired with Siemens vulcanised india-rubber wires ranging from 3/22 to 37/14, drawn into enamelled steel conduits. "Stannos" wiring is used in the dressing-rooms and elsewhere. Upwards of 30 miles of wire and about 8 miles of conduit were used.

The main supply cables for the stage lighting consist of two lead-covered, armoured cables, each 0·8 sq. in., and one of 0·4 sq. in. section. Four lead-covered, armoured cables of 0·5 sq. in., and two of 0·25 sq. in. section lead from the meter room to the stage switchboard, forming two 110-volt circuits on each side of the three-wire system, and one 220-volt circuit for the fans and other motors. The stage switchboard, illustrated in Fig. 2, is probably the largest of its kind that has yet been installed in this country. It controls lamps taking a total of 2,100 amperes at 110 volts. In order to comply with the regulations of the London County Council, all connections have been arranged on the front of the board, and this has necessitated a somewhat special design so as to accommodate the larger number of cable thimbles, &c. The board is divided into four horizontal sections, two on each side of the three-wire system, and the circuits are approximately balanced on two sides of the system. The circuits are grouped into four sections, viz., stage lighting through dimmers, general stage lighting, stage arc lamps, and those

FIG. 1.—LARGE ELECTROLIER IN AUDITORIUM.

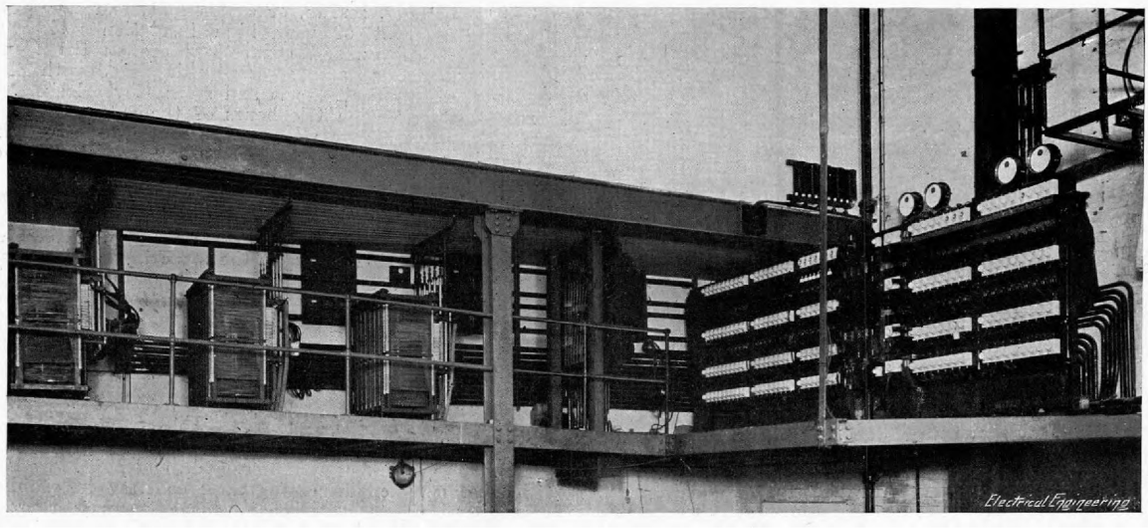

FIG. 2.—STAGE SWITCHBOARD, DIMMER RESISTANCES, ETC.

C

Hosted by Google

auditorium lights which are controlled from the stage. An additional panel carries the "black out" switches by means of which nearly all the stage lights can be switched on or off simultaneously for scenic effects. About 90 circuits are provided for, and each is fitted with double-pole "Zed" fuses and a single-pole knife switch. A slate panel with circular orifices, in which a stock of spare cartridges is kept ready, is provided.

The regulation of the stage lighting in respect of colour, dimming, and illumination is effected by the stage regulator or dimmer, the most important part of a theatre installation. This is shown in Fig. 2, while the operating levers are shown in Fig. 3. This regulator differs in construction from those usually employed, in that metal resistances are used in place of liquid resistances. These resistances are placed in series with the various groups of lamps, and owing to the very fine subdivision of the resistances, the light may be reduced gradually without visible steps from the full candle power of the lamps until they are completely dark. The adjustment is effected by means of regulating discs, all the lamps of one colour in each fitting being controlled by one of these discs. The discs are rotated by means of levers, and each is constructed in the form of a pulley, over which a cord, held in tension by a counter-

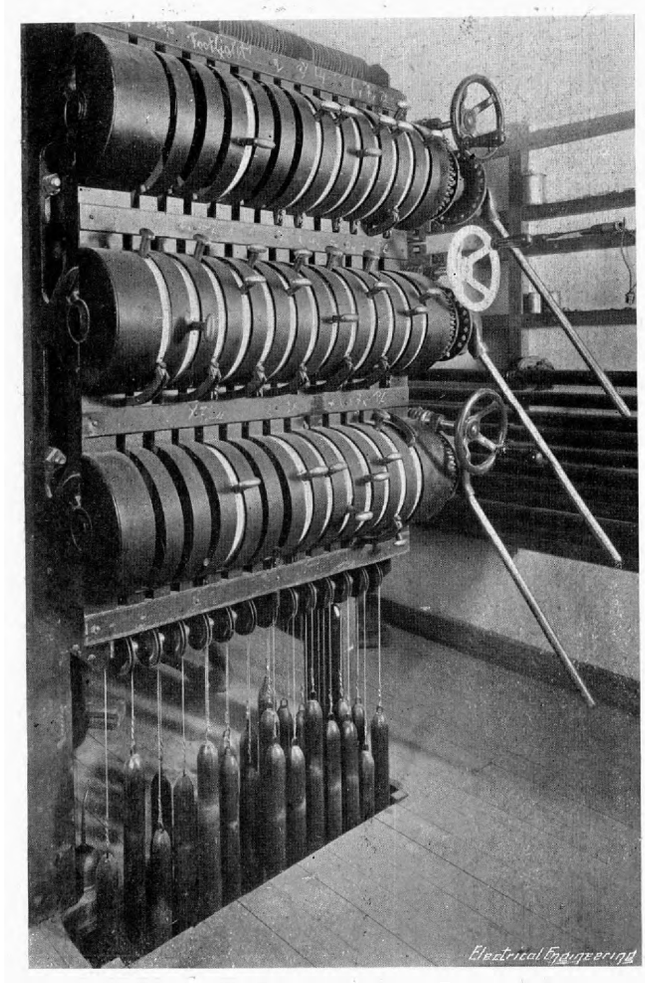

FIG. 3.—DIMMER CONTROL BOARD.

weight, leads to the sliding contacts of the corresponding resistance. An automatic tappet switch cuts out the contact brushes when all resistance is cut out. All discs for the same colour are mounted in one row, and any number of them may be coupled together on to a common spindle in their rear. The coupling device connects the separate regulating levers with the common spindle, so that by turning the single hand-wheel situated at the side, uniform movement of any or all the coupled levers is obtained, and any desired groups of lamps of one colour may be brightened or dimmed simultaneously. The hand-wheels can also be fitted with a fine regulation in order to obtain a slow and steady movement of all the coupled levers. The discs are provided with scales and pointers, which permit of reading off the light intensity at any moment. The total current arranged for on this regulator is 1,140 amperes; it has 33 regulating discs, arranged in three rows of 11 discs each. A switchboard for special lighting effects is situated at the back of the stage, for providing lights for properties and effects introduced by the various "turns," as required.

In order to provide a raised platform for scenic effects, and to facilitate the removal of scenery and properties to the basement, a portion of the stage floor, measuring approximately 20 ft. by 10 ft., and supported by ironwork capable of sustaining a load of 20 tons, is arranged as an electrically-driven lift, which is operated by a Siemens motor. The latter with its gear is capable of raising the lift with a load of 30 cwt. The control is of the Eastman semi-automatic push-button type, with separate push-buttons for the up and down journeys. The lift comes to a standstill immediately the push-button is released, and, therefore, permits of obtaining very correct adjustment of level. A suction cleaning service is installed in the auditorium, saloons, corridors, &c. This consists of a Siemens "Vortex" suction cleaner fixed in a basement underneath the stalls, and connected to a system of air pipes, which run to eleven connection points distributed throughout the house. The machine is direct-coupled to a 5-h.p. 220-volt D.-C. motor. About 500 ft. of 2-in. and 1½in. steel piping are run in the body of the walls, &c., and serve nickel-plated connection pieces fixed on the surface of the plaster or in sunk boxes. Flexible hose in lengths of 16 ft. can be connected to any of these points so as to reach all seats, carpets, &c., and a number of nozzles of various shapes are supplied, which can be readily connected to the flexible hose by simple airtight conical plug and socket joints.

The leads for the batten lights are connected through the dimmers to multiple stage plugs fixed on the flyrail. Similar plugs are mounted on the battens. Lengths of flexible multiple connecting cables connect the battens to the flyrails, and enable the battens to be disconnected easily when it is required to raise or lower them. These cables are fitted with plug sockets at each end, and at the points of connection are laid in grooves formed in the handle portion of the socket and strongly bound round with leather. The plugs are fitted with a locking attachment to prevent accidental disconnection. A number of "Lightning" arc lamps are provided, one being fixed on each batten length, at the right and left ends alternately of the battens. These lamps are connected to a multiple way switch of the rotating type, and when the handle is moved round rapidly the lamps are switched on in rapid succession for the fraction of a second only, whereby a forked "lightning" effect is produced. The projector lamps are very powerful, and are similar to those employed for marine work. The larger projectors, of which three are in use in the biograph room at the back of the roof, and two in the projector room in the centre of the roof, take a current of 45 amperes each. The small lamps which are fixed at the sides of the proscenium and on the stage perches, as well as the portable ones, take 35 amperes each

The switchboard situated in the front part of the building is similar in design to the stage switchboard, and consists of three sets of panels controlling the general lighting, exterior arc lamps, and that portion of the auditorium lights not controlled by the stage switchboard, but which have to be "blacked out" for certain "turns." Fifty-four circuits are provided for, each of which is fitted with double-pole "Zed" fuses, and a single-pole knife switch. A smaller switchboard connected to the alternative supply is mounted alongside. There are 14 "Typhoon" fans about 50 in. diameter, mounted on the ceilings under the balconies, for assisting in the ventilation of the auditorium, and a number of table fans are provided for the saloons, &c. The whole of the wiring on the stage and in the auditorium is controlled from some 60 teak and iron distribution boxes. These have "Zed" fuses and switches fixed on enamelled slate panels in such a manner that the back is free from drilling, screws, or connections, and this has resulted in the attainment of very high insulation resistance. All terminals, 'bus-bars, and connections are on the front of the slate, and the cases are asbestos-lined, glazed with plate glass, and fitted with circuit labels and strong lever locks.

Inter-communication telephones of the automatic replacement line selector type give all offices, boxes, stage, &c., the means of communication without the intermediation of an operator. A central battery switchboard system connects all boxes with the bar, and also with each other. Calling and clearing signals are given simply by lifting the telephone from the automatic hook switch, and replacing it after close of conversation. A loud-speaking system connects the stage manager's office and the Royal Box with the stage, and permits of directions being given to the assembled artists on the stage by the stage manager, who may be seated in his office or watching a rehearsal or performance from the Royal Box. The receivers were found to be too loud, and the circuits have been choked so as to give only a small proportion of the usual effect.

We are indebted to Siemens Bros. & Co., Ltd., and Siemens Bros. Dynamo Works, Ltd., for the information contained in this article, and to Mr. Walter Gibbons, managing director of the London Theatre of Varieties, Ltd., and Mr. F. J. Humphrey, the supervising engineer, for their courtesy in enabling us to view the complete installation. Some Siemens' representatives conducted a party of friends connected with the electrical Press round the building on Friday last, and afterwards entertained their guests to dinner.

New Telegraph Cable between England and Norway.—This cable, which was described in our last issue, was manufactured and laid for the Post Office by Messrs. Siemens Bros. & Co., Ltd.

A DICK, KERR MIXED-PRESSURE TURBO-ALTERNATOR

THE accompanying illustrations show two views of 500-kw. mixed-pressure steam turbines supplied by Messrs. Dick, Kerr and Co., Ltd. (Preston), to a colliery in Scotland. The sets, which are driven by turbines of the impulse type (Bergmann system), are designed to give 500 kw. at 3,000 r.p.m., with exhaust steam at 16 lbs. per sq. in. absolute, or with dry saturated live steam at 90 lbs. per sq. in., or with a combination of both pressures, and to give their full output when working condensing with a vacuum

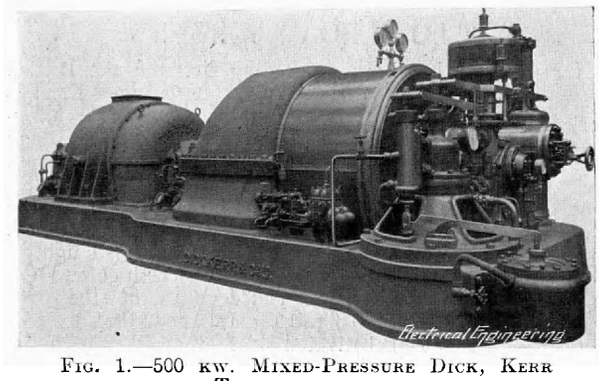

FIG. 1.—500 KW. MIXED-PRESSURE DICK, KERR TURBO-ALTERNATOR.

of 27·5 in. They are capable, under any of these conditions of steam pressure, of giving an overload of 25 per cent. for two hours, and 100 per cent. for five minutes. Each turbine is mounted on a combination base, and is complete with two bearings, and direct-connected to its alternator through a flexible coupling. The turbines are provided with high-pressure and low-pressure main stop-valves, high-pressure steam separator, governor, steam and oil gauge pipes, emergency device for stopping turbine when normal speed is exceeded by 10 per cent. (this safety device closing the main turbine stop-valve and not the throttle-valve), oil receptable with filter, direct-connected oil pump, separate steam oil pump for flooding the bearings before starting up, speed

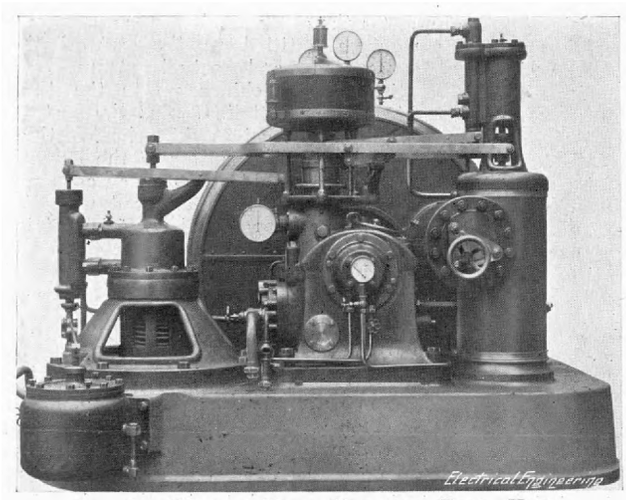

FIG. 2.—500 KW. MIXED-PRESSURE DICK, KERR TURBINE, SHOWING GOVERNOR, &C.

adjusting device, &c. The governor is extremely sensitive, and is based on a principle which allows steam to enter into the turbine in a continuous and steady flow, whether running on mixed-pressure or on live steam, or when changing from one to the other.

The alternators are designed to give 625 k.v.a. (500 kw. at 80 per cent. power factor), at 3,000 volts, and 50 cycles, and the temperature rise does not exceed 70° F. above an air temperature of 77° F., after an eight hours' run at full load.

The Polytechnic.—The fund for rebuilding the Polytechnic, Regent Street, as a memorial to King Edward VII., to which £20,000 has been contributed by the London County Council, and some £50,000 has been subscribed privately, is being kept open till Easter, as many persons who have been identified with the institution may wish to take part in the scheme.

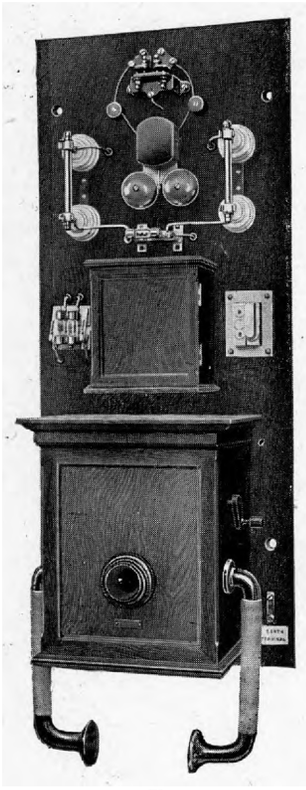
A NEW ELECTRICALLY-PROPELLED VAN

IN view of the efforts that are being made at least by one enterprising supply authority to popularise electric vehicles, the new van illustrated here, which the India-Rubber, Gutta-Percha, & Telegraph Works Co., Ltd. (Silvertown), have just produced, is of considerable interest. The principal peculiarity which distinguishes it from most others is the system of four-wheel drive by two motors geared respectively to live front and rear axles, with differential gear, and, in case of the front axle, with special steering joints. This four-wheel, which has been thoroughly tested on passenger vehicles of the type described in ELECTRICAL ENGINEERING, Vol. III., p. 580, is found to give a better tractive effort, and greatly to diminish side slip. The weight of the particular vehicle illustrated is about 32 cwt., and of the battery with a crate, 13 cwt. The

SILVERTOWN ELECTRIC VAN.

battery consists of 38 KyA 14 type Tudor cells of 210 amp.-hour capacity at the 42-ampere rate, and is arranged so that it can be released from the chassis by turning a key on the front cross member of the frame, and so releasing the four supporting bolts. The controller provides for connection of the motors in series or parallel, and a switch is provided by which either motor can be cut out, and the vehicle driven by the other alone.

We understand that the company are prepared to build vans for special work to suit purchasers' requirements; to erect charging plant complete for any number of cars to work from existing electricity supply, or from a self-contained generating set: to fit up garages complete with battery charging plant, and necessaries for proper maintenance of battery and car, and to work out systems of maintenance and running generally to suit special conditions.



The Tramways & Light Railways Association.—Commencing with the January number, the official circular now becomes the *Journal* of the Tramways & Light Railways Association. This number contains a detailed list of Tramway Bills, or Bills containing provisions relating to tramways, deposited in Parliament in the current Session; an article on rail wear (illustrated), by a member of the Association; matters relating to the Association, and the annual list of members. It is announced that the annual dinner and smoking concert will be held during the month of February, if possible on Friday, the 17th.

Institution of Electrical Engineers.—The following is the list of candidates for election at the meeting on Thursday:—Associate Members:—J. S. Burgis, J. E. Grant, T. H. Haigh, P. G. Hay, J. A. Hunt, E. Lack, W. F. Marshall, J. W. Wyles. Students: T. H. Andrew, H. H. Bagnall, E. A. Beavis, H. C. Burrowes, F. Carr, P. V. Chari, E. J. Chawner, S. N. Chopra, G. C. Clark, W. E. Clark, L. E. Cooke, H. S. Craig, A. J. Dannhorn, J. A. Donald, E. T. Driver, M. Enver, A. Furtado, H. J. Gwyther, C. L. Hall, L. E. Harris, N. F. Hecht, G. Henderson, C. J. Hews, P. R. Hughes, H. Humphreys, E. Hutchison, H. Y. V. Jackson, S. C. Jarrett, B. M. Kazalbash, R. Lewis, A. Lisle, G. K. Loveday, L. A. McDougald, E. G. Mabbs, J. B. Malpass, R. R. Mann, E. L. Mathias, A. A. Maytham, E. R. A TELEPHONE FOR USE ON HIGH-TENSION CIRCUITS

THERE are many cases where it is convenient to run telephone lines on the same poles as or near to high-tension transmission lines, and special precautions must be taken to avoid danger to the users of the instruments in case of accidental contact between the high-tension circuit and the telephone wires. To meet such cases, Messrs. Siemens Brothers & Co., Ltd. (Caxton House, Westminster), have brought out the special equipment illustrated here. The telephone is so arranged that the user is not brought into contact with any current-carrying part, the sound being transmitted by means of insulated tubes. The lines enter at a point lightning arrester and then pass through two retardation coils for preventing residual discharge, and continue through two H.-T. non-arcing fuses which cut off the apparatus in case of a cross with a power circuit. A vacuum arrester bridged across these fuses serves to short-circuit the instrument in the event of a difference of potential arising between the lines. Each line then traverses a combined spark gap and vacuum arrester fitted with a heat coil. These arresters will actuate at 300 volts, and thus afford protection against every power circuit. The heat coil is arranged to fuse at 0·3 ampere, thereby protecting the instrument from "sneak" currents.

SIEMENS TELEPHONE FOR USE ON HIGH-TENSION CIRCUITS.

AMALGAMATION OF THE MARCONI AND TELEFUNKEN INTERESTS IN GERMANY

AN important agreement was concluded on Saturday last between the Compagnie de Télégraphie sans Fil of Brussels, the licensees of the Marconi patents in Germany, and the Gesellschaft für Drahtlose Telegraphie of Berlin, the owners of the Telefunken system, together with the Allgemeine Elektricitäts Gesellschaft, Siemens & Halske A.-G., and the Braun-Siemens Gesellschaft, by which the interests of all the above in wireless telegraphy for the German mercantile marine have been transferred to a new company, the Deutsche Betriebs-Gesellschaft für Drahtlose Telegraphie, m.b.H. The directors of this new company are Herr Mamroth, director of the Allgemeine Elektricitäts Gesellschaft; Mr. G. Marconi; Col. Thys, director of the Banque d'Outremer, Brussels; Dr. Franke, director of Siemens & Halske A.-G.; M. Travailleur, director of the Compagnie de Télégraphie sans Fils; and Count G. d'Arco, director of the Telefunken Co.

We have ascertained that this agreement relates to the German mercantile marine only, and will not affect the remaining business of either the Marconi Co. or the Telefunken Co. The new company will equip German merchant ships with apparatus of either the Marconi or the Telefunken pattern according to the desire of the shipowners, and whatever the system, the apparatus will be known under the name of "Debeg" (the telegraphic address of the new company). From the results of the litigation regarding the Lepel patent, referred to on page 22 of our issue of January 12th, it would seem that the use of the present Telefunken system might involve difficulties as regards patents, and, consequently, the more extended adoption of the Marconi system seems probable. The exact significance of the refusal of the Telefunken patent has not yet been made known, and further developments will be awaited with interest. It will be of particular interest to see which system the German Government will finally adopt for the Post Office and naval stations.

With regard to the statement that the North German Lloyd and Hamburg-Amerika shipping companies are being persuaded by the German Government to adopt the Telefunken system on the expiry of their contracts with the Marconi Co., we are informed officially by the Marconi Co. that this is wholly incorrect, and that there is every reason to believe that the original Marconi apparatus will be retained. A similar denial is being issued by the Telefunken Co. We understand that there are about 45 Marconi installations distributed amongst the ships of the larger German shipping companies, while the Telefunken Co. have installed equipments on some 40 smaller vessels.

THE LOT'S ROAD TURBINES

AN arbitration has been proceeding between the British Westinghouse Co. and the Underground Electric Railways Co. of London with regard to the eight Westinghouse turbines, which were installed at the Lot's Road power-house between 1902 and 1906. These turbines from the commencement never came up to the contract figures for steam consumption, and although in 1907 one of the machines was taken away by the makers and reconstructed, yet it was found impossible to give the guaranteed figures. Consequently it was agreed between the Westinghouse Co. and the Underground Co., in consequence of the very superior steam consumption figures guaranteed, that Parsons turbines should be substituted for the Westinghouse machines. Then arose the question of how much the Westinghouse Co. should be paid for their machines on the one hand, and the amount of compensation which the Westinghouse Co. should pay the Railway Co. on the other hand. The matter was referred to the Hon. Alfred Littleton, K.C., M.P., but he found himself in some difficulty in determining the principle, and referred the matter to the Courts for a decision. The matter was dealt with on Thursday by a Divisional Court consisting of the Lord Chief Justice and Mr. Justice Hamilton and Mr. Justice Avory. On the one hand, there was a question as to whether the commercial life of the Westinghouse machines should be determined and the difference between the guaranteed consumption and the actual steam consumption over this long period ascertained and converted into a money value. This obviously would have involved a very considerable sum, and the Underground Co. did not wish to assert their rights upon this basis of reckoning. On the other hand, the Underground Co. claimed that they were entitled to the cost of the difference in the guaranteed and actual steam consumptions of the Westinghouse machines up to the time that the Parsons machines were installed, plus the cost of installing the Parsons machines. Against this, the Westinghouse Co. claimed that, as by the installation of the Parsons machines the Underground Co. were able to effect an economy in working which they would never have achieved with the Westinghouse guaranteed figures, they could not fairly claim for the cost of the Parsons machines, and that in effect the Westinghouse turbines had become obsolete at the time of installing the more efficient Parsons machines. It was claimed on their behalf that, having in mind the very considerable difference between the best steam consumption which the Westinghouse Co. had hoped to get, and the steam consumption guaranteed by the Parsons machines, any business concern would have scrapped the Westinghouse machines immediately, as the extra capital cost of the Parsons machines would have been quickly repaid by their greater economy in working. The Lord Chief Justice, in giving judgment, which was agreed to by the other two judges, held that the Underground Co. were entitled to the cost of installing the Parsons machines, plus the difference between the actual and guaranteed steam consumptions of the Westinghouse machines, whilst they were at work. On this basis, the Underground Co. will pay the remainder of the contract price of £250,000 for the original eight Westinghouse machines, but the matter has to go back to the arbitrator for decision as to the amount of compensation.

Rubber Trades Exhibition.—An international rubber and allied trades exhibition is to be held at the Royal Agricultural Hall from June 24th to July 11th next. A number of trophies, medals, and other prizes will be awarded, and arrangements have been made for several rubber-producing countries to exhibit officially through their Governments. An international congress will be held in connection with the exhibition. Full particulars can be obtained from the organising manager, Mr. A. Staines Manders, 75 Chancery Lane, W.C.

"ELECTRICAL ENGINEERING" LIST OF SELECTED TECHNICAL BOOKS.

We shall be pleased to send any of the following books to addresses in the United Kingdon at the *net* published prices named, unless otherwise stated. The increased price for sending abroad is also quoted after each book. All the books listed have been recommended by our editorial staff and reviewers.

Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-206 Temple Chambers, Temple Avenue, E.C., and should be accompanied by a remittance.

Electricity Supply and Distribution.

THE WIRELESS TELEGRAPH PATENT CASE

THE hearing of the action between Marconi's Wireless Telegraph Co. and the British Radio Telegraph & Telephone Co. was resumed in Mr. Justice Parker's Court on Wednesday of last week. A report of the proceedings previous to the Christmas recess was given in ELECTRICAL ENGINEERING, December 15th and 22nd. On Wednesday, Mr. Terrell concluded his opening speech for the defendants, his main argument being that the Marconi 1900 patent in question was invalid, as it was merely a combination of the transformer circuit described in Braun's 1899 patent with what was common knowledge in 1900 as regards tuning. Given the Braun specification at that date, an electrical engineer would, he said, have used a Tesla coil, and would have tuned. Mr. Justice Parker pointed out that in Braun the aerial was not shown as earthed, that no mention was made of tuning or loose coupling, which was essential to tuning, but Mr. Terrell argued that a reference to the "well-known vertical sending wire" implied an earthed aerial, that the only suitable transformer, the Tesla, had a loose coupling, and that tuning between the two circuits was inevitable. With regard to infringement, he held that the auto-transformer without an iron core was not known in 1900, and, therefore, the Marconi patent did not cover it. If it could be proved that it was known, then the patent still did not cover it, as it should have been included in the patent as a known alternative to a two-coil transformer.

Mr. W. Duddell, F.R.S., in giving evidence, said that Marconi's specification referred only to two-coil Tesla transformers; at that date the only one-coil device which would have been suitable for the purpose was called an Oudin resonator. At that time, the word auto-transformer was only applied to devices with iron cores. To carry out Braun's arrangement in 1900, he would have used a Tesla transformer and would have tuned the two circuits, although there was no mention of tuning in the specification. Braun introduced a large capacity in his oscillatory circuit, and was thus enabled, for a given amount of energy, to use a short spark and a larger current with less damping so as to produce a longer train of waves. Mr. Astbury, however, argued that the sole object of Braun was to produce a lower frequency of oscillation, and that a statement in the specification as to avoiding damping meant only such damping as would entirely prevent oscillations taking place. Mr. Duddell stated that the mutual induction in the defendants' apparatus only amounted to a few per cent. and was not needed. Apart from this, it had been argued that the inductance acted as a one-to-one auto-transformer, but, in his opinion, an inductance shunted across a circuit in that manner only took a magnetising current, and gave no transformer action whatever. In connection with the question of infringement, Mr. Colefax drew attention to the fact that in books by Zenick and other authorities, a metallic connection of the aerial with the inductance of the oscillatory circuit was called a Braun direct coupling, while when a transformer was used, it was called a Marconi inductive coupling.

Prof. E. W. Marchant was then examined as to the meaning of the words transformer and auto-transformer, and the defendants then called Prof. C. B. Boys, F.R.S., who admitted, on cross-examination, that Braun did not refer in his specification to any benefit to be obtained by the use of a transformer. Mr. Justice Parker suggested that Braun only wished to increase the voltage in the aerial, and said that, in his opinion, there was no indication of tuning in the specification. He thought that Braun wished to force the oscillations of the closed circuit on to a plain aerial, and did not think of building up the oscillations in a tuned aerial circuit as Marconi did. Mr. N. Maskelyne then gave evidence on behalf of the defendants, stating that, given Braun in 1900, he would certainly have used a Tesla coil, which had a loose coupling and would have tuned.

At this point, as the result of a complaint by Mr. Astbury that too many experts were being called by the defendants, Mr. Justice Parker said that Mr. Maskelyne must be the last, and, consequently, the defendants were unable to call Prof. Silvanus Thompson. Permission was given, however, to call three witnesses on certain points. Mr. W. H. Patchell was examined on the meaning of the word transformer in 1900, and Mr. R. S. Wright (Newton & Co.) and Mr. L. B. Miller gave evidence as to having adjusted the circuits of Tesla coils by varying the number of turns and the capacity previous to 1900. Mr. Astbury recalled two experts for the Marconi Co. to give evidence on certain new points which had arisen, and Mr. Colefax then commenced summing up for the defendants.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

SWITCHES.—A card from Siemens Brothers' Dynamo Works, Ltd., gives illustrations and prices of single throw, quick break knife switches with knee type handles, from 15 to 1,000 amperes.

BED WARMERS.—An electric bed warmer, provided with a heating element which can easily be renewed, is described in a leaflet from Messrs. Frampton & Paine (29 Old Queen Street, S.W.).

CALENDAR.—The wall calendar being issued by the Jandus Arc Lamp & Electric Co., Ltd., is an artistic production, with a most effective reproduction of a pencil study of a head.

ELECTRIC BRAKING CONTROLLERS.—A leaflet from the Allgemeine Elektricitäts Gesellschaft of Berlin describes the main features of several types of controllers for cranes and hoists, with positions in which electric braking is effected by causing the D.C. motor to act as a dynamo, the energy being dissipated in suitable resistances.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

CORONATION ILLUMINATIONS.—The price list of electrical illumination devices for the Coronation, which has just been issued by the General Electric Co., is a magnificent production. Besides detailed price lists of selected switches, enclosed fuses, junction boxes, connectors, wall plugs, adaptors, lampholders, ceiling roses, cables, &c., there are numerous pages attractively printed in colours showing a complete range of illuminated devices from the simplest to those of most ambitious nature. Another special feature is the information regarding the company's "Pixielite strip," which is particularly well adapted to this sort of work. A number of types of sign flasher are also included, and a complete code for ordering enhances the utility of the list. The company ask us to state that both application for copies of this list and orders from it should be made early to avoid disappointment. There is no doubt that the trouble the General Electric Co. have taken in these preparations will result in opportunities for a great deal of business to the trade, and will assist in making the displays at the time of the Coronation a fine advertisement for electricity.

ANSWERS TO CORRESPONDENTS

Correspondents must in all cases send their names and addresses with their queries, and, if they do not desire the reply to be published after their own name, should add a "nom de plume." Questions should be addressed to the Editor, ELECTRICAL ENGINEERING, *203-6 Temple Chambers, Temple Avenue, London, E.C. The Editor will not guarantee to answer all questions in this column, and the enclosure of a stamped and addressed envelope is therefore desirable. Books recommended will be forwarded on receipt of a remittance for the amount mentioned.*

W. J. W.—Diversity factor is the ratio of the sum of the consumers' maximum demands to the maximum demand on the station. The method of calculating the load factor customarily employed is to multiply the units *sold* during the year by 100, and to divide by the maximum demand on the station, multiplied by the number of hours in a year. The number of units is arrived at from the books of the undertaking (*i.e.*, the total registered by the consumers' meters), and the maximum demand on the station from the switchboard log-book. The maximum demand should be taken as that supplied to the feeders.

J. PERREN.—In addition to the information given last week, a Bill has been deposited for the next session of Parliament by the Metropolitan Electric Supply Co. for the purchase of the Acton Council's electricity undertaking for a sum of £5,000, plus the capital charges on the outstanding capital. This is the result of a resolution by the Council to part with the undertaking because it was not successful.

Electrical Propulsion of Ships.—A note appeared on page 23 of our issue of last week to the effect that a patent had been granted to the British Thomson-Houston Co. for a system of electrical propulsion of ships in spite of opposition. Mr. W. P. Durtnall desired the insertion of a specific reference to his original patent for polyphase drive for ships, *i.e.*, No. 17,248 of 1905, or, if the Comptroller thought this unnecessary, a general disclaimer to "the use for propulsion purposes on a vehicle or boat of a combination comprising a prime mover, a polyphase generator having a stationary armature, and a polyphase motor." The Comptroller has granted the patent as already stated, but requires the following amendments:—(*a*) a reference in the specification that the invention relates to the propulsion of ships by plant of a known kind, and (*b*) the insertion in the complete specification of the words: "Neither do we claim generally for propulsion purposes the use in combination of a prime mover, a polyphase electric generator, and a polyphase electric motor."

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published January 12th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

24,137/09. **Rotary Transformer.** BRUCE PEEBLES & CO., LTD., and P. D. DE LA COUR. This machine has an armature wound for n poles, a $2n$-pole field, and $2n$ brushes, arranged in two sets connected to two external circuits. The magnet frame is split into two ring parts, each carrying half the number of poles excited by shunt windings across the two circuits respectively. The brushes are so arranged that the armature M.M.F.'s are in the same axes as the corresponding field M.M.F.'s, and two series compensating windings are provided, one in each circuit. The uses of the machine are as follows :—Rotary D.C. transformer; double-voltage D.C. generator; double D.C. voltage converter from A.C.; constant current motor-generator for welding, arc lighting, &c.; generator and transformer for battery or flywheel load equalising plant. Nineteen figures.

29,339/09. **Motor Starter.** F. BROADBENT (London). An automatic starter suitable for push-button control is described. On pressing a starting button, a solenoid pulls up the starter arm quickly to the position in which all resistance is in the armature circuit, and on reaching this position a tappet switch is closed and the main switch solenoid energised so that the armature circuit is closed. On releasing the starting button, the resistance arm falls slowly against the resistance of a dash-pot and the motor speeds up. Although the tappet switch is released, the main switch remains closed as the solenoid is energised by means of a bye-pass connection through the main switch contacts. To stop the motor, a second button is pushed, and this breaks the circuit of the main switch solenoid. Six figures.

29,411/09. **Heating System.** S. L. R. PRICE (Dublin). An electrical system for heating buildings consists in the use of a series of horizontal pipes connected at intervals to hollow uprights provided with adjustable openings. Pipes of smaller diameter are inserted in the horizontal pipes, and a heating resistance of asbestos-covered wire is wound in the annular space between. The heated air from the pipes flows into the room through the openings in the uprights. Five figures.

29,511/09. **Battery Plate Separators.** H. F. JOEL (Forest Gate). Separators for use between the plates of primary or secondary cells consist of a backing of perforated ebonite and a sheet of porous acid-proof fabric, such as woven asbestos, fixed together by binding strips and rings of celluloid. Five figures.

29,944/09. **Automatic Battery Switch.** L. SUNDERLAND and G. C. PILLINGER. This patent covers an automatic switch for starting up a petrol- or gas-engine driven set by motoring the dynamo, and for controlling automatically the charging of the battery. Four figures.

30,482/09. **Rotary Converters.** MILES WALKER. To enable rotary converters to withstand heavy overloads without flashing over, the pole-shoes are provided with damping rings or grids which surround the rear but not the leading pole tip. This enables a heavy armature current to neutralise almost completely the flux at the leading tip, while increased magnetisation of the rear tip is prevented and the induced voltage reduced. Two figures.

6,132/10. **Lamp-holder Locking Device.** H. BROOKER and W. A. HOOPER (London). This is a metal band provided with two vertical grooves to take the bayonet pins, and two spring catches pointing inwards. The band is placed over the lamp-cap and is slid over the holder until the catches slip over the bends of the bayonet slots. At the same time two detents on the band enter the slots. The lamp can be removed only by breaking the band with a pair of pliers. Four figures.

7,212/10. **H.-T. Insulators.** BRITISH THOMSON-HOUSTON CO., LTD. (*General Electric Co., U.S.A.*). An insulator for high pressures and to withstand severe mechanical stress consists of a cast-iron bell supporting the H.-T. wire and enclosing the head of a porcelain insulator. The insulator has a cavity into which enters the strain bolt. This is provided with a ball-retaining flange, and balls of copper or brass or of steel with an outer coating of a soft metal, are inserted between this flange and the insulator to distribute the mechanical pressure. Eight figures.

16,441/10. **Manufacture of Glass.** A. G. BLOXAM (*Siemens & Halske A.-G.*). This specification covers improvements on a process described in Patent No. 9,563 of 1908 for the manufacture of glass in an electric induction furnace. The walls of the furnace are constructed of a conducting mixture of silicon or graphite with fireclay. This heats up and melts the glass mixture, which then conducts, so that both direct and indirect heating is obtained.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: SIEMENS BROS. & CO., HIRD and BRADLEY [Twin projectors] 27,914/09; CARBONE ARC LAMP SYNDICATE (*Carbone*) [Method of enclosing the arc] 8,167/10; GEB. SIEMENS & CO. [Electrodes] 9,076/10.

Distributing Systems, Cables & Wires, Insulating Materials, &c.: WILLIAMS [Cables for burglar and fire alarm systems] 11,667/10; PETERSON [Manufacture of insulating material] 23,671/10.

Dynamos, Motors & Transformers: CROMPTON & CO., MACFARLANE and BURGE [Machines] 7,488/10; ALLGEMEINE ELEKTRICITÄTS GES. [Method of securing rotor to shaft] 15,293/10; DASSENOY [Synchronous motors] 23,174/10.

Electric Ignition: DELAGE and WOOG [Electric lighting of gas burners] 6,154/10; BAKER [Magnetos] 7,096/10; BERGMANN [Igniting devices] 10,260/10; R. BOSCH [Magnetos] 18,095/10.

Electrometallurgy & Electrochemistry: GADOMSKY [Extracting copper from ores] 3,965/10; REID [Induction furnaces] 9,459/10; ESTELLE [Depolarising agents for primary cells] 11,837/10; STANTON [Ozonising apparatus] 17,138/10.

Storage Batteries: FOX, LATTIN, and DRAKE & GORHAM, LTD. [Battery regulating switch mechanism] 1,843/10.

Switchgear, Fuses, and Fittings: CURTIS and ADAMS MANUFACTURING CO. [Controllers and starters] 30,566/09; ANSELL [Motor starters] 205/10; MURRAY [Switching mechanism] 16,152/10; ADAMS MANUFACTURING CO. (*Cutler Hammer Manufacturing Co., U.S.A.*) [Resistance controllers] 16,985/10.

Telephony and Telegraphy: BROWN [Telegraphy and telephony] 29,985/09; CORDES [Insulation of condensers for telephones] 30,548/09; JAHNKE and TATE [Wireless telephone transmitter] 1,518/10; KITSEE [Telegraphic relays] 2,348/10.

Traction: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Electric braking] 3,011/10; PRENTICE [Train control system] 7,621/10.

Miscellaneous: BARKER [Coal conveyers] 30,123/09; WILSON [Coal face conveyer] 30,127/09; KOOPMAN [Electric welding] 71/10; THOMSON [Magnetic devices for holding riveting tools] 81/10; ALDRICH [Burglar alarms] 3,527/10; LUCAS and EDWARDS [Electric sounding horns] 6,632/10; ARENS [Electric massage finger stalls] 17,061/10; PONTELEC WELDING PATENTS, LTD. [Manufacture of cans] 18,090/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Arc Lamps: SCHMIDT, 29,506/10.

Distribution Systems, &c.: PAUL [Overhead transmission system] 28,687/10.

Electric Ignition: R. BOSCH [Ignition of multi-cylinder engines] 19,241/10.

Electrochemistry, &c.: GES. FÜR CHEMISCHE INDUSTRIE IN BASLE [Electrolysis of fused alkali chlorides] 18,300/10; WILDERMAN [Electrolysis of alkaline salts] 26,568/10.

Heating: GEISSINGER [Automatic heat control] 29,463/10; ROCHE [Water heaters] 29,733/10.

Incandescent Lamps: ALLGEMEINES CHEMISCHES LABORATORIUM OSKAR H. ARENDT [Supports for metal filaments] 29,505/10.

Instruments: G. A. SCHULTZE [Resistance measuring arrangement] 29,465/10.

Miscellaneous: A.-G. BROWN, BOVERI ET CIE. [Safety device for thrust bearings] 15,370/10.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

2,094 of January 26th, 1897. **Railway Points and Signals.** WESTINGHOUSE BRAKE CO., LTD. (*J. G. L. Schreuder, U.S.A.*). This patent covers improvements in the signalling gear described in the previous specifications 2,443/91 and 24,702/95. The signals and points, which are operated by electric motors, are electrically controlled by switches mechanically interlocked so that when the switch and signal levers of a route have been moved, the levers of any opposing route are locked.

The following are the more important Patents that have become void through non-payment of renewal fees.

Dynamos, &c.: R. ROUGÉ and G. FAGET [Rotary converter] 5,561/00; J. H. MAWDSLEY [Brush-holders] 19,368/05.

Switchgear, &c.: W. P. THOMPSON (*T. von Zweigbergk, U.S.A.*) [Prevention of arcing at contacts of motor controllers] 22,250/97; C. H. OFFORD [Automatic time switch] 21,229/02.

Traction: P. M. LINCOLN [Automatic switch for trains running on both A.C. and D.C. systems] 20,001/04.

Hosted by Google

EVERYDAY USES OF ELECTRICITY

AT last Tuesday's meeting of the Glasgow Local Section of the Institution of Electrical Engineers, Mr. W. W. Lackie (Chief Electrical Engineer, Glasgow Corporation) gave a short address entitled "Notes on Everyday Uses of Electricity." The main reason for which he advocated the use of electricity for lighting was that it neither vitiated, exhausted, nor raised the temperature of the atmosphere and thus reduced the need for ventilation. As regards cost, electricity at 3d. per unit was about equivalent to gas at 2s. per thousand cubic feet on the basis of metal filament lamps and incandescent gas mantles.

Taking up the subject of ventilation, he pointed out the disadvantages of a coal or gas fire as a means of ventilation, as only the air in the lower part of the room was changed, and cold draughts across the floor were set up. The ideal method was to draw off the vitiated air at the ceiling, and he showed how much more efficient electric fans were than gas-jets for the purpose. Passing on to heating, Mr. Lackie showed that coal at 20s. per ton was equivalent to electric heating at 0·34d. per unit. Less than half the heat, however, would be required owing to the decreased necessity for air renewal, and taking into account also the superior way in which it was controlled and directed where required, it was evident that electricity at 1d. per unit would compare favourably with gas. Electric heating had great advantages where a uniform temperature had to be maintained in a sick room. He then summarised the results of the electric cooking demonstrations at the recent Smoke Abatement Exhibition in Glasgow, where, on the average, 1¾ lbs. of meat was cooked per unit. The difference in the efficiency of electric ovens was considerable. Four 7-oz. steaks were cooked in 14 minutes with a consumption of 0·35 units. One unit would, therefore, do twelve 7-oz. steaks or chops in 14 minutes. The heat required for potatoes and puddings was negligible, as they were done at the same time as the roasting. The reliability and steadiness of electric cooking was pointed out, and some figures of the time taken to perform various operations with particular pieces of apparatus were given. With regard to power, he desired to call attention particularly to the exaggerated statements made in some of the gas-engine manufacturers' catalogues, as to the comparative costs of electric power and the running of independent suction gas plants. Comparisons were made with actual records showing considerable discrepancy. It had not been sufficiently realised that an electric motor only takes energy in proportion to the work it is called upon to do, but that a suction gas plant does not vary its fuel consumption according to the demands made upon it.

DISCUSSION.

After some remarks by the chairman, Mr. Sam Mavor, Mr. PARSONS said that he did not agree that electricity at 0·34 pence per unit was equivalent to coal at 20s. per ton. He gave as an example of house heating figures relative to a small house of five rooms where the coal bill during the past six years averaged £6 11s. per annum, whereas with electricity at 1d. per unit this would be increased to £20. He would not advocate the use of electricity as a medium for ordinary heating until Mr. Ferranti's figure of ½ of a penny per unit had been reached. Although electricity cost twice as much as gas for roasting, which he considered the most suitable form of electric cooking, he could not see any advantage over food similarly cooked in a properly cleaned gas stove.

Professor BAILY thought that electric heating could not compare with the old coal fire. The results of a recent experiment in a house with three rooms and an occasional bedroom connected led him to assume that with electricity at 1d. per unit heating would cost £85 per annum. The electric radiator was suitable for putting under a desk or in a position where you could in a manner sit upon it, but otherwise as a heating adjunct he thought that it was of little use.

Mr. HENRY A. MAVOR pointed out a few contradictory remarks in the Paper. Electricity was bound to be more costly than coal for the general heating of a house, for the principal reason that the electric unit is produced from coal, steam, and a generating plant, from which a total of 10 per cent. thermal efficiency can only be obtained. He referred to the great convenience of electrically-driven vacuum cleaners, and advised the Corporation Electricity Department to advocate their extended use.

Mr. T. B. MURRAY confined his remarks to the consideration of the real cost of electrical power as compared with suction gas plant. At his firm's works, where they have a fairly constant load of about 40 h.p. driving machine tools, the annual cost of running a suction plant amounted to 0·455 pence per b.h.p. It would therefore appear that until electrical energy could be supplied at about ½d. per unit, it would not pay to adopt electric driving.

Mr. J. A. ROBERTSON, referring to experiments carried out by himself, mentioned that a 9 lb. roast could be cooked with 3 units, which at a 1d. per unit would be double the cost of cooking with gas at 2s. 8d. per 1,000 cubic feet. He did not think this expenditure extravagant when compared with the cost of the article to be cooked.

Mr. LACKIE, in reply, said he did not recommend the continuous use of electricity for heating at 1d. per unit. The question of electric heating should not be looked at solely from the point of view of cost, without considering atmospheric purification and absence of dirt and ashes.

LOCAL NOTES

Aberdeen: *Tramway Extension.*—The Tramway Manager has been instructed to prepare a report upon extending the tramway system to Footdee.

Bacup: *Tramway Construction Dispute.*—Some time ago the Corporation accepted a tender of Messrs. Macdonald & Deakin, of London, for tramway permanent way at £8,574. After paying, from time to time, sums amounting to £6,312, the Corporation declined to pay any further amounts, and when the contractors claimed to have the matter determined by arbitration, the Corporation set up the defence that, under the Public Health Act of 1875, municipal contracts over £50 must have the Corporation seal affixed to them. It has been held recently, however, that the affixing of a seal to a municipal contract is a mere formality once the work involved has been put in hand, or any goods supplied and accepted. In the Lancashire County Court at Liverpool, the Vice-Chancellor upheld this view, and gave the contractors the right to arbitration.

Birmingham: *Electrical Exhibit.*—The Electric Supply Department have exhibits at the Midland Institute Conversazione, held in the Town Hall and Midland Institute from January 10th to 14th, including a demonstration of electrical domestic appliances and electric welding.

Dawlish: *Electric Lighting.*—The Dawlish Electric Lighting Co. will shortly erect a generating station in Brook Street.

Dover: *Electricity Supply.*—The Electrical Engineer is to report upon giving a supply of electrical energy in St. Margaret's Bay.

Greenock: *Electricity Profits.*—The Secretary for Scotland has informed the Electricity Committee that all the profits from the Electricity Department should be placed to the reserve fund. Last year, of the net surplus of £3,000, the sum of £1,900 was applied to the relief of rates, and the remainder placed to reserve.

London: *St. Pancras: Criticism of Electricity Undertaking.*—It is stated that the Electric Lighting Committee is recommending the discontinuance of an advertisement in a local paper on account of the criticisms of the Electricity Department which have been made by the paper in question.

Manchester: *Tramwaymen's Hours.*—The Tramways Committee have sent a further communication to the Amalgamated Association of Tramway and Vehicle Workers with regard to the demand for an eight-hour day. It is pointed out that 63 municipal tramway undertakings work their men 60 hours per week, that only 15, including Manchester, work 54 hours per work, or nine hours per day, and that no tramway authority has adopted an eight-hour day. The Committee, however, are going into the question of making some further slight concessions in order to improve the men's pay.

In reply to this communication, the Secretary of the Men's Union asked for a definite answer as to whether the Committee will submit the whole case to arbitration.

Electricity and Gas Committees.—The Conference mentioned in our last issue to consider the policies and working methods of the Electricity and Gas Departments was held on Wednesday last week under the Chairmanship of the Lord Mayor. A statement was made by the Chairman of the Gas Committee, and the Conference was adjourned for the preparation of a statement on behalf of the Electricity Committee.

Rhyl: *Diesel Engine and Low Fuel Costs.*—The monthly report of Mr. E. H. Wright, the Borough Electrical Engineer, gives particulars of the reduction in generating costs since

Hosted by Google

the installation of the Diesel engine set. In December the generating costs were 0·79d. per unit, compared with 1·3d. per unit for December, 1909.

Stannos Wiring.—The Electric Lighting Committee, in order to encourage the use of the Stannos system of wiring, have opened a shop in the High Street, where an installation on this system may be inspected.

Scarborough: *Winter Tramway Service.*—At the Scarborough Police Court on Wednesday the Scarborough Electric Tramways Co. were fined 10s. for each day in respect of 28 days during which they had failed to carry out an order of the Board of Trade to maintain a winter tramway service. It was stated at the Police Court that the company's undertaking is in the hands of the mortgagees.

Sheffield: *Legality of Discounts.*—At the Council meeting last week, the action of the Electricity Committee in offering a 50 per cent. discount to those consumers doing away with all other means of lighting than electric light, was criticised, but the Town Clerk's opinion is that such discounts are perfectly legal.

Truro: *Electric Lighting.*—Mr. J. A. Purves, whose firm intended to apply for an Electric Lighting Provisional Order, has been compelled to abandon the application, it is stated, on account of the difficulties met with through the operation of Clause 2 of the Electric Lighting Act of 1909, which stipulates that a generating station cannot be erected on land which has not been specified as required for this purpose in an Act of Parliament.

Watford: *Tramways.*—The Council have appointed a small sub-Committee to meet the Highways Committee of the Hertfordshire County Council with a view to removing the points of difference between them concerning the proposed tramway system. The powers which the Council possess in Watford lapse in April, and there is a desire on both sides to preserve them.

Winchester: *Purchase of Electric Light Co.*—Messrs. Merz & McLellan have been appointed consulting engineers to the Corporation for five years in connection with the purchase of the Winchester Electric Light & Power Co. The Electric Lighting Committee intend to give immediate attention to the present system of charging, which they regard as unsatisfactory.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Bacup.—Tenders are invited by February 5th for high- and low-tension cables, ducts, transformers, and meters. Particulars from the Town Clerk.

Leith.—With a view to future extensions, the Town Council have purchased some additional land.

London: *Hammersmith.*—The Electricity Committee invite tenders for a 3,000-kw. turbo-alternator, E.H.T. feeders and L.T. distributors (see an advertisement on another page).

Oldham.—Mr. S. W. Newington, the Borough Electrical Engineer, who recently reported upon the need for considerable extensions at the Electricity Works, has been instructed to prepare a specification for a mixed-pressure turbo-alternator.

Turton.—Tenders are invited for the supply of overhead mains, poles, &c., for the electric lighting of the Bromley Cross area and Bradshaw Road. Particulars from Mr. R. B. Leach, Electrical Engineer, Council Offices, Bromley Cross, Bolton.

West Ham.—The Corporation require tenders by January 31st for engine-room stores, wattmeters, electrical fittings and accessories, single and two-phase motors, &c.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

PROVINCES.

Aberystwyth.—Additions to drill hall. Architect, G. T. Bassett.

Aldershot.—New secondary school.

Birmingham.—Telegraph stores, Bordesley. H.M. Office of Works.

Blackburn.—Additions to County Court. H.M. Office of Works, London.

Caterham.—Council offices and hall.

Enfield.—New infirmary. Consulting Engineers, Messrs. May & Hawes, London.

Farnham.—Extension to drill hall premises for Surrey Territorial Force Association. Secretary, Caxton House, Westminster.

Glasgow.—School buildings in Cathkin Road. Slaughter house, offices, &c., in Hill Street.

Gloucester.—Additions to School of Domestic Science. Architect, R. S. Phillips, Midland Bank Chambers.

Johnstone, N.B.—Proposed branch of the Clydesdale Bank.

Llanelly.—New church in Alban Road. Architect, E. M. Bruce Vaughan, Cardiff.

Maidenhead.—Administrative and laundry buildings at the Isolation Hospital.

Margate.—Concert hall, &c., at the Fort.

Oxford.—County offices in New Road.

Stoke-on-Trent.—Alterations at the Spittal Workhouse.

MISCELLANEOUS

Belgium.—Tenders are invited by January 26th by the Antwerp Municipal Authorities for the supply of carbons for arc lamps. Particulars at 73 Basinghall Street, London.

Bournemouth.—Tenders are invited by February 13th for the supply of stores for the Tramways Department, including electrical sundries. Particulars from the General Manager.

Hull.—The sum of £3,000 is to be expended upon converting the Sculcoats Bridge to electric working.

Leeds.—Tenders are invited for supplies of coal and for stores for the year ending March 31st, 1912. Tenders by February 21st. Tenders are also required for 1,500 alternating-current wattmeters by February 16th. Particulars from H. Dickinson, Borough Electrical Engineer. (See an advertisement on another page.)

Sheffield.—The Tramways Committee invite tenders for general stores, including car fittings, overhead line fittings, power station supplies, lamps, cables, &c. Particulars from the General Manager, and tenders by January 21st.

Turkey.—Tenders are invited by March 15th for the construction of tramways and the supply of electricity in Adrianople.

TENDERS RECEIVED AND ACCEPTED

Sunderland.—The tenders of Messrs. Rickard, Ltd., for V.I.R. service cable, and Messrs. Farrow & Co. for pavement boxes, wrought-iron tubing and bends, have been accepted.

Amongst recent orders received by the Mirrlees Watson Co., Ltd., for steam condensing plant are the following:—Surface condensing plants for Uxbridge & District Electric Supply Co., Ltd.; Anglo-Persian Oil Co., per Siemens Bros., two sets; M. Nairn & Co., Kirkcaldy, per C. A. Parsons & Co.; Usine de Tuiliere, Bordeaux, per Thomson-Houston Co., Paris. Barometric jet condensing plants for Chuwo Seito Kaisha, Formosa, per Okura & Co., London; C. & W. Walker, Ltd., Donnington; Durban Corporation, per Hubert Davies & Co., London (with three sets of hot-water and injection pumps and motors). Low level jet condensing plants for Edinburgh Corporation, per Brush Electrical Co., three sets; Dinnington Main Colliery, per British Thomson-Houston Co.

Messrs. David Bridge & Co., of Castleton, Manchester, inform us that they have placed another order for a Royce 10-ton electrical travelling crane for a further extension they have made. This now makes the third 10-ton electric travelling crane that has been installed to cope with the increasing business in friction clutches, hauling plants, and gearing installations generally.

Messrs. Willans & Robinson, Ltd., have recently received orders for four Willans Diesel oil engines, each to develop 282 b.h.p., for driving direct-coupled alternators. Two of these engines have been ordered by the Alianza Co., Ltd., London, and two by the Rosario Nitrate Co., London. In both cases, the consulting engineers are Messrs. Strain & Robertson, of Glasgow.

Electric Traction on the Brighton Railway.—It is announced that the London, Brighton & South Coast Railway have come to a decision to extend electric traction on their system as far as Croydon, provided the results of the extension now in hand are satisfactory. The Croydon Borough Council will supply part of the current required, and have sanctioned a further supply in their district being given by the London Electric Supply Corporation.

OSRAM·LAMPS

Hosted by Google

APPOINTMENTS AND PERSONAL NOTES

Efforts are being made to raise the sum of £2,000 for the benefit of Mr. F. S. Pepperdené, of Bexhill, who has had the misfortune to contract X-ray dermatitis in connection with his early work with X-rays. Subscriptions will be received by Dr. Murdoch, of Bexhill.

A recommendation of the Carlisle Electricity Committee to increase the salary of Mr. S. T. Allen, the Borough Electrical Engineer, by £50 per annum, with annual increments of £20 up to £450, has been postponed.

A draughtsman is wanted by a firm of telephone engineers and instrument makers (see an advertisement on another page).

The Limerick Corporation have appointed Mr. Cloran Borough Electrical Engineer at a salary of £200, rising to £300 per annum. The appointment was made at a somewhat stormy meeting, the general feeling being that an Irishman should be appointed. The Council's consulting engineer had recommended Mr. F. Swarbrick, of Leigh, Lancs.

The salary of Mr. R. Smith, Chief Assistant at the Worcester Electricity Works, has been increased from £140 to £156 per annum.

Mr. C. A. Frost, Assistant Electrical Engineer at Bexhill, has been given a gratuity of £25 for the efficient manner in which he carried out the duties of Chief Electrical Engineer during the absence of Mr. Le Feuvre, who met with an accident whilst in camp.

The following have been selected as the short list for the position of Tramways Manager at Oldham in succession to Mr. Lewis Slattery, who has been appointed to the L.C.C. Tramways Department:—C. Burgess, Wigan; J. W. Dugdale, Ashton; A. F. Eardley, Stockport; T. J. Kendrew, Southport; W. Murray, Walthamstow; A. Wolstencroft, Ilford.

An assistant installation inspector is required at the Stepney Electricity Works. (See advertisement in this issue.)

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £58 to £58 10s. per ton (last week, £58 10s. to £58 15s.).

Liquidations.—The Alsop Flour Process (1906), Ltd., is to be wound up voluntarily. Mr. F. A. Greenaway, 21 Mincing Lane, London, is liquidator.

Dissolution of Partnership.—H. Ward and E. J. Cox, Electrical Engineers, of Castleford and Dewsbury, have dissolved partnership. Debts by H. Ward.

Agency.—The Globe Electric Co., Ltd. (11 Farringdon Avenue, E.C.) have appointed Messrs. Walters & Co., Ocean Chambers, Waterloo Street, Birmingham, as their agent for Birmingham and the Midlands.

Bankruptcies.—The trustee in the bankruptcy of H. J. Burdett, Electrical Engineer and Contractor, 16 Regent Street, Rugby, has been released.

The G.B. System in the Mile End Road.—In the Appeal Court, before Lords Justices Vaughan-Williams, Farwell, and Kennedy, on Wednesday last week, an application was made, on behalf of Sir John Benn, to have the appeal against the judgment of Mr. Justice Ridley awarding £8,000 damages against him in respect of statements made concerning the G.B. system in the Mile End Road expedited. Mr. F. E. Smith, K.C., M.P., who opposed the application, stated that, so far, Messrs. Griffiths and Bedell had only been able to recover £100 of the £5,000 for which it was agreed security should be given. Most of Sir John Benn's furniture was claimed by other members of his family, and his shares in Benn Bros., Ltd., and the *Hardware Trade Journal* had been disposed of, with the exception of 50 shares in the latter. In the course of a discussion, it was stated that it was not usual to allow a bankruptcy petition to be made effective when an appeal was pending, but Mr. Smith said he did not know what the position would be in this case, as the stay of execution had been removed, through Sir John Benn not having given the security for the £5,000. Sir Edward Clark, who appeared for Sir John Benn, said that a judgment stood against him in respect of which he had apprehensions of very serious consequences to his public as well as private life. The Court refused the application on the ground that no good reasons for expediting the appeal had been put forward.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Chatham & District Light Railways Co.—The net revenue for the half-year to December 31st amounts to £10,198, of which £4,500 has been transferred to depreciation. After meeting a 5 per cent. dividend on the preference shares and 4 per cent. on the ordinary shares, a sum of £638 is carried forward.

Direct United States Cable Co.—A balance of £4,706 is carried forward for the December half-year, after paying interim dividends of 4s. per share for each of the two quarters and a bonus of 2s. per share for the December quarter, and placing £5,000 to reserve.

Musselburgh & District Electric Light & Traction Co.—It is stated that a new issue of capital will shortly be made.

Sao Paulo Tramway, Light & Power Co.—An issue of £300,000 five per cent. perpetual consolidated debenture stock is being made.

City & South London Railway.—A dividend at the rate of 1¾ per cent. has been declared, with £1,500 transferred to renewal fund and £1,788 carried forward.

Montreal Light, Heat & Power Co.—A dividend of 2 per cent. for the quarter ending the 31st inst. has been declared.

Telegraph Traffic and Movements of Cable Ships.—The El Arich route between Adana and Beyreuth was down on 13th inst.; while the Hanekin route was interrupted between Constantinople and Diarbekir and Constantinople and Aler.—The *Pouyer Quertier*, of the French cable company, has repaired the cable between Paramaribo and Cayenne, thus re-establishing connection with Dutch Guiana *via* Salinas. The route *via* Hayti is still down, as the cable between Puerto Plata-Martinique now requires attention.—The c.s. *Minia*, of the Anglo-American Telegraph Co., returned to Halifax, N.S., on the 28th Dec. Since her return she has been busy working on the main cable off Newfoundland, and has repaired three breaks.—The c.s. *Mackay-Bennett*, of the Commercial Cable Co., is still engaged on the Havre-Waterville section, which is being renewed.

Primary Cells for Telephone Purposes.—With further reference to the improved pattern of Leclanché cell devised by Mr. J. G. Lucas and Mr. A. Fraser, and described on page 3 of our issue of January 5th, we learn that the Post Office prepare these cells themselves, but that probably any suitable firm would supply them to order. If desired, the chemicals can be purchased separately from firms such as Townson & Mercer, Griffin, &c. We understand from Mr. Lucas that some 50 per cent. more manganese chloride than salammoniac is required. This means about 2·35 grammes of manganese chloride per ampere-hour. The cost per cell, we are informed, works out about the same for large quantities.

SUMMARY

We publish a description of the Brimsdown Lamp Works, in which several thousands of metal filament lamps are manufactured per week. The filament itself is made at the works. The various processes are briefly described, and illustrations are given of the filament "sintering," the welding, and the exhausting departments. (Page 41.)

An illustrated article describes some new electric cooking apparatus. (Page 43.)

The adjourned discussion of Major W. A. J. O'Meara's Institution Paper on long-distance submarine telephone cables was opened by the Postmaster-General. Mr. F. Gill, of the National Telephone Co., spoke of the use of loading coils on their underground circuits, and also dealt at some length with the question of "duplexing." Mr. D. Sinclair supported Sir John Gavey's advocacy of continuous loading, and Mr. A. Campbell and Mr. Mordey discussed the properties of iron at the low values of magnetisation obtained in continuous loading. Mr. F. Tremain pointed out the great saving in the land lines consequent upon a slight improvement in a short length of submarine cable in the circuit. Large conductors lightly loaded were advocated by Mr. W. P. Granville, while Mr. B. S. Cohen said that the reverse had given better results. (Page 44.)

A discussion on library lighting was commenced before the Illuminating Engineering Society on Monday, January 16th. All the speakers agreed that electricity is the only possible illuminant. In an endeavour to arrive at a standard of illumination in the various rooms of a public library, figures of the present illumination in many London libraries have been taken, these showing very inconsistent results. The standard of table lighting fixed for the Carnegie Library in Pittsburg is five foot-candles. (Page 45.)

Mr. H. Gray, in a Paper on electric cooking, read before the Manchester Local Section of the Institution of Electrical Engineers, gave results of tests to show that the cost of electric cooking with energy at $\frac{3}{4}$d. per unit could work out cheaper than gas at 2s. 6d. per 1,000 cu. ft. (Page 46.)

Messrs. Faye-Hansen and Harlow's Paper on the Merz-Price system of protection and certain modifications thereof, has been further discussed by the Birmingham Local Section of the Institution of Electrical Engineers. (Page 47.)

The anti-vibration metal-filament "Metalik" lamp recently introduced can now be obtained for the higher voltages. (Page 47.)

Among the specifications published by the Patent Office on Thursday last was one by S. G. Brown covering certain features of his telephone relay. A microphone transmitter for heavy currents and suitable for wireless telephony is described by A. Jahnke. Carborundum granules between iridium-platinum electrodes are cooled by the evaporation of alcohol in the granule chamber. The opposition to a patent by the Westinghouse Metallfaden-Glühlampenfabrik Ges. for a process of decarbonising tungsten filaments has been withdrawn. A patent by A. W. Leonard for an electric advertising device is opposed. The fundamental patent covering the construction of the well-known Berry transformer expires on Thursday next after the full life of fourteen years. (Page 48.)

In the patent action brought by the Osram Lamp Works, Ltd., against Messrs. G. M. Boddy & Co., judgment has been entered against the latter firm. Messrs. Philips, of Eindhoven, who manufacture the lamps sold by Messrs. Boddy, have taken a licence under the Osram patents. Under the terms of the licence, a royalty is to be paid, importation is to be kept within a certain scale, and there is an agreement to maintain prices and control discounts. We give summaries of the two patents under which the action was brought, and of two other patents which may influence the general situation. (Page 49.)

Hosted by Google

THE Coventry Tramway Company have been given notice to sell their undertaking to the Corporation.—The Scottish Office has modified its request with regard to the electricity profits at Greenock.—The members of the Islington Electric Lighting Committee, who recently resigned as a protest in connection with municipal wiring, have consented to continue in office.—The Metropolitan Electric Supply Co. have succeeded in getting their rateable value in Willesden reduced from £13,000 to £8,900.—The Manchester Tramways Committee and the Tramwaymen's Union are still in dispute as to the question of hours, &c.—An arbitration took place in London last week with regard to the purchase by the Hartlepool Corporation of certain tramway lines in their district. (Page 50.)

THE Wakefield Corporation require an 800-kw. alternator; a 600 or 750-kw. turbo-generator is required at Ipswich; and a Diesel engine set at Leek. An extension to the H.T. switchboard at Rawtenstall is required; H.T. and L.T. sub-station switchboards are wanted by the Calcutta Electric Supply Corporation; additional generating plant at Mansfield; additional boiler, economiser, &c., at Luton; and a new battery and generating machinery at Swindon. Edinburgh Corporation have been granted a loan of £75,000 for electrical extensions. Electrical stores are required by the Halifax Corporation and the Midland Railway Co. of Ireland. Leeds Electricity Committee require 1,500 A.C. wattmeters, and telephone material is required by the Australian Postmaster-General. (Page 51.)

THE conversion of the East London Railway Co. to electric traction is at present the subject of a survey by a leading electrical company. The considerable increase in the third-class traffic on the L.B. & S.C. Railway is attributed to the service of electric trains. The Aron Electricity Meter, Ltd., are inviting subscriptions for £100,000 five per cent. first mortgage convertible debentures at 97. (Page 53.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JANUARY 26TH.

Institution of Electrical Engineers.

8 p.m. At Victoria Embankment. (1) "Modern Long-distance Transmission of Electrical Energy," by W. T. Taylor. (2) "Extra High Pressure Transmission Lines," by R. Borlase Matthews and C. T. Wilkinson.

SATURDAY, JANUARY 28TH.

Association of Mining Electrical Engineers.

3.30 p.m. *Notts and Derbyshire Branch.* At University College, Nottingham. Discussion of Mr. E. K. Scott's Paper, "Electricity in New South Wales Coalfields."

5 p.m. *Yorkshire Branch.* At Royal Victoria Hotel, Sheffield. Discussion of Mr. E. K. Scott's Paper.

5.30 p.m. *Warwickshire and S. Staffs Branch.* At Imperial Hotel, Birmingham. Discussion of Mr. E. K. Scott's Paper. The question of Examinations will also be dealt with.

6.30 p.m *Lancs, &c., Branch.* At Grand Hotel, Manchester. Address by President, Mr. W. Maurice, and discussion on Mr. E. K. Scott's Paper.

MONDAY, JANUARY 30TH.

Junior Institution of Engineers.

7.30 p.m. At Caxton Hall, Westminster. Sixth and concluding lecture on "The Law Relating to Engineering," by Mr. L. W. J. Costello.

Illuminating Engineering Society.

8 p.m. At Royal Society of Arts. Adjourned discussion on Library Lighting.

TUESDAY, JANUARY 31ST.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. At University. (1) "Long-Distance Transmission of Electrical Energy," by W. T. Taylor; (2) "Extra High-Pressure Transmission Lines," by R. Borlase Matthews and Mr. C. T. Wilkinson.

WEDNESDAY, FEBRUARY 1ST.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. At Victoria Embankment. "Telephony," by H. Clark.

THURSDAY, FEBRUARY 2ND.

Institution of Electrical Engineers.

7 for 7.30 p.m. Annual Dinner at Hotel Cecil.

MANAGING DIRECTOR OF THE GENERAL ELECTRIC CO.:—Gentlemen, your services have been invaluable, you know, but this agreement gives me all I want at present. These cigars have the best flavour, but Dutch ones will not be contraband if they have paid us duty.

Hosted by Google

THE BRIMSDOWN LAMP WORKS

Manufacture of Metal Filament Lamps

THE making of metal filament lamps is one of the most interesting of electrical manufactures, and we therefore gladly accepted the invitation of the Imperial Lamp Works (Brimsdown), Ltd., to view their works last week. These works have only been in operation for a few months, yet the output is very great, as in addition to supplying a very wide general demand, they manufacture the large quantities of metal filament lamps which are sold by Simplex Conduits, Ltd. The machinery at present installed is working at its full output; 400 hands are regularly employed in manufacture, and when the works are completely equipped the estimated output of lamps will be 10,000 a day. The arrangement of the works has been carried out with a view to rapid and systematic manufacture, the organisation and supervision are excellent, and in the finely-built, lofty and well-ventilated shops the comfort of the operatives is secured, so that the product should certainly be of the highest possible quality.

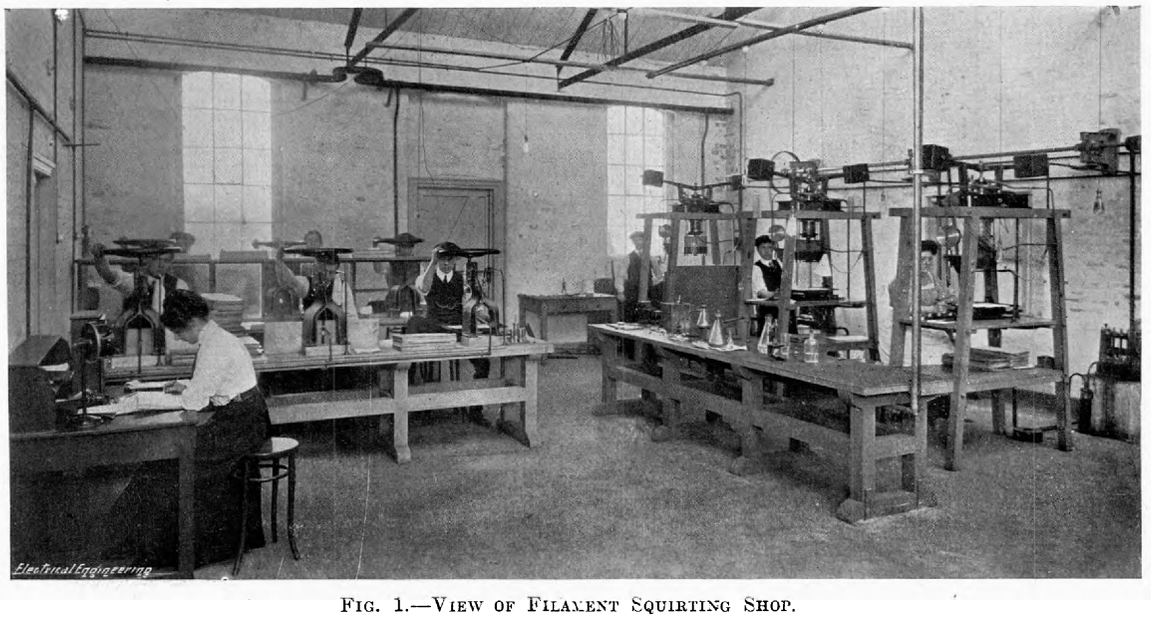

FIG. 1.—VIEW OF FILAMENT SQUIRTING SHOP.

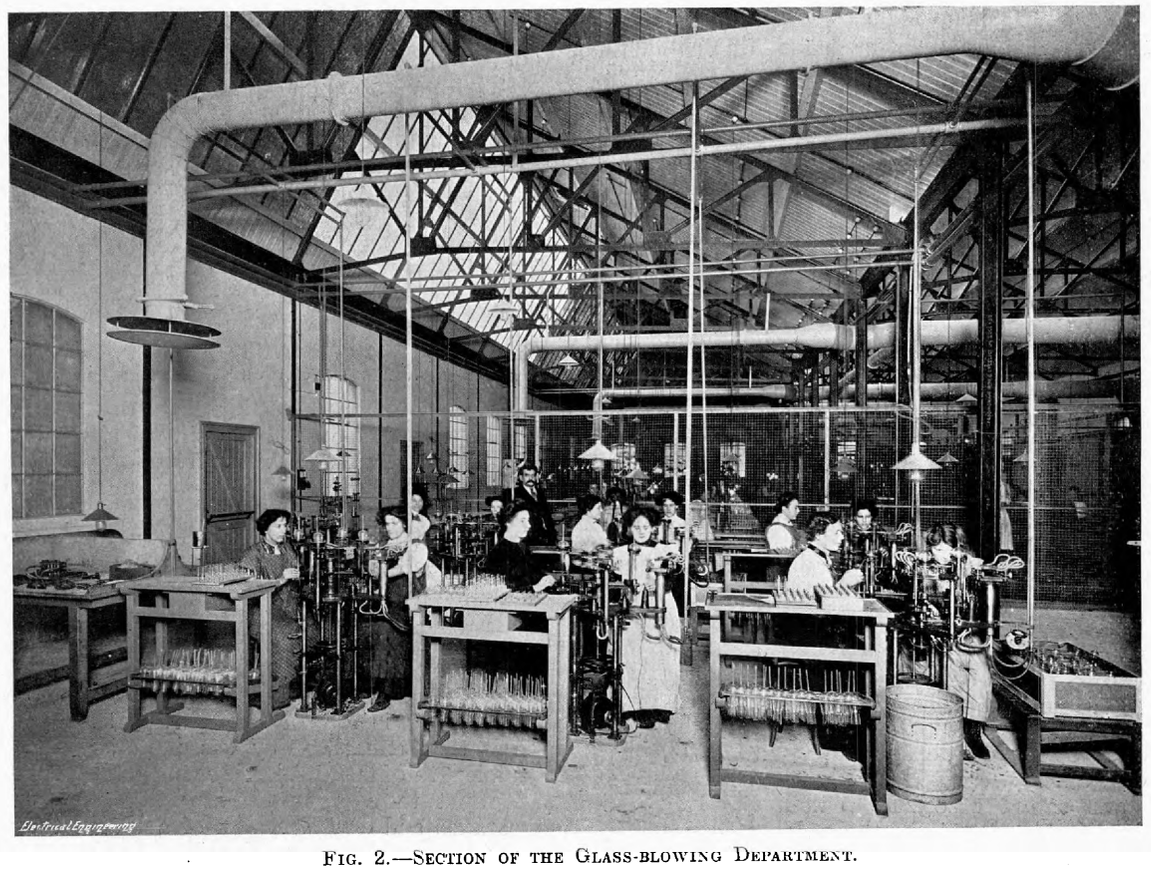

FIG. 2.—SECTION OF THE GLASS-BLOWING DEPARTMENT.

C

Hosted by Google

The Kuzel colloidal process is employed in the manufacture of the filaments. Pure metallic tungsten is produced in a colloidal form—the very highest state of sub-division—and is then worked between calenders into a sufficiently coherent mass for "squirting." This so-called squirting process consists in forcing the metal through diamond dies, out of which the filament comes continuously at a rapid rate, and is guided on to a tray of white paper. The filaments for the lamps of ordinary size are finer than a human hair, ranging from about one-fortieth of a millimetre upwards in diameter. Fig. 1 is a view of the squirting shop. In some of the machines the pressure is applied by hand, but in others (those seen worked by girls in the illustration) hydraulic pressure is employed. The filament is then cut to the approximate length required, and laid up U-shaped in bundles, and after being baked is passed on to the forming shop. Here each filament is placed in a pair of clips under a bell jar, and a tungsten wire is hung at the bottom of the U as a weight. The jar is then partially exhausted, and a certain amount of ammonia gas is let in, and current is passed through the filament, bringing it up gradually to a white heat. This is controlled absolutely automatically by a motor, so that the current is gradually increased up to a certain value, and then automatically switched off. The weight at the bottom of the loop gradually draws it down to the elongated V-shape used in metal filament lamps. As an indication of the magnitude of the operations, we may mention that there are 80 girls employed at the forming benches, each of whom can form a maximum of 600 filaments a day, and that the shop will shortly be doubled in capacity. Next, the filaments are cut to accurate length, weighed on torsion balances, and sorted according to their weight. The weight of each filament is in the order of one milligramme, and the lightness of touch and dexterity of the girls in handling the fine and barely visible threads of wire throughout these processes is remarkable.

Equal lightness of touch but greater skill is required in the mounting shop, and the rapid and accurate work shows that the girls have had exceedingly good instructors, besides having displayed considerable aptitude in becoming adepts in the few months that the works have been in operation. The skill and certainty in the successive operations of joining up the leading-in wires, and mounting and pasting the filaments is marvellous. In the mounting shop, the glass tube for the leading-in wires is first cut into short lengths, and then opened out. The leading-in wires are formed of short lengths of copper, platinum, and nickel wire welded together, the platinum being a short length to pass through the glass. We understand that a new material is being introduced in place of the platinum, which has, as platinum, the same coefficient of expansion as glass. The leading-in wires are inserted in their glass tube, which is pressed round them after being softened in a blow-pipe flame, the central glass stem is made with its circle of thin and flexible nickel hooks at the other end, and the filaments are placed in position and "pasted" to the lower nickel wires with a paste of finely divided tungsten paste. Then the pasted joint is electrically welded in an atmosphere of hydrogen, this operation being performed under a glass bell (Fig. 3). A thick screen of glass is fixed in front of the bell jar to protect the operator's eyes in the event of a slight explosion and shattering of the glass, which might occur if the welding be started before the bell is entirely full of hydrogen.

FIG. 3.—FUSING THE FILAMENTS TO THE LEADING-IN WIRES AND SUPPORTS.

The filament, securely mounted on its support, is then welded into a stemmed bulb in the ordinary manner, and the lamp passes to the exhausting benches. Rotary mercury pumps are employed; the glass stem at the end of the bulb ultimately to be drawn down to the "pip" is dipped in a chemical compound, the bulb is then exhausted by the pump, and sealed off with a length of tube projecting, and finally the filament is brought to a state of incandescence until the appearance and disappearance of a bluish tinge in the bulb gives the signal for the final sealing off. These concluding processes in the manufacture of the lamps have been purposely described more or less superficially.

The lamps are then tested, classified, and capped in the usual way.

In concluding this article, we must express our thanks

Hosted by Google

to Mr. E. Scharrer (General Manager and Secretary of the Company), Mr. G. Luedecke (the Works Manager), and Mr. J. J. Chiswell (the Sales Manager), for the indefatigable energy and patience with which they showed us over the works, explaining everything, replying to innumerable questions, and showing us a cordial and hospitable welcome.

SOME NEW ELECTRIC COOKING APPARATUS

SIMPLEX CONDUITS, LTD., are introducing a new system of electric cooking, to be known as the "Zoroaster" system. The only element used in the system consists of a high-resistance alloy mounted on mica in various ways, according to whether it is being applied to roasting, grilling, or boiling. In the water heating apparatus the application of the element differs considerably from what has been usual up to the present. The bottom of the water container carries a raised groove in which the element is inserted, so that practically an immersion heater is obtained which gives a very high efficiency.

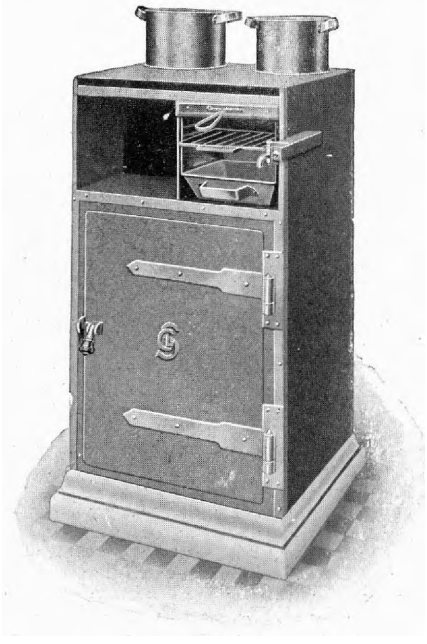

FIG. 1.—"ZOROASTER" LARGE OVEN.

Two types of ovens are now being introduced, the larger pattern being built of sheet steel plates with a cast-iron door resting on a suitable moulding. The internal dimensions of the oven are 18 in. by 14 in. by 14 in., and the whole of the oven is suitably lagged to the extent of 2 in., and is therefore thoroughly insulated against loss by radiation. The top of the oven is arranged for carrying out the subsidiary operations necessary in the preparation of a meal other than roasting; it is finished in bright polished steel, and divided into four sections. The two back sections are arranged as water boilers, a vessel containing the water, made of copper, being sunk into the top of the oven. The heating elements are arranged in the manner previously described. In addition to being able to boil water a steamer is supplied with the oven for using on top of the container, and although only one tier is included, two or three more may be added if necessary. These water boilers are of one gallon and three-quarter gallon capacity respectively, and suitable draw-off taps brought out to the front of the ovens are arranged for. The two front sections are also electrically heated, the right-hand side being arranged as a grill on top of which a kettle may be placed for water boiling. On the left-hand side there is a hot plate which may be used for frying and so forth. The chamber underneath the hot plate may be used for warming dishes. The total loading of this oven is 5 kw., degrees of heat (3 in the case of the oven) are arranged for in each case with the exception of the grill.

FIG. 2.—COOKING OUTFIT IN USE AT SIMPLEX SHOWROOMS.

The outfit can work for ten persons, and a recent test was carried out in the London showrooms of the company, putting into practice the oven for preparing a meal for seven persons, consisting of one quart of soup, six cutlets, 7 lbs. sirloin of beef, 2 lbs. of potatoes, 2 lbs. of sprouts, and twelve mince-pies. All this was prepared in slightly over two hours from the starting of the oven, at a consumption of 5·08 B.O.T. units, which works out at something under 1d. per person for the meal. Three or four additional persons could have been catered for without any great increase in the cost of current, as the oven was not fully occupied whilst the meat was being roasted. The actual outfit used is shown in Fig. 2. A smaller oven of similar nature is also made, and a combined cooker is being introduced, consisting of a grill and water-boiler similar to that used on the top of the oven, with a chamber for keeping food warm. This is shown in Fig. 3.

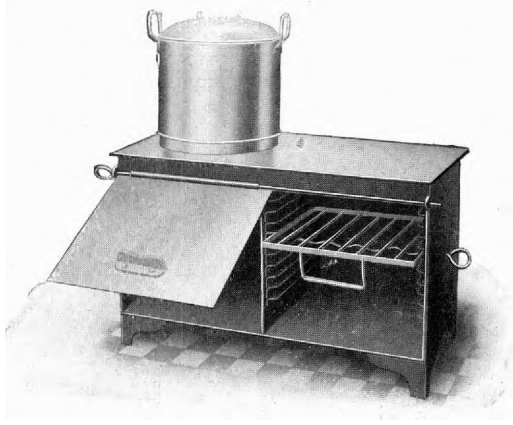

FIG. 3.—"ZOROASTER" COMBINED COOKER.

Osram-Robertson Dance.—A fancy-dress dance was held by the Osram and Robertson employees at the Brook Green Lamp Works on Saturday, January 14th. There were about 300 present, and prizes were presented by Mrs. C. Wilson to five ladies and three gentlemen for the most effective costumes.

The Buenos Aires Exhibition.—It is gratifying to learn from the revised list of awards at the recent Land Transport Exhibition in Buenos Aires that 83 Grand Prix were awarded to British exhibitors against 70 gained by Germany. The total number of awards is 926, of which 229 were taken by Great Britain, 170 by Germany, 155 by Italy, and 122 by France.

Leicester Chamber of Commerce Year-Book.—The first issue of a Year-book by the Leicester Chamber of Commerce is well calculated to stimulate interest in trade affairs in the important centre of the hosiery and elastic web trades. One of the objects of the publication is to demonstrate that Leicester possesses all the attributes of an economical manufacturing locality, and full particulars are given of the facilities for electric supply, communication, water supply, and so on. The book also contains an interesting historical sketch, and information as to sites for factories, &c.

Testing of Telephone Cables.—In a Paper read on January 16th at the Institution of Post Office Electrical Engineers, Mr. L. J. Sell described the tests applied during the drawing-in and jointing of paper-core telephone cables for electrostatic capacity, continuity, absence of crosses, resistance, freedom from contact, insulation resistance, absence of cross-talk, and pressure. The author advocated the use of the "looped end" (one end of the cable only being open) against the method of a "free end" (with both ends open), and discussed the advantages and defects of three methods of looping. In connection with the localisation of faults, the difficulty usually experienced with P.C. cable, of all wires being faulty, was noticed, and Messrs. Henley & Davage's patent for overcoming the difficulty by including an I.R.- or G.P.-covered wire in the cable was mentioned. The present method of desiccating with dry air was considered and criticised. Two alternative methods were suggested: one being to exhaust moist air by a pump and admit dry air; the other, the use of dry air with a varying pressure. In the discussion, the possibility of better results being obtained by other instruments (*e.g.*, the Secohmmeter and Bridge Megger) were suggested, and a graphic method of locating a pressure leak by taking observation of falling pressure at the two ends of the cable was described.

LONG-DISTANCE TELEPHONY

THE adjourned discussion of the Paper read before the Institution of Electrical Engineers on December 15th by Major W. A. J. O'Meara (Engineer-in-Chief to the General Post Office), on long-distance submarine telephone cables was concluded on January 12th. The Paper, in an abbreviated form, together with a report of the discussion, was given in ELECTRICAL ENGINEERING, December 22nd, p. 807. The Paper was concerned mainly with the new cable between England and France, and reasons were given why coil loading was adopted in preference to continuous loading.

MR. HERBERT SAMUEL (the Postmaster-General) said that in his room at the House of Commons he had been able to test the difference in speech between London and Paris on the old and new cables, and commented upon the extraordinary superiority of the new cable. The Chief Engineer to the Post Office had promised, if the Treasury would provide the necessary means, he would even establish telephonic communication between London and Calcutta at no great distant date. It was the desire of the Post Office to extend as rapidly as possible the radius of telephonic communication and to reduce the charges. Thanks to the new cable, they would be able in the near future to reduce by 50 per cent. the charges for communication between London and Paris. The Post Office was no longer a mere institution which sold stamps and carried letters, but was already the largest electrical business in the country.

Mr. F. GILL (Engineer-in-Chief to the National Telephone Co., Ltd.) could not reconcile the attenuation constant given by the author for the new cable with the stated gain of 17 miles of standard cable. He believed the attenuation constant was correct, but that the gain should be 14·28 miles. He thought the author had shown that continuously loaded submarine cables had no claim except when the mechanical difficulty prevented the use of loading coils, and it would seem that Messrs. Siemens had got over this difficulty. In the case of land lines the unsuitability of continuous loading was even more evident on account of the extra diameter of the cable requiring increased lead sheathing and duct space. With regard to the continuously loaded cable designed by Sir John Gavey, assuming that this had a length of three miles, it could be replaced by a 70 lb. cable with two small loading coils, which would give equivalent speech. The National Telephone Co., he continued, had numerous short lengths, aggregating 2,500 miles of loaded cable, working. As an example, in a 3½-mile length of 20 lb. cable they had two coils, and the equated length was reduced from 3·5 to 1·9. At present they had no cable with only a single coil, but experiments indicated that with one coil only in a short length, an improvement of 1·2 to 2 could be obtained. He thought that if Dr. Thompson carefully considered his proposal for parallel loading, he would see that it was entirely unsuitable for telephone conditions. He did not think there was any need, as yet, for a change in nomenclature. It was useless to give the attenuation constant without stating at what frequency it was measured. He then described the method of "duplexing" two telephone circuits by forming a third "phantom" circuit by means of repeating coils. Although there would be a loss on the two "physical" circuits, after a certain length there would be a gain on the phantom circuit, which, in fact, would be better than the two physical circuits before the coils were introduced. Making certain assumptions with regard to the land lines, he estimated that the old circuit from London to Paris had an equated length of 23·4, and the new, an equated length of 15·18. If the old cable were duplexed, a gain of about 10 miles might be expected on the phantom circuit, so that it would give a better result than that obtained by the new cable. Still, there would be a loss on the two physical circuits; and the question arose as to whether it was not possible to limit these to short distances, and to let the phantom circuit take care of the long distances. He would like to know whether it was proposed to load the aerial circuit on the new cable, and also whether both sections of the line were to be duplexed. Mr. Carty had shown it was possible to make a further improvement by loading the phantom circuit, but, of course, this was not possible at the time the new Anglo-French cable was laid.

Mr. DANE SINCLAIR (British Insulated & Helsby Cables, Ltd.) said that although scientifically and practically the Pupin coil method was the best, yet it was the duty of every engineer to see if he could get something nearly as good or better in some other way. If Pupin coils were introduced every three miles between London and Glasgow, it would be like reintroducing the old test-boxes, which were the cause of so much trouble to telegraph engineers. Sir John Gavey had approached his company some time ago with a view to producing the same results without such an enormous number of boxes. They found they could get an improvement of something like 60 per cent. by putting iron round the copper, and 102 per cent. improvement was obtained on short lengths. He did not agree with Mr. Gill that the cost of the pipe was so important, as in most cases sufficient duct space was already available. His experiments went to show that at least 100 per cent. improvement in the speaking could be had at an extra cost of 50 per cent. by using a quantity of iron which was just equal to half the weight of copper.

Mr. F. TREMAIN (Engineer-in-Chief's Department, General Post Office) gave some further particulars of a composite core telephone cable designed by him in 1901 for the Anglo-Dutch service, and referred to in the appendix to the Paper. With regard to the possibility of establishing communication between London and Astrakan with 800 lb. conductors, he pointed out that this would involve the use of 1,600 tons of copper, which, including the cost of the wayleaves, would give a total cost of the aerial line for each submarine cable pair of £152,000. It would seem worth while, therefore, to pay a considerable sum for a slight improvement in the submarine cable connecting up the aerial line, as it might render possible a reduction of gauge for the aerial wire. Loaded aerial lines, he said, would be much more susceptible to interference from outside sources than unloaded wires. With regard to the objections against aerial lines, he believed that a pair of the London-Glasgow telephone wires, which weighed 300 tons, and should equal 9 miles of standard cable, were in practice only equal to 14 miles on account of the underground portions at each end. In connection with Dr. Thompson's suggestion, he had tried inductive shunts early in 1901, but had found that the improvement was very slight as compared with that obtained with much smaller inductances in series.

Mr. B. DAVIES (Eastern & Associated Telegraph Companies) described a number of experiments carried out on an artificial line in the laboratories of the Associated Telegraph Companies, with the object of producing a distortionless cable. An absolutely distortionless cable was produced, but although the signals came out crisp and sharp, they were very attenuated, and the idea of distributed loading was abandoned because the plain cable gave considerably higher speeds in the majority of cases.

Mr. W. W. COOK (National Telephone Co., Ltd.), referring to the possibility of speaking between London and Astrakan or Calcutta, thought the author had not attached sufficient importance to the point raised by Sir John Gavey regarding the reduction in the effective conductivity of these long lines. He hoped that the improvements in loading submarine cables would result in greater attention being paid to communication between England and Ireland. At present, to get from the south of England to the south of Ireland the route was by way of Scotland. Referring to the line between London and St. Margaret's Bay, he mentioned that 79½ miles of this was 800 lb. conductors, the remaining being of lighter gauge. A slight improvement in the short lengths of lighter wire would have enabled a 400 lb. wire to be used for the main length, thus saving 28½ tons of copper. From the tests in the paper he calculated that the experts had only just been able to speak over a distance of 95 standard miles, and if that were so, speaking between London and Astrakan could hardly yet be considered.

Mr. ALBERT CAMPBELL (National Physical Laboratory) gave the results of some tests carried out at the National Physical Laboratory for Sir John Gavey and Mr. R. K. Gray on lengths of cable continuously loaded with iron strip. Tests at different frequencies showed that the leakance was practically proportional to the frequency; inductance was constant, and the effective resistance was almost constant except at the highest frequencies. He thought there was more future for continuously loaded cables than there appeared to be at present. The important factor was the value of permeability for low values of $\mathbf{H}$. He gave some results of tests on the permeability of iron strip before and after winding on the copper core, which showed that to get the best results it was necessary to anneal the strip in hydrogen after it had been wound on the core, as winding the strip neutralised the good effects of annealing. This annealing more than doubled the initial permeability for very low values of $\mathbf{H}$. With such cables he thought it would be possible to calculate the constants accurately from the known value of the permeability. He had previously recommended the use of silicon and aluminium alloys of iron annealed in this manner for this purpose.

Mr. W. M. MORDEY showed a permeability curve for stallov iron at very low values of $\mathbf{H}$. Up to a value of $\mathbf{B}$ equal to 2, the induction was proportional to $\mathbf{H}$. A curve of retentiveness showed that this was zero at about $\mathbf{H}=0{\cdot}1$. There would, therefore, be no hysteresis at this point, and it would seem to be the most favourable condition for continuous loading. These irons also gave a very high specific resistance, which was also advantageous. Winding the strip on the core would not reduce the permeability much, but might increase the hysteresis considerably.

Mr. W. P. GRANVILLE thought the statement that a three-fold

Hosted by Google

improvement had been obtained by the use of loading coils, whilst perfectly correct, was somewhat fallacious. It really came to a consideration of what could be done with a given amount of money. By using 400 lbs. of copper and 270 lbs. of gutta-percha instead of 160 and 300 respectively, he said that a gain of double could be obtained without the use of loading coils. Such a cable would give the maximum effect with only 20 milli-henrys of inductance against the 50 rendered necessary by the use of a small conductor, which was used in the new Channel cable, whilst there was a 25 per cent. gain in the attenuation constant. Further, this cable would enable the use of fewer inductance coils, enabling them to be spaced further apart, thus reducing the mechanical difficulties. He thought they would have to look to larger conductors lightly loaded in order to get the best results, with perhaps some form of air space, and this really brought them back to the continuous form of loading introduced by Krarup on the Continent.

Mr. B. S. COHEN (National Telephone Co., Ltd.) said the National Telephone Co.'s experience went to show that light conductors heavily loaded were better than heavy and unloaded cables. Probably better results would have been obtained from the Channel cables if the end loading coils on either side had been placed in the cable house instead of half a knot out; the improvement might have been 10 per cent., as it would have given a certain amount of loading on the open wire line serving the submarine cable. He showed some curves to demonstrate the effect of leakance on a 200-mile length of 200 lbs. open copper line loaded to 0·052 henrys per mile. When the insulation resistance was about 0·2 megohms per mile loop, the loaded line was no better than the unloaded as regards speaking. When the insulation resistance was 2 megohms per mile loop, the loaded cable showed to its full advantage above the unloaded and remained at this value almost independently of the insulation resistance. Thus, with ordinary maintenance, leakance should not play a serious part in reducing the efficiency. He agreed with Mr. Gill as to the inadvisability of departing from the present "standard-mile," and also mentioned instances in which different expressions were used by different people for the same thing in connection with attenuation constant and wave-length constant. He thought they would be able to do away with speech testing in the future and substitute some method which would eliminate the personal equation, but he could not follow Mr. Whalley's argument when he stated that the speech tests made on the Anglo-French cable were not satisfactory. The people making the tests had not become expert, and this accounted for the discrepancy in the results. With regard to Dr. Thompson's method of parallel loading, curves were shown giving the variation with frequency in the attenuation constant on a 20½ miles lines. For ordinary cable, the attenuation constant varied between 0·09 for a frequency of 600 and 0·12 for a frequency of 1,100, while with parallel loading a very much greater variation was obtained.

Mr. J. G. HILL gave comparative figures in support of his contention that speech tests were in close agreement with the results of electrical tests.

Mr. J. E. KINGSBURY disagreed with the possibility of eliminating the human element, as any instrument used would have to be calibrated by the human voice. He rather thought that Major O'Meara intended his statement as to talking between London and Calcutta to be illustrative.

Major O'MEARA briefly replied to one or two points, and will communicate his full reply in the Journal. He had been reported as having said in Paris that it would be difficult or impossible to maintain a loaded cable, but this was not correct. The point was that cables broke down in the majority of cases because ships in distress dropped their anchors and got hold of the cable, and the easiest way to release themselves was to cut the cable. Only three faults on the cable between London and France were due to different causes, and none to faults in manufacture. Successive repairs might easily result in a 100 yards or so of additional cable being added, and then, of course, an unequal spacing of loading coils arose, and that was the point which he had wished to make in Paris. If Dr. Thompson would give some further information as to the inductance that should be inserted and the spacing for some particular cable, he would be only too pleased to give his system of loading a trial on a subterranean circuit, but there were reasons why parallel loading was not one that could be considered in the case of submarine cables. With parallel inductances considerable difficulty would be experienced in localising faults. Professor Fleming had asked whether the dielectric current was a true conduction current; he rather thought it was a polarisation current. These cables were tested with continuous current at 100 volts, and so far there was no appearance whatever of anything in the nature of conductance leakage. In reply to Mr. Whalley, he said that the voice tests did not agree exactly because they were made under very different conditions. Of course, there might be certain reflection losses owing to the arrangement of the circuit. In the speech tests the average frequency was taken, and the differences to which Mr. Whalley drew attention were due to the fact that on the Continent they used a different testing frequency. He hoped that eventually one frequency would be used in all countries.

LIBRARY LIGHTING

ON January 16th the Illuminating Engineering Society commenced a discussion in conjunction with the Library Association, on the lighting of libraries. The subject was introduced, in a non-technical manner, by Mr. J. Duff Brown, the Islington Borough Librarian, and Mr. L. Stanley Jast, Croydon Borough Librarian, who indicated the chief requirements of efficient library lighting. Neither of these gentlemen spared their criticism of the attitude of architects hitherto in sacrificing efficiency of illumination to their love of symmetry of the fitting, with the general architectural features of the buildings with which they deal. Mr. John Darch, an architect, suggested that there should be legislation to enforce sensible illumination of public libraries in the same way that there had been legislation in connection with factory lighting. The one general principle agreed upon at the meeting was that there should be some form of general lighting of the rooms, with local lighting of tables, book shelves, &c. The object of the discussion was, if possible, to arrive at some standard of illumination in this connection. Mr. L. Gaster and Mr. J. S. Dow had been conducting an investigation into the illumination of various public libraries, in order to assist in achieving this object.

Mr. L. GASTER said that in connection with the lighting of the Carnegie Library, Pittsburgh, it was decided that all naked lights should be avoided. Holophane globes were used for the general lighting, and there were also table standards from which the reader's eye was completely protected, the shades being so arranged that considerable light was distributed sideways. The standard of illumination for the tables was fixed at 5 ft. candles. Reference was next made to the Patent Office library. Standards had recently been put upon the tables, and whereas originally the illumination was only 1·6 ft. candles, it was now from 10 to 12 ft. candles. At the same time he thought the standards were too far apart, as it left a considerable portion of the tables in comparative darkness. The library in the new building of the Institution of Electrical Engineers was very inefficiently lighted, but he would not criticise this installation because it was still being experimented with. Undoubtedly, table lamps would have to be installed.

Mr. J. S. Dow said that after a tour of many public libraries in London, his impression was that he rarely met a case in which the intensity of the illumination on the book was too low. One fault was the too frequent use of naked lamps, and the glare resulting from them could easily be avoided by a small change in the shade. Prof. Weber had laid it down that when the relative brightness on the book to that of the surroundings was more than 100 to 1, then there was an effect which was trying to the eye. He had not come across a case in which this existed. At the North Islington library the illumination on the tables was only 2 ft. candles. There was a very inefficient shade used at Islington, and in this connection he expressed the belief that it would be easy to devise a shade which had a polar curve, so that more light would be thrown sideways than downwards. At the Fulham reading room the newspaper standards were badly lighted, the illumination at one portion of the sheet being 4 ft. candles, and at another 0·4 ft. candle. Indeed, the ceilings had a greater illumination than parts of the newspapers. In the students' reference room in this library the illumination was 3 to 4 ft. candles, and the surface brightness of the surroundings 0·3 ft. candle, giving a very pleasant effect. The defect at the Islington Central library was that the lamps projected below the shades, and affected the eye of the reader. The lighting of the Surveyors' Institution, London, was one of the worst examples which he investigated. The illumination on the tables was only 0·5 ft. candle, and on the bookshelves it varied from 0·4 to 0·16 ft. candle. At the Royal Colonial Institute there was only general lighting by means of holophane globes, but owing to the surface brightness, the lighting was quite good. He believed the Patent Office officials preferred the table standards a good distance apart in order to provide room for books which were only being referred to occasionally by the reader. One of the best examples of library lighting was to be seen at the British Museum. There was an immense dome with five arc lamps hung very high up in specially frosted globes, and, in addition, 300 shaded table lamps, and nowhere was the illumination less than 3 to 4 ft. candles on the tables. It should be pointed out that all the speakers in the discussion were of the opinion that electricity is the only possible illuminant for libraries.

The discussion was adjourned until Monday next, January 30th.

Electric Power in German Mines.—According to *The Mining Journal*, over one thousand million units were utilised in German mines during 1909, 700,000,000 units being used in the coal mines of Westphalia and Upper Silesia. It is also stated that in some collieries where the electricity is generated from waste heat, and where from 5 to 10 million units is consumed per annum, the cost per unit, including interest and depreciation, amounts to from 3/16d. to ⅜d.

ELECTRIC COOKING

A PAPER entitled "Electric Heating as Applied to Cooking Apparatus," by Mr. H. Gray was read at the meeting of the Manchester Local Section of the Institution of Electrical Engineers on January 17th. The author emphasised the importance of robustness and reliability in electric cooking appliances, and strongly advised all such apparatus to be earthed. Passing on to questions of efficiency and cost, he said that gas (at 2s. 6d. per 1,000 cu. ft.) gave 20,000 B.Th.U. for 1d., while electricity (at ¾d. per unit) gave 3,400 B.Th.U. On this basis he worked out results of tests of water evaporation by gas and electrical heating, showing, in the case of gas, an average cost of 0·156d. per lb. of water evaporated, including heat required to raise the water and cooking vessel from cold. The efficiency varied a good deal with various types of electrical apparatus, being, for example, 91 per cent. for a self-contained saucepan and 62·4 per cent. for a flat-bottomed earthenware pot on a hot plate. The best figure arrived at was 0·275d. per lb. of water evaporated, including heating up. Tests with ovens in which a known quantity of bread was baked in a measured time gave 0·116d. per lb. of bread for gas, and 0·076d. for electricity at the same prices as above. The fact that the electrically-cooked bread took a shorter time to cook than that done in the gas stove is attributed to the more uniform heat in the electric oven, and the door not having to be opened so often. From the tests generally, it is seen that with the small cooking vessels gas is cheaper than electricity at the prices named, but with ovens there is a great advantage lying with electricity. The total amount of energy taken by the small pots and pans in working practice is only a small proportion of the energy taken in oven work, so that in general practice there is little reason to doubt that for overall economy electricity can and does compete with gas in price if suitable apparatus is forthcoming.

Comparing various classes of apparatus, he said that the hot-plate system had the advantage that the plates, not having to be moved, could be efficiently earthed. The cost of the hot-plate system was less than the self-contained one, and the simplicity of operation was much improved. The principal objection is the lower efficiency; whether this low efficiency was a serious disadvantage or not depended on the price per unit paid. A price above ½d. per unit was likely to render this system prohibitive, except where price considerations are of no moment. In the self-contained system, no attempt was usually made at earthing, and the use of flexibles and plugs was also a disadvantage.

The design of ovens was then considered. A working temperature of about 350° F. should be attainable in about 15 minutes. There should be uniform heat throughout the cooking area, and a steady movement of the hot-air currents in the correct directions, to avoid "airlocks" round the food. The arrangement adopted by the writer (described in ELECTRICAL ENGINEERING, Sept. 8th, 1910, p. 573) was to generate the heat at the bottom, deliver it then into vertical "flues," the flues passing it into the oven proper at the top. The hot air is then forced from the tops by fresh hot air continually rising in the flues—through all the area containing food—to the bottom, where it again comes in contact with the heating elements, and the process then repeats itself. With regard to retaining the heat in the general body of the oven, the general practice is now to have the oven double-jacketed with the hollow walls filled with dry air retained in a cellular state by means of finely divided asbestos or slag wool. Both of these materials give excellent results if the jacket is made 1½ in. to 2 in. thick. The switchgear and connections require to be carefully thought out, and to be as simple as possible. The author prefers the use of a small controller operated by one handle for controlling the degree of heat to several tumbler switches.

The author described a convenient switchboard, mounted on a cooking table, in which the flexible leads are attached to the board, plugged on to the apparatus when required, and drawn out of the way when not in use by counterweights, after the manner of the cords on a telephone switchboard. It was sometimes inconvenient that a more continuous degree of heat regulation could not be obtained, and the use of a water-heater with three heats in series with an ordinary cooking utensil to give an extra number of steps was suggested.

The high cost of electric cooking apparatus was sometimes a source of complaint, but was principally due to the output as yet being limited, and the designs not firmly established, hence manufacture on factory lines with large outputs is not being undertaken. The price per unit at which power can be obtained for domestic uses, continued the author, will ultimately be the most important factor. Two public authorities already supply at ½d. per unit. A considerable number charge 1d., and the range of prices in the future is likely to generally be between these two figures. A charge of over a 1d. per unit will generally confine the use of electrical cooking gear to well-to-do people with whom the somewhat increased cost over gas or coal is negligible compared with the advantages obtainable. At ¾d. per unit, and with apparatus turned out in quantity, nothing should in the future stop great developments. It must not be forgotten that the amount of power and heat which houses can absorb must be throughout the country more than that taken in industrial works, and an enormous field is thrown open for development.

DISCUSSION.

Mr. S. J. WATSON (Borough Electrical Engineer, Bury) inclined rather to the hot-plate system, in spite of its lower efficiency, and was interested in Mr. Gray's system of regulation by a series water heater. He thought that the variation of the charges in different places from ½d. to 3d. per unit was absurd, and believed that the rateable value system of charging would be largely used in the future.

Mr. A. J. CRIDGE (Sheffield Corporation Electricity Department) thought that the term efficiency was rather misused in connection with heating apparatus, as the whole of the energy used was turned into heat. He considered that 3 kw. was excessive for an oven, and regarded the use of a thermometer as unnecessary. Cooking was not purely a question of temperature. The "Telephone" system of charging had the disadvantage that, being based on the size of the installation, it prevented people from installing apparatus as freely as they otherwise might. Light, shiny ovens, such as the "Tricity" oven, wasted much less heat than black, heavily-lagged apparatus, as the latter radiated much more. Threepence should cook a lunch for twelve persons.

Mr. F. S. GROGAN (Berry Construction Co.) showed some examples of "Tricity" apparatus, and said that the extended adoption of electric cooking was largely a matter of educating the public. He advocated hiring out of appliances by the supply authorities at a moderate rental. He had shown by tests that gas at 2s. 6d. per 1,000 cu. ft., and electricity at 1d. per unit gave a small balance in favour of electricity, and thought that Mr. Gray's figures for gas were too low. He was strongly in favour of the hot-plate system. He agreed with the last speaker that lagged ovens were very expensive to work, and regarded the complete outfit described by the author as being out of all proportion in first cost to what the public were prepared to pay. As regards boiling water in bulk, electricity could not compete with coke or gas.

Mr. J. FIRTH had made tests which agreed pretty well with the results in the paper. The thing that was keeping electric cooking back was the first cost of the apparatus. He suggested that rheostatic control would sometimes be found useful.

Mr. EUSTACE THOMAS called attention to the case of a country house with an independent suction gas installation. With a slightly larger plant than required for lighting only, the cost of the extra units required for working would be less than that of working by gas or coal.

Mr. J. S. PECK (British Westinghouse Co.), said that cooking apparatus was not so satisfactory for voltages of 200 or over, as for lower pressures.

Mr. T. H. HURST also spoke, and the author replied briefly.

Annual Dinner of the Birmingham Local Section of the Institution of Electrical Engineers.—The fourth annual dinner of the Birmingham Local Section of the Institution of Electrical Engineers was held on the 18th inst., at the Grand Hotel, Mr. M. R. Railing, Chairman of the Section, presiding over the assemblage, which numbered upwards of 100 members and their guests. Mr. Railing, in proposing the toast of the Institution, said that the Midlands were nearly the centre of the electrical industry of the country, and that the many large works in the district compared very favourably with those in any other country. Major W. A. J. O'Meara, C.M.G., responded, in the unavoidable absence of Mr. Ferranti. He regretted that the public did not appreciate the advantages which they derived from engineers. He considered that engineers were themselves to blame, as they did not take a sufficiently active part in public affairs. Mr. H. Hirst gave the toast of the Birmingham Local Section, and referred to the great advantage to trade, due to the existence in their midst of the Birmingham University and the Technical School. Mr. A. M. Taylor, Vice-chairman of the Section, in responding, said that the Section, which started ten years ago, now numbered 400 members. He prophesied plenty of work for all branches of the profession when the greater Birmingham scheme was approved. Mr. R. K. Morcom proposed the electrical industries and the guests, and Mr. C. H. Wordingham and Mr. T. Harding Churton replied.

THE MERZ-PRICE SYSTEM

THE Paper by Messrs. K. Faye-Hansen and G. Harlow describing the Merz-Price system of protection and certain modifications thereof, recently read in Manchester, was further discussed last Wednesday by the Birmingham Local Section of the Institution of Electrical Engineers.

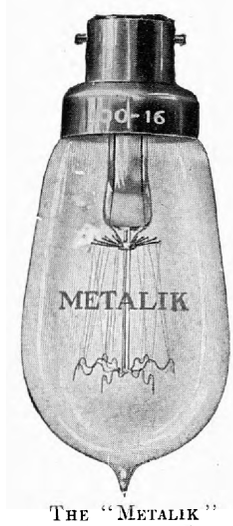
Mr. A. M. TAYLOR (Birmingham Electric Supply Department) pointed out that the systems described by the authors involved the scrapping of all the overload trips with fixed and inverse time limits which had only just been installed. He thought that the auxiliary resistance employed by the authors was good for current balancing. With regard to cutting out a faulty section, it did not appear that this was effected until the current had reached a very high value. Relays would operate in $\frac{1}{60}$ second, but oil switches required a much longer time, perhaps $\frac{1}{5}$ to $\frac{1}{2}$ second—a period sufficiently long to allow of serious damage being done. He had devised a switch which would operate in $\frac{1}{300}$ second, and which therefore broke the circuit before the current wave had reached more than, say, a quarter of its maximum value. He had also devised a relay, the action of which became more powerful as the voltage dropped, and he hoped to be able to arrange a system of discriminating relays which would obviate the necessity for the use of pilot-wires. These increased largely the cost of the cable system, and involved greater risk of breakdown. He inquired what was the effect of heavy faults on a system protected by Merz-Price gear with regard to the coming out of step of synchronous machines.

Mr. A. D. CHAMEN (South Wales Electric Power Distribution Co.) considered the Merz-Price system necessary on a large A.-C. distribution. The proposal to dispense with relays and batteries and use A.-C. trips was not a good one from the point of view of maintenance. It was a very simple matter to overhaul and test periodically a relay and battery, but it was a more difficult matter to do this in the case of an A.-C. trip. Although only two pilot wires were necessary, extra transformers and resistances were required, and he did not think there would be any great reduction in the cost. Capacity troubles had already been quite overcome. As regards sensitiveness, the short-circuit current at a fault initially reached a higher figure than that given by the authors, but in case of a fault the section was cut out before it had time to affect the running of synchronous plant. The Merz-Price gear did not entirely remove the need for overload relays, which were still required at places. He used fixed time-limit relays on feeders and instantaneous relays on interconnecting cables. In the case of a bank of generators the Merz-Price gear was very useful, even if it did not cut out a machine when a fault occurred between turns on one phase. As a rule, such a fault soon developed into one between phases when the gear came into operation. With an overhead system of supply mains, the breakage of a wire caused a high-resistance fault owing to the bad earth, and consequently the current was not large enough to operate the trips. To remedy this he had to run a catenary wire, which joined up all the earth wires on each pole.

Dr. KLOSS (Siemens Bros. Dynamo Works, Ltd.) thought that the great merit of the Merz-Price system was that it cut out a fault during development, whereas an overload relay required the current to reach a high value. He asked whether the harmonics which occur on E.H.T. systems would not have an effect in upsetting the balance. The switch suggested by Mr. Taylor would, by its rapid action, induce an extra high voltage due to the high rate of change in the value of the current.

Dr. GARRARD (General Electric Co.) put in a plea for simplicity. The Merz-Price system involved a quantity of auxiliary apparatus and pilot cables, which meant greater liability to breakdown and necessitated new trenching. Duplicate feeders, he thought, should not be connected to the 'bus-bars, as in that case they did not form a proper reserve. The balanced current system was the most easy to test. He saw no need to join up two generating stations to the same main; it was better to arrange for separate running with interconnecting links in case of necessity. The Merz-Price system of protection was not, in his opinion, of much use for generators.

Mr. G. HARLOW, replying to the discussion, said that fixed and inverse time-limit devices still had their place. No trouble was experienced with synchronous plant. The high value for short-circuit currents was only reached at points close to the station, and the saturation of the transformer magnetic circuits prevented this increasing beyond a certain value. The Westinghouse oil switch operated in one-tenth of a second. With reference to Mr. Chamen's criticism of the modification due to the authors, the A.-C. trip was quite easy to test. With the pilot wire broken, the trip operated with 30 per cent. of full load. He claimed that the cost of the authors' system was less than that of the relay and battery arrangement. It was a difficult matter to balance transformers exactly. Fixed time-limit overload protection was necessary at the generating end of a feeder. He agreed with Dr. Kloss that there was a possibility of trouble due to harmonics.



CATALOGUES AND PAMPHLETS, &c., RECEIVED

MINING SWITCHGEAR.—A pamphlet from Messrs. A. Reyrolle & Co., Ltd. (Hebburn-on-Tyne), contains a reprint from a contemporary of a paper by Mr. H. W. Clothier on "Mining Switchgear," which was read before the National Association of Colliery Managers at Edinburgh in November last.

AUTOMATIC SWITCHGEAR.—A new edition of the catalogue of "Empire" electric control gear has been issued by Electric Control, Ltd. (177 Reid Street, Bridgeton, Glasgow). An important production of this firm is the line of noiseless automatic A.-C. solenoid switches and controllers. Other specialities illustrated are controllers for A.-C. and D.-C. lifts, and suitable for car-switch or push-button operation, gear for the automatic and remote control of air-compressors, hydraulic accumulators, pumps, printing-presses and machine tools, A.-C. lift brakes, &c. All the contacts are of the individual lever type positively and separately operated, and there are no sliding contacts. Some hand-operated switches with quick make and break are also listed.

"METALIK" LAMPS

WE have from time to time referred to the various new and modified patterns of the "Metalik" lamp supplied by Messrs. G. M. Boddy & Co. (15 Gray's Inn Road, London), and we now have a further improvement to chronicle. In ELECTRICAL ENGINEERING, October 27th, 1910, p. 684, a description was given of a special lamp adapted for factories, &c., where there is much vibration. The composition of the filament itself is the same as that of the original "Metalik" filaments, and the efficiency is as high (namely, 1·25 watts per candle), but the filament is arranged in a larger number of shorter loops, which results in a much stronger lamp. As shown in the figure, each loop is supported at the bend by a hooked wire with a wave or loop at its centre to give increased elasticity. This lamp was then only supplied for pressures up to 125 volts, but can now be obtained in the high-voltage sizes, so that mill-owners and others, whose premises are wired for 200 or 240 volts, can now use the anti-vibration lamp.

THE "METALIK" ANTI-VIBRATION LAMP.

"Metalik" lamps are notable for their long burning lives. Results of life and efficiency tests carried out on these and other lamps by Mr. F. H. R. Lavender, and described by him in a Paper read before the Birmingham Section of the Institution of Electrical Engineers, were given in ELECTRICAL ENGINEERING, Vol. V., p. 1047, while further life curves of "Metalik" lamps were given on p. 1065 of the same volume. These showed that the drop in candle-power during the first 1,000 hours was negligible. The average life of these lamps is, we are informed, well over 2,000 hours, and in some cases very much longer lives have been recorded.

At the firm's showroom in Gray's Inn Road, is an ingenious motor-driven rocking apparatus, which subjects a bar, on which are mounted several "Metalik" lamps, to successive jerks. The lamps are not affected by this severe treatment, thus demonstrating the toughness of the filaments. Recently, the firm received a letter from the manager of a provincial theatre, stating that two 50 c.p. "Metalik" lamps had been in constant use for three years, the estimated burning hours being between 8,000 and 9,000. They had, he wrote, been taken down and cleaned dozens of times without injury.

All these lamps are manufactured by the Philips Metallic Glowlampworks, Ltd.

Aeronautics.—Mr. A. R. Low will deliver a course of eight lectures, together with drawing office work, on "The Design and Calculation of Aeroplanes," at University College, on Fridays, at 5.30 p.m., beginning February 3rd. A visit will be paid to the aviation ground at Brooklands. Further particulars may be obtained from the Secretary of the College.

Electric Fire Signals.—Messrs. Merryweather & Sons, Ltd. (Long Acre, London), have installed an electrically worked syren at the Letchworth Garden City for warning the inhabitants of an outbreak of fire. The syren itself is coupled direct to a small totally enclosed motor, and mounted in a weatherproof casing on the top of a high pole. A fire-alarm push with glass-fronted case is fixed at the base of the pole. The motor is worked from the main supply, the necessary fuses and series resistances being placed in a weatherproof box.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published January 19th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

29,985/09. **Telephone Relay.** S. G. BROWN (London). This specification relates to improvements in the type of relay described in Patent No. 11,135/08, in which the current variations in the secondary circuit are produced by the alterations in length of a minute gap. (See abstract of Mr. Brown's Institution Paper on this relay in ELECTRICAL ENGINEERING, Vol. VI., p. 305.) This patent covers the use of carbon or carbon and metal electrodes at the gap mounted on a vibrating metal strip, which can be adjusted. The length and resistance of the gap are regulated by an electromagnet in the local circuit, which includes the gap. The electromagnet is shunted by a resistance or a capacity, or is surrounded by a copper sheath, in which eddy-currents are set up, to neutralise the self-induction. Four figures.

30,548/09. **Telephone Condensers.** C. CORDES (Magdeburg). Insulating substances of high dielectric capacity are produced from vegetable or animal oils, such as castor oil, by treatment with hydrogen in the presence of a finely divided metal, which acts as a catalyser. Double the capacity for a condenser of given size is claimed as compared with paraffin condensers.

30,566/09. **Motor Starter.** A. H. CURTIS and ADAMS MANUFACTURING CO., LTD. This is a starter of the reciprocating rod pattern, described in ELECTRICAL ENGINEERING, Vol. VI., p. 247, but adapted for automatic or remote control by means of a solenoid or a motor and worm gear. Ten figures.

205/10. **Motor Starter.** W. R. ANSELL (London). A starter for small portable motors has, in addition to the usual stepped resistance, a second set of resistances controlled by another handle or switch for connecting in series so as to adapt the apparatus for working off different supply voltages. Three figures.

1,518/10. **Wireless Telephony.** A. A. JAHNKE and S. C. TATE (San Francisco). A heavy-current transmitter for wireless telephony consists of two iridium-platinum electrodes enclosed in a chamber filled with carborundum granules. One electrode is attached to the main diaphragm. The annular wall of the chamber is of porous material, and alcohol or other volatile hydro-carbon is forced into the chamber through this wall. The evaporation of the alcohol cools the granules. One figure.

7,488/10. **Machine Construction.** CROMPTON & CO., LTD., J. C. MACFARLANE and H. BURGE. A form of construction suitable for small four-pole dynamos and motors consists in making the yoke rectangular and parallel to the armature spindle, so that it forms a support for the bearings. The pole pieces are attached two at the top and two at the bottom, and are readily detached without removing the armature. One figure.

8,167/10. **Enclosed Flame Arc Lamp.** CARBONE ARC LAMP SYNDICATE, LTD. (*T. L. Carbone, Charlottenburg*). This patent covers an improved construction of globe for enclosed flame lamps, as described in specification No. 17,448/09. The lower chamber of the globe opens into long closed tubes, which rise on the outside of the globe, and in which the vapours are condensed. One figure.

9,076/10. **Arc Lamp Carbons.** GEBR. SIEMENS & CO. (Berlin). Carbons for flame arc lamps are impregnated with, or have cores of a mixture of one or more oxides of cerium, lanthanum, didymium, or zirconium, with oxides of calcium, strontium, and barium. A compound of calcium oxide with cerium peroxide is a suitable substance, and the addition of fluor spar tends to prevent hissing of the arc.

23,671/10. **Insulating Material.** C. F. PEIERSON (Schenectady). Fragments of mica are pressed together with an adhesive substance between layers of a yielding material, such as asbestos. Six figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: SIEMENS-SCHUCKERTWERKE GES., 12,483/10.

Dynamos, Motors and Transformers: MAVOR, HOBART, and MAVOR & COULSON, LTD. [System of obtaining variable speeds with polyphase motors] 30,556/09; MISSOTTEN [Automatic control of internal combustion engine generating set] 9,222/10; ADAMS MANUFACTURING CO. (*Cutler Hammer Mfg. Co., U.S.A.*) [Motor control] 17,341/10; SIEMENS-SCHUCKERTWERKE GES. [Reversing polyphase motors] 28,661/10.

Electric Ignition: R. BOSCH, 19,242/10; UNTERBERG & HEMLE [Contact-breaker for magneto system] 22,040/10.

Electrometallurgy and Electrochemistry: BRYNE [Primary cells] 568/10; AKTIEBOLAGET ELEKTROMETALL [Regulating electrodes of smelting furnaces] 12,430/10; A. W. PENROSE & Co. (*Benedict*) [Electro-typing] 16,709/10.

Instruments and Meters: LUCAS, WALMSLEY and WALMSLEY [Apparatus for distributing electricity] 4,115/10; HEADING and WILLIS [Coin-freed meter] 6,902/10; SIEMENS BROS. & Co. (*Siemens & Halske A.-G.*) [Determining direction of equalising currents in A.C. apparatus] 22,224/10.

Switchgear, Fuses & Fittings: BENSTEAD and ARON [Motor-car lamps] 97/10; BEIN [Adjustable support and contact device for electric fans] 212/10; VENNER and GRIESBACH [Time switches] 1,296/10; MIDDLETON and BAKER [Fuses] 13,311/10; SIEMENS-SCHUCKERTWERKE GES. [Fuses] 18,528/10; VIETTE [Bell-call indicators] 18,678/10; HOUSKEEPER [Contact devices for moving conductors] 24,911/10.

Telephony & Telegraphy: BAKER [Electrical transmission of drawings and photographs] 361/10.

Traction: HARDY [Vacuum brakes] 20,584/10; WOODS and GILBERT [Machine for dressing rails] 22,669/10 and 22,670-1-2/10.

Miscellaneous: MORISON [Exhaust steam accumulators] 28,223/09; NEWITT [Commutator grinder] 28,340/09; SIEMENS BROS. & Co. and HIRD [Measurement of thrust of shafts] 28,353/09; CONNOR and WILKINSON [Signs] 510/10; JEVONS and GREEN [Electric welding] 6,553/10; SIEMENS BROS. DYNAMO WORKS and KIEFFER [Automatic non-return valves] 20,090/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: KUNKEL [Machines] 29,941/10.

Incandescent Lamps: SCHILLING [Manufacture of metal filaments] 23,639/10.

Instruments, &c.: BESANCON [Hour meter] 28,884/10 and [Meter mechanism] 28,885/10.

The following amended Specification can now be obtained.

PALMER [Prepayment meter] 10,802/10.

Opposition to Grant of Patents

22,783/09. **Smoke Consumption.** S. O. COWPER-COLES. Opposition has been entered to the grant of this patent. The specification describes a boiler furnace with a lining of refractory material at the rear of the firebridge with means of supplying air to it. Various constructions are illustrated, and an improved means of covering the cross tubes with refractory material is described.

28,210/09. **Advertising Sign.** A. W. LEONARD. This patent is opposed. It covers an electrically-driven and illuminated advertising device in which transparent advertisements are exhibited successively through apertures in a box. The advertisements are brought to rest for a time in front of the apertures, and are only illuminated during this period.

2,983/10. **Tungsten Filaments.** WESTINGHOUSE METALLFADEN-GLUHLAMPENFABRIK GES. (Vienna). The opposition to the grant of this patent has been withdrawn. The specification, abstracted in ELECTRICAL ENGINEERING, Nov. 3rd, 1910, p. 700, describes a process of decarbonising tungsten filaments in a vacuum furnace.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

2,801 of February 2nd, 1897. **Transformers.** A. F. BERRY. This is the fundamental patent covering the construction of the well-known Berry transformer, in which the iron laminations are arranged radially round a centre, so as to form a cylindrical iron shell, the primary and secondary windings being wound one over the other in the annular space between the core and outer members of the shell.

The following are the more important Patents that have become void through non-payment of renewal fees.

Instruments, &c.: R. BELFIELD (*E. M. Tingley and O. B. Shallenberger, U.S.A.*) [Phase-displacing arrangements for meters, etc.] 22,852/97; R. T. and J. G. GLOVER [Prepayment meters] 19,855/01; COMP. ANON CONTINENTALE POUR LA FABR. DES COMPTEURS À GAS [A.C. motor meters] 12,801/03.

Switchgear, &c.: H. LEITNER and R. N. LUCAS [Automatic regulator for train-lighting dynamo] 21,144/04.

Traction: G. GIBBS and H. PEARSON [Construction of motor coaches] 13,176/03; J. T. CADE [Automatic electrical signalling] 15, 737/03; J. W. CROSS [Vacuum brakes] 19,976/05; R. MAW [Braking and starting of electrical vehicles by compressed air] 20,005/05.

Miscellaneous: T. LOWE [Smoke consumption] 22,614/97; S. LAKE [Electric submersible winch for floating stranded vessels] 20,840/98; S. C. DAVIDSON (Sirocco Works) [Mounting of electric-fan casings] 21,821/02; E. BACHELET [Electro-medical apparatus] 21,138/04; I. H. PARSONS [Electric clock mechanism] 19,906/05; H. HAWTHORN [Fire alarms] 20,051/05.

OSRAM, BODDY, AND PHILIPS LAMPS

Result of Patent Action: An Osram Success: Important Agreement

PREPARATIONS for an important patent action, to determine whether or not the lamps manufactured by Philips' Metallic Glowlampworks, of Eindhoven, Holland, and sold in this country by G. M. Boddy & Co., infringed the patents owned by the manufacturers of the Osram lamp, have been proceeding for several months. The Osram Lamp Works, Ltd., had retained the services of two of the leading counsel who are particularly eminent in patent cases, viz., Sir Alfred Cripps, K.C., and Mr. A. J. Walter, K.C., and also Mr. Colefax and Mr. Lunge, and as expert witnesses Sir James Dewar, Dr. Liepmann, Mr. James Swinburne, and Dr. Silvanus P. Thompson; while for Messrs. Boddy & Co., Mr. W. R. Bousfield, K.C., Mr. H. Terrell, K.C., Mr. H. Fletcher Moulton, and Mr. Kenneth Swan had been retained as counsel, and Prof. H. Ballantyne, Dr. Otto Hehner, and Mr. C. O. Bastian as expert witnesses.

On Monday last, however, it was announced in court, before Mr. Justice Parker, that an agreement had been arrived at between the parties, and that the defendants, Messrs. G. M. Boddy & Co. had agreed to judgment being entered against them, with costs.

We are in a position to state that the terms of the arrangement between the parties are mainly as follows: The Philips Metallic Glowlampworks have agreed to take a licence under the two patents in question and to pay the Osram Lamp Works, Ltd., a substantial royalty upon all lamps which they import into the United Kingdom. All these lamps, whether sold directly by Messrs. Philips or through their agents, are to be marked "Philips, U.K." A scale has been fixed by which the number of lamps imported by the firm year by year is to be limited, although the numbers which have been fixed will permit of a substantial business being done in them, so that undoubtedly a fair proportion of the lamps produced at the large Philips works at Eindhoven will still come to this country. In addition to these restrictions, a clause has been included to control prices and discounts, and thus to prevent price-cutting. The royalties paid will be chargeable on all lamps imported since January 1st, 1911, and up to the year 1918, towards the end of which the fundamental patent will expire. The claim for retrospective royalties previous to the beginning of this year has been waived.

We understand that it is not the intention of the General Electric Co., Ltd. (who are the selling agents of the Osram Lamp Works, Ltd.), to increase prices above the present figures, but, on the contrary, prices of Osram lamps will be reduced gradually, as hitherto, as the cost of production diminishes and the demand develops. In fact, it is not unreasonable to expect that the price of sizes of 100 watts and upwards will shortly be lowered, for the increased output of these is rendering it possible for special machines to be set aside entirely for the glass-blowing work on these sizes.

The two patents upon which the action was brought are No. 23,899 of 1904 and No. 16,503 of 1907.

No. 23,899 of 1904 granted to Dr. A. Just and F. Hanaman, of Vienna, describes a process of manufacturing filaments of pure tungsten by mixing finely divided tungsten or tungsten compounds such as tungstite, tungstic acid, or tungstic sulphide with an organic binding medium such as collodion, or a solution of cellulose in chloride of zinc or cupreous ammonia oxide. The filaments squirted from the resulting paste are then carbonised (in some cases after denitration), and the carbon is then removed by passing current through the filament and raising it to a high temperature in an atmosphere of steam and hydrogen. The carbon is oxidised to form carbonic oxide, and a filament of pure tungsten is left. The filaments are then rendered uniform by submitting them to the action of current in an atmosphere of volatile tungsten compounds in the presence of a large quantity of hydrogen, whereby the tungsten deposited equalises the filaments.

This patent was published in full in ELECTRICAL ENGINEERING of Sept. 9th, 1909, after the grant of an amendment by the Comptroller.

No. 16,503 of 1907, granted to Deutsche Gasglühlicht Aktiengesellschaft (Auergesellschaft), relates to the leading-in wires and the wires which support the filaments. A platinum wire can be successfully fused round the end of the filament, but when nickel wire is used, frequent breakages occur owing to the tungsten forming an alloy with the nickel, which melts in the arc, and thus causes a reduction in the section of the filament near the joint. When copper wire is used there is difficulty in preventing the filament end from escaping out of the fused globule of copper before the latter has solidified. According to this invention, a wire of two metals, in the form of an alloy, or of two wires twisted together, or a wire of one metal coated with the other, is employed, for example, copper or silver wire coated with nickel or iron. The first claim of this patent is, broadly, for "attaching tungsten filaments to the fused ends of current leads, in electric glow-lamps, wherein said leads consist of two different kinds of metal, one of which forms an alloy with tungsten, whilst the other does not."

Although the Philips lamps will now be made under licence, and it is an open secret that definite agreements for "pooling" patents have been made with the British Thomson-Houston Co., the Sunbeam Lamp Co., and the Westinghouse Co., and possibly one other whose name is now familiar to our readers, we are waiting with interest to see whether there will be further developments of the patent situation; for the Osram people, in view of their victory in the present case, may, as they have already cleared their decks for action, use their formidable armament against other manufacturers. In addition to the two patents selected in the present case, the Osram Lamp Works, Ltd., own a large number of others, and these two are by no means the only ones relating to processes in metallic filament lamp manufacture to which they attach importance. Of these, two patents known as the "weighting" and "forming gas" patents respectively are particularly worthy of mention.

No. 8,563 of 1907, granted to the Deutsche Gasglühlicht Aktiengesellschaft (Auergesellschaft) of Berlin, describes a method of ensuring that the contraction which takes place when a filament squirted from a paste is sintered, shall be uniform along the filament. If there is a lack of uniformity, there is a danger of the spots at which the resistance is higher attaining a higher temperature, and so shortening the life of the filament. To prevent these bright spots being formed, the filament is subjected to a slight tension during the process of sintering by hanging a small weight such as a tungsten hook from the filament at the bend of the loop. This not only ensures uniform contraction, but gives the sintered filament the required pointed shape.

No. 18,622 of 1906, granted to P. M. Justice, London, and communicated by the Deutsche Gasglühlicht Aktiengesellschaft (Auergesellschaft), describes a process for removing the carbon from the carbonised filaments produced by the method described in 23,899/04, referred to earlier in this article. Instead of the carbon being oxidised, it is carried away in the form of a compound, not with oxygen, but with nitrogen and hydrogen. The carbonised filament is caused to incandesce in an atmosphere of ammonia (or a mixture of hydrogen and nitrogen), and the carbon is carried away in the form of cyanogen and hydrocyanic acid. This method is easier to carry out than the steam-hydrogen method, and there is no danger of the tungsten filament being attacked.

Telegraph Traffic and Movements of Cable Ships.—On 17th inst. the cable between Dakar and Konakry was interrupted, and on the 18th that between Hongkong and Macao broke down. —The *viâ* Hanekine route was restored on the 20th inst., and the El Arich route on the 22nd inst.—The Hongkong-Macao section was restored on the 21st inst.—The French company have still to complete the repair of the Cape Haiti-Puerto Plata section.—The French Cable Company's steamer, the c.s. *Contre Amiral Caubet*, was less busy than her sister ship in the West Indies, the c.s. *Pouyer-Quertier*, for she did not leave port during December last. The c.s. *Minia*, of the Anglo-American Telegraph Co., was engaged on a repair of the 1873 cable off Heartscontent, Newfoundland, and returned to Halifax, N.S., on Dec. 29th.

Important Notice to the Public.

METAL FILAMENT LAMPS.

IN THE HIGH COURT OF JUSTICE, on the 23rd day of January, 1911, before the Hon. Mr. Justice Parker, an injunction was granted in favour of the Osram Lamp Works restraining G. M. Boddy & Co., their agents, etc., from infringing Letters Patent No. 23899 of 1904, and No. 16503 of 1907, under which amongst other Letters Patent

OSRAM LAMPS

are manufactured.

The Trade and the Public are hereby warned against selling or using infringing lamps.

The General Electric Company, Ltd.,

beg to notify the Public that no possible risk or liability can be incurred by the Public in purchasing or using Osram Lamps or lamps sold under license from them.

OSRAM LAMPS

can be obtained by the Public at all Electrical Contractors, Ironmongers, Stores, etc.

THE TRADE WILL BE SUPPLIED BY THE DEPOTS OF

The General Electric Company, Ltd.,

LONDON, MANCHESTER, GLASGOW, BIRMINGHAM, NEWCASTLE, CARDIFF, Etc.

Hosted by Google

LOCAL NOTES

Beckenham: *Sales Department.*—Showrooms have been opened by the Electricity Committee at the corner of High Street and Manor Road. Demonstrations of electric cooking are given daily. The local contractors will receive the profits of any sales effected, after a small percentage has been deducted to assist in paying the establishment charges.

Berlin: *Trolley Omnibuses.*—A trackless trolley line is proposed at Gross Lichterfelde on the Lloyd-Köhler system, which is already in use at Bremen.

Coventry: *Tramway Purchase.*—The Tramway Company is to be given notice requiring them to sell their undertaking to the Corporation on agreed terms, or, failing agreement, by arbitration.

Emsworth (Hants): *Electric Lighting.*—The question of adopting public electric lighting has been referred back to the Lighting Committee.

Greenock: *Disposal of Electricity Profits.*—The Scottish Office has modified its request that all the profits of the electricity undertaking should be transferred to reserve fund. It is now agreed that the sum to be paid into reserve fund each year, shall be increased from £1,000 to £1,500.

Japan: *Water-power Schemes.*—The *Board of Trade Journal*, quoting from a report by the British Commercial Attaché at Yokohama, states that a Government Commission has been established with the object of promoting the development of water-power schemes, and preventing the water-power resources of the country from being exploited by financially unsound individuals or corporations.

London: *Islington: Municipal Wiring.*—The members of the Lighting Committee of the Borough Council, who resigned on the Council refusing to allow the Electricity Department to do wiring work, have withdrawn their resignations. The Committee will report on the question of electricity *v.* high-pressure gas for the public lighting.

Stepney: Periods for Repayment of Loans.—The Finance and Parliamentary Committee report negotiations with the London County Council with regard to closing the account for loans borrowed for a period of 42 years for the electricity undertaking, and to substitute varying periods for different portions of the machinery. This plan is to be adopted, subject to certain conditions.

Manchester: *Tramwaymen's Hours.*—Negotiations between the Tramway Committee and the Tramwaymen's organisation in Manchester are still continuing, but no definite decision has been come to with regard to sending the matters in dispute to arbitration. Before agreeing to this course, the Tramway Committee require certain guarantees from the Men's Union.

Middlesex: *Tramway Centre Poles.*—Many hundreds of residents in Finchley have petitioned the District Council in favour of removing the tramway centre poles in the Great North Road on the ground that they have resulted in the loss of several lives.

Morocco: *Telephones.*—It is stated that the Moorish Government is to purchase the Tangier telephone undertaking, which is at present worked by a Spanish company.

Nelson: *Proposed Tramways.*—A scheme for running tramways between Nelson and Colne is under consideration. If the scheme is carried through, it will be undertaken by the Colne & Trawden Light Railway Co.

New Zealand: *Water-power Development.*—The Board of Trade have been supplied with a few copies of the reports by the Government Engineer-in-Chief on utilising water-power in New Zealand, and also by Mr. Laurence Birks on the same subject. Copies may be obtained at 73 Basinghall Street, London, E.C.

Sheffield: *New Car Sheds.*—In order to accommodate the increase in tramway rolling stock, new car sheds have been erected in Shoreham Street at a cost of about £26,000. There is accommodation for about 100 cars.

West Hartlepool: *Tramway Purchase.*—An arbitration took place in London last week with regard to the purchase by the Corporation of the Foggy Furze and Park tramway routes. Mr. C. A. King was arbitrator, and Mr. C. C. Hutchinson, K.C., and Mr. Tyldesley Jones appeared for the Tramway Company, whilst Mr. Balfour Browne, K.C., and Mr. Clode represented the Corporation. The total claim by the Tramway Company amounts to £20,871 10s., whilst the estimates of the Corporation witnesses amount to between £8,000 and £9,000. The arbitrator reserved his award.

Willesden: *Rating Appeal.*—The Metropolitan Electric Supply Company's property in Willesden, which originally stood at £17,452 gross and £11,635 rateable value, was recently raised by the Assessment Committee to £20,000 and £13,000 respectively. The Company appealed last week at the Middlesex Quarter Sessions against the rateable value, and succeeded in getting this reduced to £8,900.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Edinburgh.—A loan of £75,000 has been sanctioned for electrical extensions.

Finland.—An application has been made on behalf of a London firm for a concession to use water from the Saima Lake for supplying electrical energy in St. Petersburg and Helsingfors, and for working the Finnish railways by electric traction. According to a Reuter telegram, it is proposed to carry the water by means of a tunnel a mile long to Kuurmanjoki, where a generating plant with a capacity of 168,000 h.p. is to be erected. The capital involved is said to amount to over £1,000,000.

Greenock.—An additional turbo-alternator is to be installed at the Electricity Works.

Ipswich.—A 600-kw. or 750-kw. continuous-current turbo-alternator, with surface condensing plant, is required by the electricity department. Particulars from the Chief Electrical Engineer, and tenders by February 9th.

India.—Messrs. Alfred Dickinson & Co., of Birmingham and London, who are the consulting and constructional engineers in connection with the Bombay water-power scheme, are preparing specifications. The preliminary hydraulic works have already been commenced, the contract having been given to Messrs. Pauling & Co., of Westminster.

The Calcutta Electric Supply Corporation require H.T. and L.T. substation switchboards. Particulars from the Secretary, Salisbury House, London Wall, London.

Leek.—A Diesel engine and D.C. dynamo is required for the electricity works. Particulars from the Electrical Engineer, and tenders by February 9th.

London: *St. Pancras.*—A loan of £3,997 has been sanctioned for electrical extensions.

Luton.—A loan of £2,396 has been sanctioned for an additional boiler, economiser, &c., at the Electricity Works.

Mansfield.—Additional plant is to be installed at the power house.

Mexico.—The *Board of Trade Journal* announces that a 20 years' concession for the utilisation of water from the River Cuautitlan, in the State of Mexico, for hydro-electric purposes, has been granted to Jose Luis Requena. Work must be begun within 24 months, and completed within seven years. The concessionaire may set up telegraph and telephone lines, and may build bridges for his private needs. All the machinery and apparatus required for the work may be imported free of duty.

Netherlands.—An electric power station is to be established in the East Friesland district by the Municipality.

Rawtenstall.—An extension to the high-tension switchboard at the electricity works is required. Particulars from the Electrical Engineer, and tenders by February 1st.

South Africa.—The Standerton Council, says the *British and South African Export Gazette*, are about to spend £5,000 upon electric lighting.

Swindon.—The Electricity Committee recommend an expenditure of £3,659 on a new battery, and £6,637 on new generating machinery.

Uruguay.—The *Board of Trade Journal* announces that a 25 years' concession for electric lighting in the town of Melo has been granted to Messrs. Silveria Hermanos, and a 20 years' concession with regard to the town of Trinidad to Messrs. Carbonell & Co.

Wakefield.—The electricity department require an 800-kw. alternator. Particulars from the Electrical Engineer, and tenders by February 14th.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

GREATER LONDON.

Rebuilding of the Cavendish Rooms, 51/55 Mortimer Street, W.

Cinematograph hall in Herne Hill Road. Messrs. H. Wakeford and Sons.

Buildings in Halpin Place, Walworth.

Buildings on eastern side of Stamford Hill, Hackney.

Extensions to South Eastern District Post Office. Architect, Mr. J. Ruthford, 22 Carlisle Place, S.W.

Gymnasium and Art Room at the Avery Hill College, Eltham. L.C.C. Architect's Department, 19 Charing Cross Road, W.C.

PROVINCES.

Aldershot.—New Secondary School. Architects, Kingham & Kingham, Bank House, Grosvenor Road, Aldershot.

Birmingham.—Extensions to school in Station Road, Harborne.

Bristol.—New Music Hall. Mr. Oswald Stoll.

Darlington.—Elementary School in Reid Street.

Edinburgh.—Electric theatre at 18 to 20 Nicholson Street.

Farnham.—Alterations and additions to Drill Hall premises, Bear Lane. Architects, Robinson & Rhodes, 8 New Court, Carey Street, London, W.C.

Hastings.—Electric lighting at Workhouse.

Hereford.—Secondary School in Widemarsh Street.

Heywood.—Theatre in Market Street.

Leek.—New schools at Baddeley Green.

Liverpool.—Proposed Accident Hospital at Garston.

Newmarket.—New Technical School.

Northampton.—Secondary school for girls.

Wakefield.—Headquarters for West Riding Constabulary.

York.—New lecture theatre at the Museum.

MISCELLANEOUS

Australia.—Tenders are invited by March 8th by the Deputy Postmaster-General at Brisbane for measuring instruments. Particulars from 73 Basinghall Street, London, E.C.

Beckenham.—The street lighting of the Shortlands district will be changed over from gas to electricity as from April 1st.

Glengarnock.—The Glengarnock Iron & Steel Co., Ltd., are to carry out some further public lighting in Glengarnock.

Halifax.—The Corporation require a twelve months' supply of various stores, including lighting fittings, electrical accessories, cable, &c. Particulars from the Town Clerk, and tenders by February 6th.

Ireland.—The Midland Railway Co. of Ireland invite tenders for general stores for twelve months, including telegraph wire, batteries, &c. Tenders by February 2nd.

Leeds.—The Electricity Committee require 1,500 A.C. wattmeters. Tenders by February 16th.

TENDERS RECEIVED AND ACCEPTED

Haslingden.—The tender of Messrs. Simpson Bros. has been accepted at £856 10s. for the electric lighting of the Pike Law Infirmary and other Union buildings.

Limerick.—The tender of Messrs. Johnson & Phillips, Ltd., at £198 has been accepted for the electric lighting of the technical schools, and for an installation of telephones at £23 15s. The tenders in the first case ranged from £198 to £424, and for the telephones from £23 to £44.

London: *County Council.*—The following tenders have been received for electric motors and a 25 kw. motor generator for No. 23 Belvedere Road:—Lancashire Dynamo and Motor Co., Ltd., £581 10s. (motor generator, £168); British Thomson-Houston Co., Ltd., £602 12s. (motor generator, £173); Electric Construction Co., Ltd., £741 10s. (motor generator, £207 10s.); Dick, Kerr and Co., Ltd., £788 (motor generator, £223 5s.); and British Westinghouse Electric and Manufacturing Co., Ltd., £419 18s. (motors only). The tender of the Lancashire Dynamo and Motor Co., Ltd., has been accepted.

The following tenders were received for the wiring at 23 Belvedere Road:—Edison and Swan Co., £385 15s., less 2½ per cent.; General Electric Co., Ltd., £396; Veritys, Ltd. (incomplete), £301. The first named tender has been accepted.

The tender of the Sunbeam Lamp Co., Ltd., has been accepted for a 12 months' supply of electrical fittings, and that of Messrs. Hoopers Telegraph Works, Ltd., for cables and wires.

Hackney.—The tender of the Private Telephone Co., Ltd., at £57 15s. has been accepted for an installation of telephones in the "A" and "B" pavilions at the High Street, Homerton, Infirmary.

Southend.—The tender of the Lancashire Dynamo & Motor Co., Ltd., has been accepted at £1,696 for a battery booster plant.

Messrs. Siemens Bros. Dynamo Works, Ltd., have obtained the contract to supply Tantalum lamps for 12 months for the Royal Mail Steam Packet Company for ship lighting.

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £57 10s. to £58 per ton (last week, £58 to £58 10s.).

Business for Sale.—An electrical installation business is for sale on exceedingly moderate terms. (See an advertisement on another page.)

Western Electric Co.'s Branch Offices.—The Western Electric Co., Ltd., have opened branch offices at 115 Colmore Row, Birmingham; Standard Buildings, City Square, Leeds; and 2 Bank Buildings, Cardiff, where representatives will give personal attention to inquiries for cables, telephones, and electrical supplies in the surrounding districts.

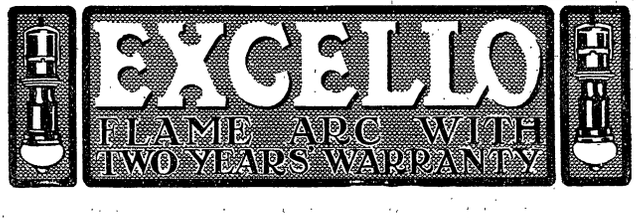
Canada.—Inquiries have been received at the office of the High Commissioner for Canada (17 Victoria Street, S.W.) from a correspondent in New Brunswick for the names of electrical manufacturers in Great Britain using amber mica. We are also informed that a London firm wishes to act for Canadian shippers of mica and asbestos, desiring to develop trade in Switzerland, Germany, Austria, and other Continental countries. Particulars from 73 Basinghall Street, E.C.

APPOINTMENTS AND PERSONAL NOTES

Mr. H. M. Hobart, the well-known consulting engineer and expert in dynamo design, and the author of many widely read treatises on electrical engineering, is leaving England on March 7th to join the permanent staff of the General Electric Co. of America as a consulting engineer. On Saturday last, some 75 friends assembled at a farewell dinner in London under the chairmanship of Mr. H. F. Parshall, and a presentation was made to Mr. Hobart of a silver cup on which the names of the donors were engraved. Mr. Hobart first came to England in 1895 to join the B.T.-H. Co., and in 1900 went to Berlin to the Union Elektricitäts Gesellschaft. Since 1903 he has practised in London, and was retained by several leading manufacturers of electrical machinery in a consultative capacity.

We are requested to announce that the engagement of Mr. M. F. Part, with the Hart Accumulator Co., Ltd., as traveller, terminates on December 31st.

Junior draughtsman required in London office of well-known firm of engineers (see an advertisement on another page).



Mr. J. W. Dugdale, General Manager of the Ashton Corporation Tramways, has been appointed to succeed Mr. L. Slattery as General Manager at Oldham.

The salary of Mr. E. Lunn, Electrician-in-Charge of the Huddersfield electricity station, has been increased from £156 to £170.

Mr. A. F. Clement, Telegraph Engineer to the North British Railway Co., has retired under the age-limit. He is succeeded by Mr. David Wells, his assistant for many years past.

Mr. Lewis Slattery, General Manager of the Oldham Tramways, who has been appointed to the L.C.C. Tramways staff, has been presented with a case of cutlery by the tramway employees.

Palladium Stage Lift.—In our description of the electrical equipment of the Palladium Theatre on page 30 of last week's issue, the stage lift was, by an error, referred to as having "Eastman" control. The entire lift, with the push-button control gear, was installed by the Easton Lift Co., Ltd. (Express Works, Short Street, Southwark, S.E.).

Hosted by Google

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

East London Railway Co. The directors' report for the six months to October 31st states that the electrification of the line is still engaging the attention of the Board, and that a survey by a leading electrical company is in course of progress. When this survey is completed, a report will be made as to the approximate cost of reconstruction for electric traction. At the meeting on Tuesday, Lord Claud Hamilton said it had been decided that it was impossible to adopt the single phase system owing to the height of the tunnels. It really amounted to adopting the third rail system, as used upon the other underground railways in London, but the directors were not masters of the situation, either as regards their liberty of action, or the raising of capital. When the survey of the line is completed, the matter will be placed before the lessee companies, and he thought that the Metropolitan and possibly the District Railway Companies would be favourable to assisting in finding the necessary capital.

Metropolitan Railway Co.—The total receipts for the December half-year amounting to £403,169, show an increase of £12,413, whilst the expenditure of £200,147 has decreased by £5,505. A dividend at the rate of 1½ per cent. per annum is recommended upon the ordinary stock, carrying forward £9,498.

Lanarkshire Tramways Co.—After placing £8,500 to depreciation, a dividend at the rate of 6 per cent. per annum for the December half-year is declared upon the ordinary shares, with £1,499 carried forward.

City & South London Railway Co.—After transferring £1,500 to renewal fund, and meeting the 5 per cent. preference dividend, a dividend at the rate of 1¾ per cent. per annum is recommended on the ordinary stock for the December half-year, carrying forward £1,788.

Aron Electricity Meter.—Subscriptions are being invited for an issue of £100,000 five per cent. first mortgage convertable debentures at 97. The debentures will be repayable at 105 by means of a cumulative sinking fund of 3 per cent. beginning April 1st, 1914.

Minnesota & Ontario Power Co.—Subscriptions have been invited for $500,000 six per cent. first mortgage gold bonds. The company is a general trading concern, besides dealing with the supply of electrical power.

London, Brighton & South Coast Railway Co.—The report for the December half-year calls attention to the growth in receipts due to a revival of the third-class traffic, in which there has been an increase of nearly three millions in the number of passengers carried as compared with the corresponding period of last year, a result largely due to the inauguration of electric traction. The capital expenditure during the half-year amounted to £115,712, of which the most important item has been the expenditure upon converting the lines between London and the Crystal Palace to electric traction.

Wireless Telegraph Notes.—Professor Edouard Branly, the well-known wireless telegraph pioneer, has been appointed to the French Academy of Sciences. It will be remembered that there has been some considerable discussion as to whether Madame Curie should be elected.

According to the *Morning Post* Birmingham correspondent, the International Wireless Telegraph Conference, which was to have been held in London this summer, has been postponed until next year.

SUMMARY

Our monthly supplement on Electrical Engineering in Mines is included in this issue. It opens with an abstract of a Paper on electric power in collieries by Mr. J. Miller, expressing a preference for three-phase working, and emphasising the advantages of the bar type of coal-cutter. A report is also given of a Paper recently read before the Institution of Mechanical Engineers describing the electrical coal hoists at Clydebank. Other articles include a description of the electrical equipments of an eastern tin mine and a New Zealand coal mine. A report of a Paper on mining switchgear is also given, and the electrical mining patents published during the month are reviewed.

Two interesting Papers on high-tension transmission were read at last Thursday's meeting of the Institution of Electrical Engineers. One by Mr. W. T. Taylor and the other by Messrs. R. Borlase Matthews and C. T. Wilkinson. In both Papers the latest practice in America, where voltages up to 110,000 are in use, was described. Special attention was drawn to the suspension type of insulator and the use of flexible steel towers. Mr. D. C. Jackson (President of the American Institute of Electrical Engineers) opened the discussion. (Page 57.)

A Paper was recently read by Mr. P. V. Hunter before the Newcastle Local Section of the Institution of Electrical Engineers on the design of sub-stations, especially as regards the arrangement of the buildings to contain the plant. (Page 68.)

A system of temperature measurement especially suitable for cold storage rooms consists of a galvanometer reading direct in degrees Fahrenheit, and connected with a source of E.M.F. and resistance coils in the different rooms. (Page 59.)

Among the specifications published by the Patent Office on Thursday last, was one by H. A. Mavor and H. M. Hobart for a variable-speed polyphase driving gear, in which variable pole motors are supplied with current of different phase-numbers and frequencies. Siemens-Schuckertwerke Ges. have patents for the ventilation of flame arc lamps, for cartridge fuses with main and long auxiliary fuses in parallel, and for a method of avoiding sparking when reversing three-phase induction motors. A patent by Mr. S. Z. de Ferranti covering the use of a gland round the spindle of mercury-motor meters expires to-morrow after the full life of fourteen years. (Page 60.)

A novel arc lamp on the principle of the Jablochkoff candle, only self-starting, is being brought out. (Page 61.)

A discussion on systems of wiring was held at the last meeting of the Dublin Section of the Institution of Electrical Engineers. Casing and lead-covered wire were, on the whole, generally preferred to conduit. (Page 61.)

The London County Council recommend the Board of Trade not to grant the Bermondsey Council an Electric Lighting Order in competition with two

electric supply companies.—Newport Ratepayers' Association have threatened litigation in respect of the finances of the electricity undertaking.—Glasgow Tramways Committee recommend action being taken to secure that the tramways shall be assessed upon one-fourth of their rateable value.—Trolley 'buses are being suggested for parts of Dundee.—An action has been taken in Stoke-on-Trent in respect of alleged vibration from electrical machinery at a cold storage works. (Page 62.)

A 250 KW. motor generator is required at Barking; a number of telephone switchboards in Australia; tramway rails and fishplates in Birmingham; and electrical stores at Salford and Blackburn. Loans are proposed as follows: Dublin, £125,000; Bedford, £22,837; Doncaster, £12,000; Hastings, £2,803; and Stepney, £3,060. Glasgow Corporation have acquired land for the erection of a new generating station. (Page 62.)

A NEW arrangement has been entered into under which Edmundsons Electricity Corporation will manage the business of the Urban Electric Supply Co. The question of greater speed upon the City & South London Railway is under consideration. There was a deficiency of £3,903 upon the past half-year's working of the Great Northern & City Railway Company. A dividend of 10 per cent. is declared by the St. James & Pall Mall Electric Light Company, and 6 per cent. by the National Telephone Company. (Page 64.)

The G.B. System in the Mile End Road.—Before Lords Justices Vaughan Williams, Farwell, and Kennedy, in the Appeal Court last week, the appeal of Sir John Benn against the judgment for £12,000 damages in respect of certain statements made concerning the G.B. surface contact system in the Mile End Road was mentioned. Sir John Benn has consented to pay £250 into Court as security for costs of the appeal, and the Pay Office had refused to accept that sum without an Order of the Court. The Order was granted.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, FEBRUARY 2ND.

Institution of Electrical Engineers.

7 for 7.30 p.m. Annual dinner at Hotel Cecil.

MONDAY, FEBRUARY 6TH.

Society of Engineers.

7.30 p.m. At Institution of Electrical Engineers, Victoria Embankment. Presidential address by Mr. D. A. Symons.

TUESDAY, FEBRUARY 7TH.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. At Municipal School of Technology. "Wireless Telegraphy," by A. K. Bentley and B. Hoyle.

WEDNESDAY, FEBRUARY 8TH.

Institution of Electrical Engineers: Birmingham Section.

7.30 p.m. At the University. "The Electrical Undertaking of the Birmingham, Tame, and Rea District Drainage Board," by L. F. Mountfort.

Association of Mining Electrical Engineers: Newcastle Branch.

7.30 p.m. At Armstrong College. Discussion on Design of Induction Motors for Haulage, Pumping, and Coal-cutters, and, time permitting, "Electricity in New South Wales Collieries," by E. K. Scott.

THURSDAY, FEBRUARY 9TH.

Institution of Electrical Engineers.

8 p.m. At Victoria Embankment. Adjourned discussion on "Long Distance Transmission of Electrical Energy," by W. T. Taylor, and "Extra High Pressure Transmission Lines," by R. Borlase Matthews and C. T. Wilkinson.

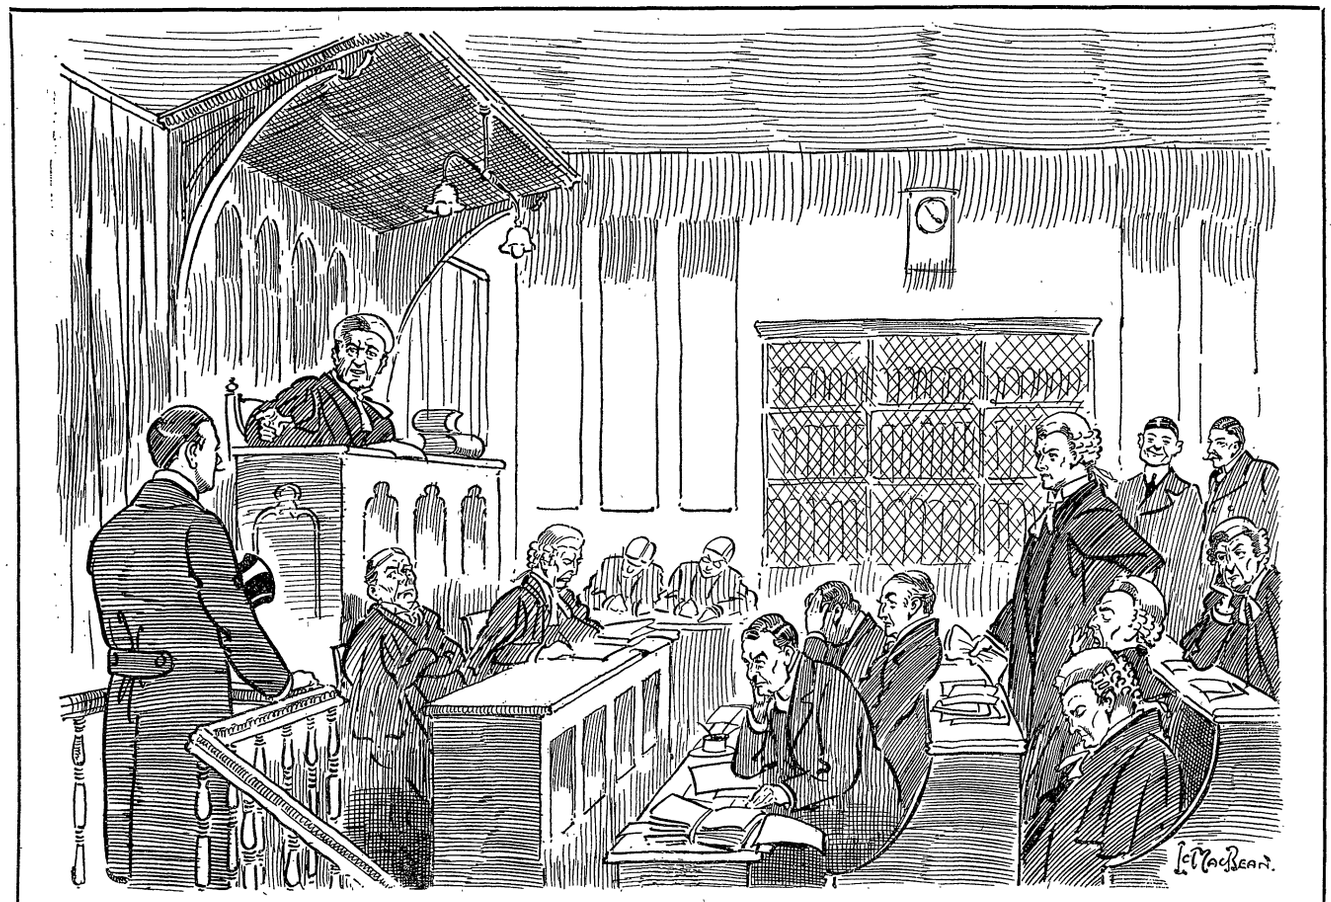
Institution of Electrical Engineers: Dublin Section.

8 p.m. At Royal College of Science.

FRIDAY, FEBRUARY 10TH.

Institution of Electrical Engineers: Yorkshire Section.

6.30 p.m. Annual dinner at Hotel Metropole, Leeds.



SATURDAY, FEBRUARY 11TH.

Institution of Electrical Engineers: Glasgow Section.

7 p.m. Annual Smoking Concert at the Grosvenor.

Junior Institution of Engineers.

6.30 for 7 p.m. Annual dinner at Hotel Cecil.

JUDGE (*to Witness in a Highly Technical Case*): We have been hearing a good deal during the last three days about the rating of motors. I am not sure that I have grasped the exact meaning of the term. Would you mind explaining to me what are the precise conditions which, in ordinary circumstances, would cause a motor to rate?

ELECTRICAL ENGINEERING

IN

MINES

Correspondence on any of the subjects dealt with in this Supplement is cordially invited from our Readers.

The Editor is willing to insert letters over a *nom de plume*, but Correspondents should send their full names and addresses in all cases.

Letters should be addressed, "THE EDITOR, ELECTRICAL ENGINEERING, 203–206 Temple Chambers, London, E.C.," and should reach this office by the 21st of the month.

Correspondents are requested to write on one side of the paper only.

ELECTRIC POWER IN COLLIERIES

A PAPER with the above title was read before the Rugby Engineering Society by Mr. J. Miller on January 19th. In the author's opinion, it is generally more profitable to instal generating plant at the colliery, but if the load consists mainly of haulage, with little pumping and ventilation, the load factor may be very low indeed, and the plant be running at low efficiency, so that it may be cheaper to take power from a supply company. The author gave figures for a 250-kw. colliery set, which gave a total output of some 25,000 units per month. The capital charges amounted to 0·287d. per unit, and the running costs to 0·438d. per unit, giving a total of 0·725d. per unit. These figures refer to a period when the set was only about a quarter loaded. Power was originally taken from a local supply company at the price of one penny per unit.

The author thinks that only the alternating-current system will be used extensively in collieries in the future, giving as his reasons the greater attention required by D.-C. motors, the advantage of being able to use oil-switches with A.-C. apparatus, and the ease and economy of A.-C. transmission at high pressure. He favours generation of three-phase current at a pressure of 3,300 volts, at which pressure pump and haulage motors could be supplied, while motors near the coal-face would be worked at 500 volts. For the prime-mover, he advocates high-speed reciprocating engines, except where a large quantity of exhaust steam is available, in which case the installation of an exhaust steam turbine is advisable.

For distribution in the workings, the author favours armoured cables down the shaft, supplying a switchboard of the ironclad cellular pattern at or near the pit-bottom. The cables along the roads should also be armoured, and should be hung from wood props by pieces of cord, which will break if there is a fall of roof and allow the cable to fall. The armouring must be efficiently earthed and bonded throughout. Earthing at each individual machine by burying a copper plate in puddled clay has been found satisfactory, but earthing on the surface is probably the safest method. In connection with the question of earthed or insulated neutral, the author points out that the neutral must be earthed if the supply is from a company's mains without an intermediate transformer, as an earth on one phase in one colliery following on an earth on another phase elsewhere may have serious consequences. The possibility of an increase of pressure across the remaining two phases, if one goes to earth in an insulated system, is a serious element of danger, but many colliery engineers still prefer the insulated system. A leakage indicator should be used in all installations, and the leakage current should not exceed one milli-ampere per ampere of the supply. The author then briefly described the B.T.-H. Co.'s system of protection devised by Mr. E. B. Wedmore, and described in ELECTRICAL ENGINEERING, June 2nd, 1910, p. 356.

Pumping methods, continued the author, have undergone a radical change by the introduction of electric power. For underground work, reciprocating pumps of the three or four ram type are employed, as they can be constructed to pump against any head. Squirrel-cage motors can be used, as these pumps can be started light. Turbine pumps require less space and cost less, and are used where the head is constant and not too great. At the Cowie Colliery, Stirlingshire, turbine pumps aggregating 400 h.p. and arranged in three stages have recently been installed by Mather & Platt at a cost, including pipes, of about £1,000, to replace old reciprocating pumps operated with beams by a steam engine. The top lift pump discharges 900 gallons per min. against a head of 144 yards. Electrically-driven turbine pumps of the self-contained vertical spindle pattern are invaluable for sinking operations, one great gain being the elimination of steam losses due to leaky pipe-joints.

Turning to coal-cutters, the author referred to the possibility of working small seams with them without producing an excessive percentage of small coal. The disc machine, used chiefly in long-wall working, where the coal is strong, must be able to start up with more than full load torque, and therefore a wound rotor was essential for A.-C. machines. The bar machine is probably the best type for general use. It is less liable to be held up by coal falling on it, and has the great advantage that a squirrel-cage motor can be employed to drive it, thus obviating the sparking difficulty. It can also be more easily adjusted than the disc machine to follow irregularities in the coal seam. The chain type is extensively used with very soft and friable coal, but does not appear to possess any advantages over the bar type for this class of cutting. After referring to the necessity for interlocking arrangements for the plug connections of the trailing cable, the author emphasises the importance of effectively earthing the motor casing. The motors for coal-cutters vary between 20 and 40 h.p., and are of the totally enclosed flame-proof type. In the case of a certain 26-in. seam of hard steam coal, the underground cost of production per ton was reduced from 5s. 1½d. to 4s. 6½d. by the use of a coal-cutter, including capital charges and repairs. Thus a saving of 7d. per ton was effected, besides the increase in value due to the greater percentage of round coal.

With regard to haulage, Mr. Miller mentions that with main rope haulage (used where a single road is to be worked with gravity return) it is essential that the motor should be capable of starting up slowly, to avoid excessive strains on the tub couplings. For large gears, the maximum speed would be from 8 to 12 miles per hour. Main and tail haulage, used for level roads, also necessitates slow starting up of the motor with considerable torque. Liquid starters are frequently used with these. Endless-rope haulage, adopted extensively on long double roads, is arranged to run at 1¼ to 2½ miles per hour, and provides practically a steady load all day, so that a squirrel-cage motor, driving through a friction clutch, may be used. As an example of the economy of electric haulage, the author mentions the case of a 500-yard road with an endless-rope haulage running at 1⅓ miles per hour, and absorbing 33 h.p. The total output of coal is 300 tons per day, and the cost of working 0·39d. per ton. When worked by steam gear situated at the surface, the working cost was 1·77d. per ton, so that a saving of £500 per annum has been effected.

Electric locomotives, continued the author, require at least 6 ft. headway, and can only be used in intake roads near the down-cast shaft on account of the sparking at the trolley wire, and are not used much in this country. With regard to electric winding, the author thinks it probable that the heavy capital charges of main electric winding gear will neutralise any saving in efficiency over steam winding, except where a cheap supply of power is already available. Small winding gears of from 40 to 100 h.p. are employed in a number of cases to raise coal from one seam to another in order that the main winder may be run from one level only at the maximum speed. In a mine of average size, the power used for ventilation would probably amount to several hundred horse-power, and would tend to ensure a good load factor. Finally, the author referred to the use of the Tirrill regulator and the Holmes-Alderson fire-damp safety cut-out, described in ELECTRICAL ENGINEERING, Vol. VI., Mining Supplement, p. cxxvi.

ELECTRICALLY-OPERATED COAL-HOISTS

At the meeting of the Institution of Mechanical Engineers on January 20th, a Paper by Mr. Walter Dixon and Mr. G. H. Baxter, entitled "Modern Electrical Dock Equipment, with special reference to electrically-operated Coal-hoists," was read. After running over some of the relative advantages of electrically- and hydraulically-worked dock appliances, a description was given of the electrical equipment of the Rothesay Dock of the Clyde Navigation Trustees, which includes the only electrically-driven coal-hoists in Great Britain, and in which the equivalent of the hydraulic accumulator has been provided in the shape of flywheel storage of power at the generating plant on a similar principle to the Ilgner winding system. The dock has its own steam-driven power station, and the electrical apparatus already at work consists of a pair of 32-ton coal-hoists, 18 four-ton cranes, 27 one-ton capstans, two tipping turntables, and two five-ton pierhead capstans. Further plant is in course of construction. A general description of the plant, including the flywheel generators, was given in ELECTRICAL ENGINEERING, Vol. I., May 2nd, 1907, page 749, further details of the cranes were given in Vol. II., page 730, and of the capstans in Vol. III., page 301.

The most interesting part of the Paper refers to the coal-hoists. These are of the high-level fixed type, arranged that the loaded wagons are run on the tipping platform at the quay-level, raised to the required height and tipped, after which the empty wagon is lowered to the high-level inclined viaduct, leaving the hoist at a height of about 17 ft. from the ground, and gravitating to the siding, the cradle then being lowered to the ground-level to receive the on-coming loaded wagon. One is designed for a lift of 60 ft. and the other for a lift of 50 ft., and each is capable of dealing with wagons containing 20 tons of coal. A mean hoisting speed of about 100 ft. per minute was adopted, corresponding to 30 seconds for the rise of 50 ft., and about 300 h.p. is required during this operation. About the same power is required for tipping the full wagons to an angle of 45° in six to nine seconds, so that the motors for the two motions are duplicates. The hoisting motor drives, by means of an elastic coupling and also an ordinary jaw-coupling, a pinion which engages with a spur-wheel upon the countershaft, this spur-wheel and pinion running in a cast-iron casing. At each end of the countershaft a pinion is fixed which engages with the spur-wheels firmly fixed to the hoisting-drums, the drums being so arranged that the ropes go directly to the cradle without the intervention of guide-pulleys. The whole of the gearing, with the exception of the motors, is erected upon a cast-iron bed-plate to obviate errors in erection, and both motors are mounted upon one base-plate, which is bolted to the gearing base-plate. For the purpose of taking up the slack of the tipping rope during the raising of the platform, a third drum, of barrel shape towards one end, is connected to one of the hoisting-drums. The tipping gearing generally is similar, excepting that only one drum is employed.

The brakes for both hoisting and tipping are of the friction clinch type, the brake-bands being kept tight during the hoisting, and the clinches revolving freely in the hoisting direction. By this means, the load is held in suspension immediately power is disconnected from the motor. In lowering, the brake-bands are released by electro-magnets in the usual way. Due to the fact that the hoisting and tipping motors are duplicates of each other, it has been possible to provide a simple arrangement by means of which one motor can work both motions in case of breakdown to either motor, thus enabling coaling to be proceeded with, and avoiding serious delay. The whole of the control is arranged from the attendant's cabin, situated near the top of the hoist. There is only one control-lever, which works in a quadrant or frame, and, by moving this lever in the various positions, the attendant has control of the hoisting, tipping and jib-crane, the only other controller being a small one for controlling the slueing of the jib-crane. Gearing is arranged in connection with this control-lever frame, which automatically renders it impossible for any of the motions to exceed their predetermined efforts, and it is also impossible for the attendant at starting to move the lever at such a rate as to accelerate at too great a speed, and consequently throw an undue load upon the generating station.

The official tests have shown an overall combined efficiency of 72 per cent., and further tests, after two years' actual work, have given a figure of 80 per cent. During twelve months the two hoists have dealt with 556,419 tons of coal in 70,604 wagons, with a consumption of 80,164 units. On the average, 6·94 tons of coal were handled per unit, but as much as 23 tons per unit was sometimes reached. Thirty wagons would be shipped in 31 min. 32 sec., which, with the largest wagons that the hoists will take, is equivalent to 1,140 tons per hour. The costing of working at 1d. per unit works out at 10s. 11d. per 1,000 tons. This compares with results of tests of hydraulic hoists with water at 9d. per 1,000 gallons, giving 18s. 11d. The result of two yeors' working shows that the cost of upkeep has not exceeded that required for the upkeep of coal-hoist plant operated by hydraulics or steam.

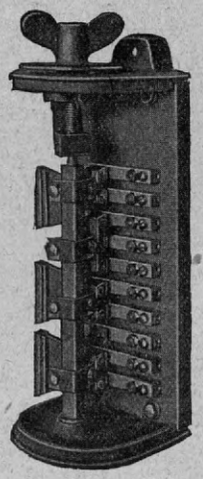
At the conclusion of the Paper, the authors submit that they have, by this entirely electrically-equipped dock, shown that, apart from the admitted advantages of electric power, the relative position of electric and hydraulic power is now as follows :—Electric and hydraulic systems are equally reliable; the cost of working with electric and hydraulic power is equal at full load, but under variable and low load conditions, electric power is cheaper; electric power has now the equivalent of the hydraulic accumulator; electric power can be applied to all dock appliances, and has greater flexibility than hydraulic power.

The discussion was opened by Mr. J. A. F. ASPINALL, who said that two gallons of water at a pressure of 1,000 lbs. per sq. in. was equivalent to 1·333 h.p., which, if used for one hour, was practically one Board of Trade unit. In the north of England water was supplied at this pressure at 1s. 6d. per 1,000 gallons, and on this basis the cost of the equivalent of a Board of Trade unit will be 2·16d., against electrical energy at 1d. per unit.

Colonel F. W. TANNETT WALKER complained that in this particular case, makers of hydraulic machinery had not been given a fair opportunity to show what they could do. He regarded the performance of the electric coal hoist of tipping 30 waggons in 30 minutes as nothing out of the ordinary, and suggested this was the longest time the hoist could keep up this rate of work, but the whole question was a traffic question, and being able to deal with any load according to the shipping which required to be dealt with. He thought that the method of braking employed was disadvantageous in that it necessitated a stop before the coal was actually tipped. A much smoother action was obtainable by hydraulic machinery, with a consequent saving in time. One of the hoists at Rothesay had shipped 278,000 tons of coal per annum, but he pointed out that the Taff Vale, Great Western, and North British companies were regularly doing 400,000 tons, and also mentioned instances in which many thousand tons of coal were tipped in a few hours. The price of 9d. per 1,000 gallons taken by the author for hydraulic power was quite beyond the actual figures that were being paid.

Mr. W. H. PATCHELL supported the previous speaker in favour of hydraulic coal hoists, and mentioned an instance in which he had installed one in an electric power station because it was cheaper.

Mr. E. B. ELLINGTON considered the authors were making a bold assertion in stating that electric and hydraulic coal hoists were equally reliable, but admitted that they had only two or three years' experience to go upon, against the 60 years' experience with hydraulic machinery. He agreed that at full load electric and hydraulic machinery were equally economical, but he was not yet convinced that this condition of equality was maintained at the lower loads or on a variable load. It seemed to him that in order to get their comparative figures of cost of power, the authors had about halved those for electricity, and doubled them for hydraulic power.



Mr. C. O. RIDLEY (Messrs. Armstrong, Whitworth & Co.) also made a few remarks in which he advocated the use of hydraulic machinery as opposed to electrical machinery for this purpose.

The discussion was then adjourned until February 17th.

The Pretoria Pit Explosion.—At the resumed inquest at Westhoughton, various startling allegations have been made by friends of the deceased miners and others who have worked in the Pretoria Pit with regard to the gaseous and heated state of the atmosphere, and the relighting of lamps in a return airway where there was sufficient gas to put them out. Sparking at the switch of the conveyor which was situated in a part of the mine which suffered from the explosion was again referred to, but no technical evidence was given. The general manager, Mr. A. Tonge, described the ventilation of the mine in some detail, and stated that he was not aware of the presence of a dangerous amount of gas. He was surprised to learn that a boy of 16 had been found to have a relighting key for the Wolf lamps in his pocket. He thought the explosion originated in the North Plodder mine in an area not including the coal face where the conveyor referred to and a coal-cutter were used, but including another district where there was a second coal-cutter. The explosion must have been caused by the ignition of gas or coal-dust which, if present, could be ignited even by sparking from the brake of a jig pulley. The electrical apparatus, he said, was on the best possible system, and the miners' agent had recently inspected it and complimented him upon its condition.

ELECTRIC POWER AT A TIN MINE

THE properties of Pusing Bharu Tin Mines, Ltd., and the Siputeh Tin Mines, Ltd., are situated in the Malay Peninsula, district of Kinta, the nearest towns being Ipoh and Batu Gajah. The former company was registered in 1907 to acquire and work about 170 acres in this district, which is rich in low-grade tin, the value of the mineral won from the Pusing Bharu property in 1909, the first complete year of working, being £41,147. The latter company owns about 200 acres in the same district. The mines are worked electrically from a plant established conjointly by the companies. The order for the electrical machinery for this was placed with the British Westinghouse Electric & Manufacturing Co., Ltd., in 1907, through the Wilfley Mining Machinery Co., Ltd. Erection work was begun in January, 1908, and completed in the June following, when the mines started running.

The power-house, about half-way between the two mines, is equipped with three Babcock & Wilcox water-tube boilers, with mechanical stokers, three Bellis & Morcom non-condensing engines, direct coupled to British Westinghouse three-phase, 50-period, 150-kw., 220-volt alternators, with direct-coupled exciters. The sets run at 428 r.p.m. The control gear consists of a five-panel switchboard of black enamelled slate, embodying three generator panels with field rheostats, automatic oil switches, and the necessary instruments, one feeder-panel, fitted with two automtaic oil switches (one for each mine), and one panel fitted with a similar switch for a 60-kw., three-phase, 2,200/440-volt, oil-cooled transformer, which supplies current to the motors driving the power-house pumps, &c.

The transmission lines, which are each about one mile long, are of No. 4 hard-drawn copper wire on triple petticoat insulators, with a galvanised-iron earth wire stretched above for lightning protection. On each end of the line there is a horn-type lightning arrester. The mains feed into the the Pusing Bharu sub-station, which is equipped with six British Westinghouse, single-phase, 2,200/440-volt, oil-cooled transformers, connected in mesh and forming two groups of 150-kw. capacity each. There is one two-panel black enamelled-slate switchboard, consisting of one incoming high-tension panel fitted with one non-automatic oil switch and the necessary instruments, and one ordinary low-tension feeder-panel. From the sub-station there are two low-tension transmission lines of No. 5 hard-drawn copper wire, supplying a three-phase, 50-period, 15-h.p., 440-volt, slip-ring induction motor, fitted with a face-plate starter and a reversing switch, the latter having been made locally. This motor was supplied as a constant-running machine, but has been found to run equally well as a reversible motor for winch-driving. In the present case, it drives a double overburden winch for clearing away waste earth by means of endless haulage.

There are also two transmission lines feeding a 20-h.p., three-phase, 50-period, 440-volt, 945-r.p.m., squirrel-cage induction motor, direct-coupled to a Worthington 6 in. turbine pump which has an output of 660 gallons per minute with a 60 ft. head, a motor of the same type and output, but of a higher speed (1,400 r.p.m.), driving a Worthington 5 in. double-stage pump with an output of 375 gallons per minute against an 80 ft. head, and an overburden winch similar to the one already mentioned, but driven by an 8-h.p., three-phase, 50-period, 440-volt, slip-ring induction motor, with face-plate starter and locally-made reversing switch.

The tin-bearing earth is cut by coolies and loaded into trucks, and is then pulled up by an incline double-drum winch and endless haulage, driven by a 40-h.p. motor. This winch is fitted with a no-voltage brake solenoid direct into the puddler shed, and equipped with a reversing controller. The ore is then dumped into a chute, and monitored into the high-speed puddler, the water for monitoring being supplied by a Worthington 10 in. single-stage pump of 1,333 gallons per minute output, against a 30 ft. head, driven by a 25-h.p., three-phase, 50-period, 710-r.p.m., 440-volt, squirrel-cage induction motor, direct-coupled to it. The high-speed puddler consists of a shaft fitted with knives of forged steel, which chop up the large hard lumps of clay. This is belt-driven by a 25-h.p., squirrel-cage induction motor. The clay then has a natural feed into the low-speed puddlers, driven by a similar motor, which chops it up still finer. The overflow from the low-speed puddlers runs into the rifle races, which catch the tin as it escapes from the puddler and allow the tailing or useless material to flow away into the settling pond. There are 17 motors in use at Pusing Bharu, developing a total horse-power of 160. The Siputeh mine is of a similar character, but has only one incline to the puddling shed, and develops only 60 h.p. Both the mines have centrifugal pumps, driven by 15-h.p., squirrel-cage induction motors for auxiliary pumping.

An interesting fact about this installation is that the entire electrical plant was erected by unskilled native labour under the supervision of one electrical engineer. It has now been run for two years to the entire satisfaction of the company, in spite of very adverse conditions, the motors being at all times exposed to wet and dirt in the puddling sheds, and, in fact, in all parts of the mine where the tin-bearing earth is handled.

MINING SWITCHGEAR

A PAPER entitled "Recent Progress in Mining Switchgear," by Mr. G. Stevenson, was read on December 21st at a meeting of the Mining Institute of Scotland at Glasgow. After explaining the cause of arcing at switches and the effect of the self-induction of the circuit, the author described some typical forms of underground switchgear by the aid of lantern slides. The first requisite of such switchgear was the avoidance of all perishable or fragile materials. Oil switches had entirely superseded air break switches for the purpose. A special feature of underground switchgear should be the provision for solid bonding of the armouring of the cables by means of cable boxes bolted direct to the framework of the switch. The switches should also be well protected as regards accidental contact with live parts. Such contact was prevented in the type shown by a lock on the cover arranged so that the oil vessel cannot be removed until the lock is opened. The isolating links in another pattern shown were contained in a chamber, the door of which was interlocked with the switch. Various forms of automatic release were mentioned, such as those which trip when the voltage falls to 50 per cent. of its normal value, and prevent the switch being closed unless the voltage is over 50 per cent. of the normal. The author was not in favour of the present tendency to adopt a multiplicity of automatic features in mining switchgear. Two-coil trips were usually sufficient on three-phase systems, except where the neutral point was earthed. The great success of the oil switch he attributed mainly to its ability to open the circuit with great certainty and safety, and the fact that practically no rise of voltage occurs when the circuit is broken under oil. The effective action of the switch in breaking the circuit under oil is apparently due to the cooling action which the oil has on the resulting arc, which is extinguished promptly by the temperature being lowered below the value at which the arc can hold. Oscillograph records show that when an air-break switch is opened, the circuit is actually broken whenever the current falls to zero, but that the copper vapour does not have time to escape; consequently, as the potential rises again on the next cycle, the arc is re-formed. This process of rupturing and re-forming goes on until the blade has been drawn such a distance from the clip that the arc cannot re-form, and is apt to cause very serious strains on the insulation. This effect is not met with in oil-break switches, as, once the arc breaks, it is unable to re-form, owing to the oil washing in and cooling off the copper vapour and the surface of the contacts. Oscillograph records actually do show that the arc is broken when the current wave is passing through zero point.

Various types of controller were described, including the contactor system for large motors. This had been developed for alternating as well as continuous currents, and the magnetic blow-out arrangements were equally satisfactory in both cases.

With regard to surface switchgear, the author favoured enclosing each item of the equipment in a separate and self-contained fireproof cell of moulded stone, closed by iron doors interlocked with the isolating switches.

Colliery Supply.—The Staveley Coal & Iron Co., Ltd., have under construction at Devonshire a power station to supply electric power to their various collieries. The Hartington, Ireland, Seymour, and Markham pits will be connected first, and mains will subsequently be carried to the Barlborough, Warsop Main, Bonds Main, and Calow Main collieries. It is stated that the scheme will result in an economy of working to the extent of some £8,000 per annum.

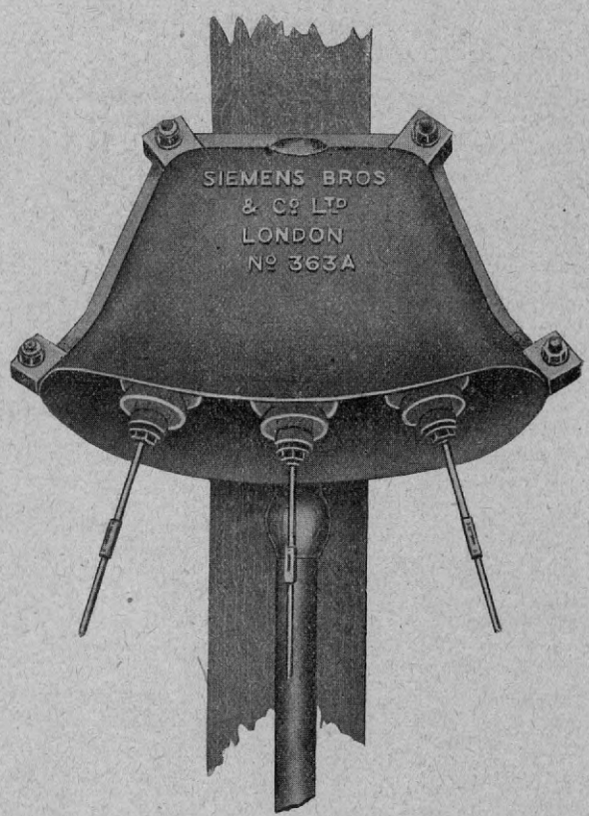
ELECTRICAL EQUIPMENT OF A NEW ZEALAND COAL MINE

THE following particulars of the electrical equipment of the Westport Stockton Coal Co.'s mine, which is important in view of the extent of the deposits and the high calorific value of the coal, are taken from a Paper read by C. J. Holroyde before the Engineering Association of New South Wales and abstracted in the *Australian Mining Standard*. The coal deposits lie at a height of from 2,500 ft. to 3,000 ft. above sea-level, and the coal has to be brought down. There are two main inclines, one above the other, with steel rope haulage, by which the trucks are handled, the loaded cars going down pulling the empties up, the rope speed being controlled by a hydraulic brake on each incline. From the head of the top incline to the mine, electric locomotives handle the trucks both ways, gathering loaded tubs from the various working faces in the mine proper, and distributing the empty tubs.

A tunnel leads from the coal-bins to the foot of the first incline, and at the head of the second incline the trucks run on to the level, where the main electric locomotives begin their run. These locomotives are supplied at 250 volts D.C. from an overhead trolley wire, and draw the loaded tubs from the mine to the head of the incline, and pull back the empty tubs. They weigh 20 tons each, and are equipped with master controllers to enable them to be worked as separate units, or coupled, as desired. Their draw-bar pull is 7,500 lb., at a speed of 8·2 miles per hour. To prevent them getting away on the steeper grades, a third (dead) rail is located in the middle of the track, projecting a few inches above the level of the two outside rails, and a powerful toggle brake on the locomotive engages both sides of the head of this centre rail. The smaller "gathering" locomotives weigh about 6½ tons each, and have a draw-bar pull of 2,500 lb., at a speed of 7·4 miles per hour. These locomotives are for pulling the full tubs to be made up into trains for the main locomotives to handle, and for breaking up the trains and distributing the empty tubs to the working faces. The coal tubs weigh 1,500 lb. each empty, and when loaded 4,500 lb.; in other words, each loaded tub carries 30 cwt. of coal. The "gathering" locomotives are equipped with a reel, automatically worked from the axle, containing 900 ft. of flexible twin cable, to enable the locomotive to have an operating range of this distance beyond the farthest point of overhead construction.

The track from the head of the top incline right into the mine is of 56 lb. rails. These are 40 ft. long, and at each joint are bonded with two No. 00 bonds, being cross-bonded every three rails. The gauge is 36 in. The track is single at present, and is provided with the necessary turn-outs to handle the traffic. The overhead construction comprises a G.E.Co. (U.S.A.) grooved No. 0000 (0·46 in. diam.) trolley wire in parallel with a bare stranded cable. The feeder cable is connected to the trolley wire on an average every 150 ft. The trolley wire is 7 ft. 8 in. above the level of the rail head.

The power house is some distance from the mine itself, and has generating plant installed aggregating 1,000 kw. This includes two A.-C. sets and one D.-C. set. Three sub-stations feed the overhead trolley network at the mine, and are served with three-phase current at 6,600 volts over a six-mile transmission line. Telephone lines connect the three sub-stations, power house, offices, &c., and each locomotive carries a portable telephone.



The mine is exceptionally fortunate in regard to ventilation, in that but small fan capacity is required. Two fans, each driven by a 30-h.p. B.T.H. three-phase 500-volt motor, are used in the tunnels. These motors are belted to centrifugal fans. The object in using 500-volt three-phase motors for driving the fans is that this service will be continuous, irrespective of any possible interruptions to the trolley overhead network. In addition to the above, there are six Sturtevant blowers, each belted to a 5-h.p. D.-C. 250-volt motor, which will be located as required at different parts of the workings; the motors taking the current from the overhead trolley. The natural drainage is so excellent that the only provision made is a small Worthington pump, direct geared to a 5-h.p. 250-volt D.-C. motor. This set is portable, and readily moved to any point of the mine where it is necessary to pump out any dips that occur in working.

Coal-cutting machines are employed in the mine, the company having started with two Sullivan board and pillar chain machines, with 6-ft. cutting bar, driven by a 30-h.p. motor. The company has already proved 30,000,000 tons of coal in sight, the coal averaging about 14,000 B.T.U. The seams vary from 6 ft. to 12 ft. in depth in the working already opened, and the coal is entirely free from slate and bands. The mine is fortunate in having a solid sandstone roof, which will necessitate the use of very little timber for its support.

The main storage bin at the base of the incline has a capacity of 5,000 tons. The loaded tubs run into the bin by gravity and automatically discharge the coal on to travelling elevators, which deliver it into the various compartments (screened and unscreened coal) of the bin. There are three elevators, operated respectively by two 10-h.p. and one 15-h.p. motors. The shakers are operated by three 5-h.p. motors. An electric hoist operated by by a 52 B.H.P. A.-C. motor, is used to haul the empty Government railway trucks out of a dip on to an incline, from which they are distributed by gravity into the various tracks under the bin. After the trucks are loaded they are sent to Westport (22 miles distant), on the west coast of New Zealand. Another electric hoist, worked by a 112 B.H.P. A.-C. motor, is used for hauling the mine tubs through the tunnel at the base of the incline.

A DIVIDING BOX FOR OVERHEAD LINES

Messrs. Siemens Brothers & Co., Ltd. (Caxton House, Westminster, S.W.), have introduced a special type of cast-iron dividing box, for use in exposed positions, such as on overhead transmission poles, &c. The illustration shows one of these boxes attached to a wooden post. The incoming cable enters through a brass wiping gland, and is connected to special angle fittings, from which bare copper rods are led out obliquely

DIVIDING BOX FOR CHANGE FROM CABLE TO OVERHEAD LINE.

through substantial insulators at the bottom of the box. The insulators are protected by a weather shed formation of the lower portion of the casting, which prevents the collection of snow or other conducting substances between the live terminals. The two halves of the casting are provided with a machined facing, to ensure watertightness, and after the connections are completed, the whole box is filled with hard insulating compound. These boxes are supplied both for high-tension and low-tension work.

Society of Engineers' "Status" Prize.—This prize may be awarded by the Council of the Society of Engineers (Incorporated) each year for the next three years (if papers of sufficient merit are received) for the best paper written by any person on the subject of "How to Improve the Status of Engineers and Engineering, with special reference to Consulting Engineers." Essays not exceeding 6,000 words must be sent to the Secretary, 17 Victoria Street, London, S.W., not later than May 31st.

ELECTRICAL MINING PATENTS OF JANUARY

AMONG the patent specifications published during the past month, and of interest to electrical mining engineers, were three describing improved forms of coal conveyors. The first is No. 30,123 of 1909 by W. H. Barker, of Stoke-on-Trent, and relates to conveyors of the reciprocating type. It covers a method of mounting the trays in combination with Aitken gear in order to obtain a much quicker forward movement than the backward movement. No. 30,127 of 1909, by W. Wilson, of Armadale, describes a coal-face conveyor consisting of a long belt to which trays are attached. The belt is drawn along the coal-face to the end where the hatches are, where it passes over a hexagonal roller, causing the trays to discharge. The direction of motion of the belt is reversed when all the trays are empty. No. 30,361 of 1909, by J. Watson, of Motherwell, describes a conveyor comprising a number of trays which are drawn along the coal-face by means of an electric haulage gear. Stops are provided on the haulage rope to effect the reversal of the motor automatically when the trays reach the ends of the face. Means are also provided for reciprocating the trays and for shooting the coal into the hatches automatically.

A specification by E. E. Rogers, of Wimbledon, No. 4,066 of 1910, describes an electrically interlocked plug and socket connector for lamp and motor circuits, which cannot be disconnected while the circuit is alive. The socket is provided with a solenoid connected in series or parallel on the supply side, the plunger of which engages with a suitable projection on the plug so long as the solenoid is energised. In the case of the parallel connection, the plug can neither be inserted nor withdrawn if the circuit is alive.

Specification No. 4,357 of 1910, by F. A. Scott and D. Miller, of Glasgow, relates to coal-cutters of the disc pattern, in which the haulage drum is placed at one end of the machine, and describes an improved gear which reduces the height of the machine by avoiding the necessity of providing clearance below the machine for the passage of the haulage rope for forward travel. A vertically arranged drum is provided, and, for forward travel, the rope passes at the side of the machine.

A double bayonet joint for miners' lamps is described in Specification No. 4,451 of 1910, by P. Rennert, of Westphalia. Spring-locking pins on the oil-tank, withdrawable only by a magnet, snap into slots connecting two superposed bayonet slots of the oil tank, and lock the outlet for the bayonet projections of the upper lamp portion.

Specification No. 19,659 of 1910, by W. Aitken and British Insulated & Helsby Cables, Ltd., covers the various details of construction in a portable magneto shot-firing instrument.

Cumberland Branch of the Association of Mining Electrical Engineers.—A meeting of this branch was held on January 21st, when it was announced that the President, Mr. H. Maurice, would be present at the next meeting, on February 18th. A short discussion was held on the question of examinations, and it was mentioned that the first would be held on March 14th and 21st. The papers would be sent out by Prof. W. M. Thornton, and the actual examinations conducted by the President and Secretary of each branch. The paper by Mr. R. R. Smith, on "Inspection and Repair of Underground Plant" (see ELECTRICAL ENGINEERING IN MINES, January 5th, page vii.), was then discussed. Mr. Blair did not think that Mr. Smith's system of inspection would be practicable in any but very large mines. He thought that in future the mechanical and electrical engineering staffs would be amalgamated. The chief engineer should be both mechanical and electrical. Mr. J. Glynn Williams took up some points of detail in the paper, and in particular objected to the use of cast-iron slip rings on induction motors, as they were liable to become rusty when the motor is standing, and to cause sparking when starting up again.

Articles of Interest to Mining Electrical Engineers published in "Electrical Engineering" during January.

Jan. 5th.—Monthly supplement on ELECTRICAL ENGINEERING IN MINES, opening with an abstract of a Paper on "Electricity in New South Wales Collieries," by Mr. E. K. Scott. Reports are given of discussions on electric winders before the Newcastle and Manchester Sections of the Institution of Electrical Engineers, at the latter of which a Paper by Dr. E. Rosenberg was read. A note is given on the possible cause of the explosion at Bolton, and discussions before two branches of the Association of Mining Electrical Engineers on a Paper by Mr. R. R. Smith on the care of underground plant are reported. Some notes are also given on mining patents published during December.

Jan. 12th.—Notes on the rotary converter. Illustrated descriptions of some new switches, &c. A Paper and discussion on the Merz-Price system of protection.

Jan. 19th.—Illustrations of a mixed-pressure turbo-alternator set. Special literary supplement, with reviews and list of recommended books on all branches of electrical engineering. Description of a telephone equipment for use on high-tension circuits.

Jan. 26th.—Illustrated description of a metal filament lamp factory. Further discussion on the Merz-Price system.

HIGH TENSION TRANSMISSION LINES

TWO papers on this subject were discussed at last Thursday's meeting of the Institution of Electrical Engineers. One, by Mr. W. T. Taylor, was on "Modern Long-distance Transmission of Electrical Energy"; and the other, by Messrs. R. Borlase Matthews and C. T. Wilkinson, was entitled "Extra High-pressure Transmission Lines."

The first paper was read in abstract by Mr. J. F. C. Snell, in the absence of the author. After some general remarks, a *résumé* was given of some of the formulæ used in the calculation of the size of wire required, the self-induction, capacity, and the resistance and reactive drops due respectively to the power component of the current, the wattless component, and the charging current. The latter has, of course, a negative value, and sometimes causes the voltage at the far end to be higher than that at the station. The author was in favour of subdivision of the conductors forming each phase in large systems, with connecting switches at suitable points, as increasing the electrostatic capacity of the entire line, decreasing the inductive reactance and increasing the reliability and flexibility of the system.

Dealing then more particularly with generating stations, the author gave some diagrams of typical arrangements, and said that of late practice had been tending to outdoor installations of lightning arresters, entering buildings from the roof, and arranging high-voltage oil switches in steel tanks, operating them by primary relays and using the switch bushing as the primary for series transformers. With regard to the line itself, he followed out further the advantages of double circuits and simplicity in the arrangement of the sections and branches. Typical diagrams from actual systems were given. With the increase in price of wood and the decreasing price of steelwork, practice was, he said, steadily leaning towards steel towers and poles as substitutes for wooden poles. Spans from 300 to 750 feet are used, and towers 40 to 55 feet high. The overhead earthed steel cable now usual for lightning protection added greatly to the stability of the towers. Particulars were given of mechanical tests of steel towers, and illustrations of typical designs were shown. From the depreciation point of view, the life of steel towers should be not less than thirty-five years. That of wooden poles, however, averaged twelve years.

On the design of insulators it was remarked that size alone did not produce efficiency, but rather the surfaces in relation to the mass; 60,000 volts was about the limit for pin-type insulators, because a further lengthening of the pin increased the leverage and weakened the support, while the weight increased. For pressures from 60,000 to 100,000 volts the suspension insulator of four to eight parts in series was standard. It required, however, a higher tower, but allowed great flexibility to the line. The conductor should be anchored about every mile and at all corners. The maintenance of suspension insulators was said to have proved only ten per cent. of that for the pin type. Illustrations of designs in use were shown, and results of tests were mentioned. In these designs care is taken to get the maximum average length efficiency, that is, the ratio of the voltage at which the insulator flashes over to the breakdown voltage of an air-gap equivalent in length to the insulator.

The following general recommendations were given regarding line protection:—In large generating stations arresters should be installed on the generator busbars, or low-tension side of the power transformers to protect them against internal surges. On all outgoing and incoming transmission lines arresters should be placed on each line. They should be installed through a disconnecting switch preferably outside of the station, or as near as possible to the point of entry into the station. Arresters or lightning rods should be installed at high places where the lines are exposed to lightning, such as the top of a mountain where no ground wire is used. At least one ground wire should be installed along the top of the transmission line and grounded at every pole or tower. The aluminium type of arrester was favourably spoken of. The author did not express any very definite view on the relative merits of star and delta connections, but said that in the majority of cases delta connections were used but required larger apparatus and insulators. In conclusion, the author touched on the question of rates, and said that the present electric power rates on practically all hydro-electric systems of any importance and magnitude are based on a fixed charge per horse-power per month plus a definite amount per kilowatt-hour as recorded on the meter.

The second paper was read by Mr. Borlase Matthews. The author looked forward to the time when 200,000 volts would be considered practicable, and said that the lengths of lines were limited by financial and not by engineering considerations. Passing on to matters of detail, they dealt first with supporting systems, and pointed out the advantages of a line of flexible steel towers with a rigid anchor tower or a double-guyed tower at intervals. The strain was thus better distributed when a line broke. Curves were given of the comparative cost of flexible towers, rigid towers, and wooden poles. It is not practicable to build wooden pole lines for above 40,000 volts for two circuits, as the length of cross-arm becomes excessive; and, indeed, at about 50,000 volts the cost curve would cross that for flexible towers. The use of clamps designed to release the wire when a certain pull is reached was considered, and successful results in this direction were recorded.

With regard to insulators, the disc or suspension type were stated to be both easier to construct and less fragile than the pin type. Illustrations were given of the types most frequently used, which are designed for a working pressure of from 18,000 to 30,000 volts per disc, and have a net flash over voltage about $2\frac{1}{4}$ times this value. It is interesting to note that when testing a string of suspension insulators dry, the voltage will divide in accordance with capacity effects, and when tested wet, in accordance with resistance effect. The losses from corona effects were only dealt with briefly, but some interesting illustrations were shown, and the great protection of the insulators from lightning effect by an earthed metal ring surrounding them, and of the line by an overhead earthed wire was mentioned. Damage caused to lines by wind and by the weight of ice collected on the wires was referred to, and it was mentioned that in the United States, where the weather conditions are more severe than here, it was usual to allow in designing for $\frac{1}{2}$in. thickness of ice all round the wire with a 65-mile per hour actual wind velocity occurring at the same time, or $\frac{1}{4}$in. ice with an actual wind velocity of 77 miles per hour.

The following are among the general recommendations made regarding line construction:—

Districts subject to lightning should be avoided, and valleys chosen in preference to routes over hills. Duplicate lines should be kept as much as a mile apart if possible. Two ground wires are preferable to one; they should be earthed to every steel tower or at every third wooden pole. Lightning rods with sharp points projecting at least 6 feet should be provided at every tower. Insulators must be tested under dry and rainfall conditions, and the flash over voltage should be considerably greater than twice the line voltage. The line should work at a voltage slightly below the critical corona voltage. All towers must be efficiently earthed. Line wires should be 1 foot apart for every 10,000 volts.

Specifications for steel transmission line towers and suspension insulators are appended, and also a list of 28 typical transmission systems of over 50,000 volts.

DISCUSSION.

Mr. D. C. JACKSON (President, American Institute of Electrical Engineers), after pointing out that the interest of Americans in this subject was due to the larger amount of water-power in the United States, and also to the fact that many of their coal mines were far removed from large centres of utilisation, said there was undoubtedly a tendency to develop schemes for supplying large areas from few centres, with very large power houses, and although power stations with a hundred thousand kilowatts were not yet the rule, yet he thought eventually there would be many, especially in connection with railways. The extension of the limit of voltage for generation and transmission would play an important part in this movement, and if a limit of, say, 300,000, or even 500,000 volts could be reached, this would make it possible to couple almost any power station in the United States with any other. At present, however, there were difficulties if they went above 120,000 volts. The losses between wires due to corona, &c., were really marvellous, especially in the higher altitudes, and something more had to be learned before they would be able to go much further. He had ample confidence, however, in the ability of the engineers of the world to make the necessary discoveries and inventions.

Mr. B. WELBOURN (British Insulated & Helsby Cables, Ltd.) said both authors seemed to suggest that power transmission could only be by overhead lines, and that underground transmission was out of the question. But there were cable-makers on this side of the Atlantic who were prepared to manufacture cables of 30,000 volts A.C. three-phase, or up to 100,000 volts continuous current. There was a considerable amount of pole line work being carried out in Newcastle, Durham, Yorkshire,

Hosted by Google

and Scotland, almost all by means of creosoted wood poles. The authors' estimate of 12 years for the life of wooden poles must surely refer to untreated wood. With creosoted poles he thought the life would be nearer 25 years. The longest span in this country was one which he hoped to put up in a few months, viz., 368 ft., this being necessary in order to get over wayleaves, but 80 yards was a common length. Neither of the Papers dealt with the automatic protection of the line nor aluminium wires. There was a good deal of the latter being used in this country, including a line at Aldershot, which was being put up by the War Office. The sizes used varied from No. 12 gauge to 1·4 sq. inches. The early troubles described by Sir John Gavey with aluminium had now been quite got over. A controversial point raised in both Papers was the use of a longitudinal earth wire. During a trip from the Atlantic to the Pacific, he had spoken to many engineers on the subject. There seemed to be great diversity of opinion on the point, and some of the most recent lines put up did not have any continuous earth wire. Some engineers condemned them root and branch. He agreed with the earth wire for mechanical reasons, and also for earthing purposes for the prevention of shock, but unless they were of the same material as the live wire, and therefore had the same life, it was very questionable indeed whether they ought to put up, because this might come down without it being known.

The discussion was adjourned until February 9th.

TRANSFORMER SUB-STATIONS

MR. P. V. HUNTER read a Paper on January 16th before the Newcastle Local Section of the Institution of Electrical Engineers on the design of sub-stations on power supply systems. He confined his remarks chiefly to the arrangement of buildings and plant, and dealt more particularly with the conditions met with on the north-east coast. It was most important, he said, to consider the sub-stations in relation to the whole supply system, and to design the switchgear not solely to suit the sub-station plant, but to meet the conditions imposed by the magnitude of the system and future developments.

With regard to cost, he remarked that the minimum cost per k.v.a. of naturally-cooled transformers is reached when

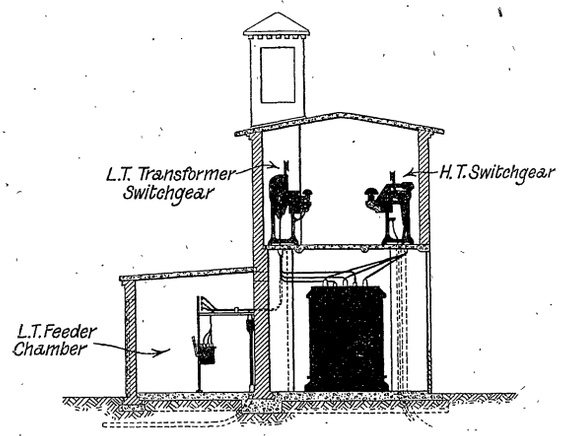

FIG. 1.—SUB-STATION WITH SEPARATE CHAMBER FOR L. T. FEEDER BOARD.

the size approaches 1,000 k.v.a., but up to this size, there is a reduction in cost per k.v.a. the larger the transformer. The cost of H.T. switch panels, on the other hand, was practically proportionate to the voltage, and more or less independent of the full-load current within working limits. A number of drawings of typical arrangements of sub-stations were given. The simplest arrangement, with all the apparatus in one chamber—transformers in the middle and L.T. and H.T. switchgear on either side, is suited only to very small stations, and is objectionable from the fire risk point of view, as well as large ground space occupied. A design, two-storied, such as in Fig. 1, with the transformers in separate cubicles, with special ventilating series, is preferable, although in some cases, where not more than two transformers will be required, a one-storey arrangement, with a pair of transformer chambers opening to the air at the ends and walled off from the switchgear, may be employed. The figure shows the low-tension feeder switchgear in a separate chamber, which, especially in cases of sub-stations on consumers' premises, is often found convenient. The dimensions of such a building depend on the maximum size of transformer to be accommodated, but, as a rule, there is no economy in employing units larger than 1,000 k.v.a. Extensions are easy with this type of sub-station. Further chambers can be added, side by side to any extent permitted by the site.

With voltages over 10,000 volts, where serious voltage surges are possible, special protective apparatus has to be provided for. In case of overhead lines, horn arresters may be placed in an additional chamber above that containing the H.T. switchgear. It is also sometimes advisable to provide surge arresters to each feeder panel; these, if of the roller

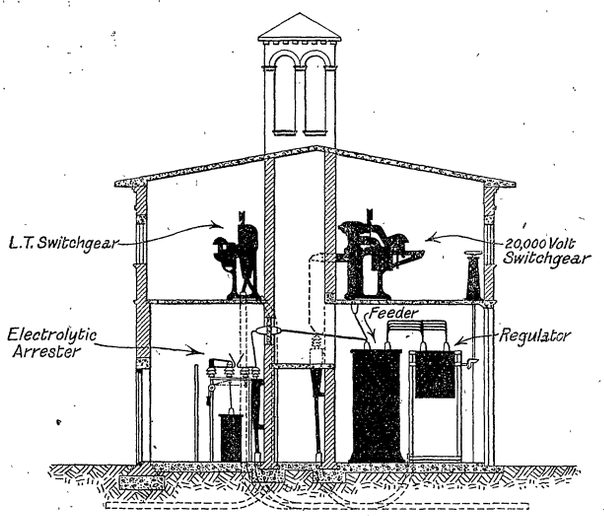

FIG. 2.—SUB-STATION WITH ELECTROLYTIC ARRESTERS AND FEEDER REGULATORS.

type, can be accommodated in small chambers alongside those containing the transformers. An arrangement where electrolytic arresters are provided for is shown in Fig. 2. In this design, space is also available for a feeder regulator. Where artificially-cooled transformers are required, special ventilation ducts are not required, and the oil- or water-cooling apparatus may be placed in a lean-to shed parallel to the row of transformer cubicles. In sub-stations for very large transformers, provision is sometimes necessary for lifting the transformers, as in Fig. 3, which represents the arrangement adopted at the junction points of the trunk mains on a 20,000-volt system where the energy is transformed to 6,000 volts for general distribution. They have, therefore, extremely important duties, and it is impossible to estimate the ultimate maximum load. In these circumstances, the sub-stations are designed with each section

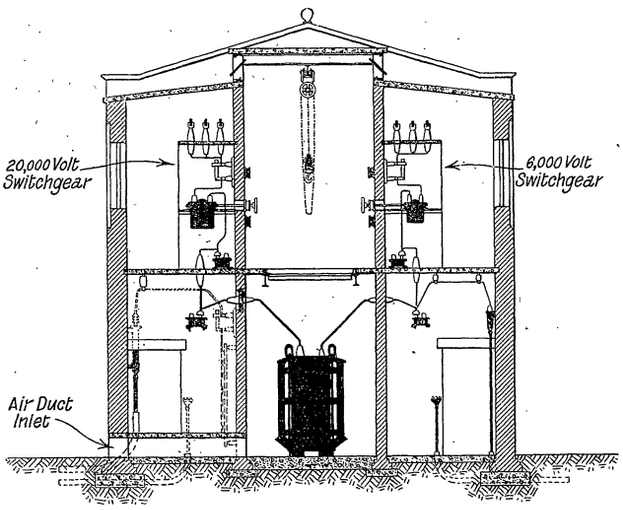

FIG. 3.—SPECIAL 20,000/6,000 VOLT SUB-STATION.

suitable for naturally-cooled transformers up to sizes of 1,000 k.v.a., but may be arranged to accommodate artificially-cooled units up to 3,000 k.v.a. each.

It is arguable, continued the author, that the same reasons which make lifting apparatus necessary for the artificially-cooled transformers also apply to the naturally-cooled apparatus. The question is somewhat involved, and is governed by the use likely to be made of the lifting apparatus. This is almost entirely a matter of individual experience, depending on the amount of trouble met with.

Hosted by Google

In any case, repairs requiring more than one or two days should be carried out at a central repair shop, where proper apparatus is available for repairing, drying out, and testing the transformers. On the other hand, it is objectionable to have to transport a transformer some distance to the repair shop for the sake of inspection and adjustment only, although, of course, this is to be preferred to lifting it out of the case in the open air.

ANSWERS TO CORRESPONDENTS

Correspondents must in all cases send their names and addresses with their queries, and, if they do not desire the reply to be published after their own name, should add a "nom de plume." Questions should be addressed to the Editor, ELECTRICAL ENGINEERING, *203-6 Temple Chambers, Temple Avenue, London, E.C. The Editor will not guarantee to answer all questions in this column, and the enclosure of a stamped and addressed envelope is therefore desirable. Books recommended will be forwarded on receipt of a remittance for the amount mentioned.*

J. A. HOPKINS.—Two-and-a-half brake horse-power.

L.—The first address you require is Finsbury Pavement House, E.C. The electric supply of Sydney is in the hands of the municipality, and the tramways are owned by the Government. The greater part of the new tramway contracts are now carried out by Australian firms who have no office in London.

E. H.—(1) The fee on application for a patent accompanied by provisional specification is £1; and on subsequently filing complete specification, £3. If the complete specification is filed within six months from the date of application and is accepted, a further "sealing fee" of £1 has to be paid. Renewal fees commence at the end of the fourth year, being £5 for the fifth year, £6 for the sixth, &c. (2) You can apply by post, by filling in a form obtainable from the Patent Office. (3) There is no need to employ a patent agent, but it is a course which we recommend, at any rate, when filing the complete specification, and, if you are not an adept at drafting patent specifications, we should recommend the employment of an agent from the start. If you are making application yourself, you had better obtain a copy of "The Patents Rules," price 7d. post free, and, in any case, you would also find "The Patents and Designs Act, 1907," by J. Roberts and H. F. Moulton (price 4s.) useful. Shall we send you these?

Wireless Telegraph Notes.—According to the *Money Market Review*, Brazil will have the largest wireless telegraph system in the world by the end of 1911, no less than fifteen new wireless stations being now under erection along the Amazon and Paraguay by the United States Wireless Telegraph Co.

According to a British Consular report dealing with the trade of Uruguay for 1909, a small power Marconi wireless telegraph station has been established at Punta del Este, near Maldonado, which has a radius of 310 miles. Mr. Marconi is said to have under consideration the establishment of a large power station for communicating direct with Italy. The Ministry of the Interior have decided to accept the offer of a German wireless telegraph company, which is represented in Monte Video, for the erection of wireless telegraph stations in Uruguay. There are to be five land stations, three stations on battleships, two military transportable stations, and four flying transportable stations for army use. The prices are said to be as follows:—Land stations, with a range of 800 km., £3,810; 500 km. range, £2,350; vessel stations, 400 km. range, £950; 100 km. range, £537; transportable military stations, 200 km. range, £1,600; 60 km. range, £478. The total value of the contract is £16,397.

The action of the Australian Postmaster-General in giving a contract to the Australian representatives of the Telefunken system for wireless stations at Sydney and Fremantle has been considerably criticised in the Australian Parliament. It is now stated that the Australian Wireless, Ltd., have not signed the contract, and that the guarantors for the Company have not signed the guarantee. According to the *Australian Mining Standard* there is a strong feeling that the Marconi Co. should have been given the contract, in spite of a considerable difference in price, this argument being mainly based upon the question of patent rights in connection with which the Marconi Co. is fully protected in every country except Germany, whilst the Telefunken Company were said to have no patent rights outside Germany. Whilst on the one hand it was suggested that the Australian representatives of the Telefunken Co. are not financially strong enough to carry out the contract, the chairman of that Company, which was specially formed in connection with the Australian contract, has written a letter stating that the Company is anxious to proceed with the contract, but that some indecision on the part of the Government as to the exact site is the cause of the delay.

According to the *Board of Trade Journal*, the South African Government have entered into a contract with Marconi's Wireless Telegraph Company for the erection of a wireless telegraph station at Slanakop, near Kommetje, on the coast of the Cape Peninsula, which is to have a day range of 400 miles and a night range of from 600 to 1,000 miles. The capacity of the station is 5 kw.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

DEPRECIATION.—We have received a copy of the second edition of a useful booklet, entitled "Depreciation of Works and Machinery: its Causes, Effects, and Treatment," by Mr. H. Sherley-Price, senior partner in the firm of Wheatley, Kirk, Price & Co., engineering valuers (46 Watling Street, E.C.). The depreciation of works or factory buildings as well as machinery are clearly dealt with, and the necessity for dealing with every case on its merits is emphasised. Complete revaluation is often preferable to the writing off of fixed arbitrary percentages.

CONDUITS.—A new and revised price list of steel conduits and conduit fittings, much more comprehensive than the old list which it supersedes, is to hand from Messrs. Siemens Brothers' Dynamo Works, Ltd. (Supplies Department, 39 Upper Thames Street, E.C.).

RESISTANCE MATERIALS.—A booklet on this subject is being issued by the Driver Harris Wire Co. (sole British agents, Messrs. Denman, Glover & Cooper, 429-431 Corn Exchange Buildings, Manchester). This contains well-arranged tables of particulars of a considerable number of resistance materials, including two special new alloys known as "Yankee Silver" and "Therlo," which the company have recently introduced.

ISOLATING SWITCHES.—A new leaflet from Messrs. A. Reyrolle & Co., Ltd. (Hebburn-on-Tyne), gives particulars, prices, and dimensions of a series of isolating switches for pressures up to 10,000 volts, arranged for operation by a hook on an insulating pole.

ARC LAMP LOWERING GEAR.—Messrs. J. & H. Grevener (Eldon Street House, E.C.) have sent us leaflets describing a new pattern of self-sustaining safety arc lamp winch and arc lamp coupling. The winch is simple in construction and is governed by an automatic brake, so that it remains locked in any position when the handle is taken out, and the coupling, which is quite weatherproof, locks itself automatically and takes all strain off the rope when the lamp is in place.

INSULATING VARNISH.—A leaflet from Chas. H. Blume (Western Road, Mitcham, Surrey, and The White Building, Sheffield) calls attention to a range of insulating varnishes which this firm have perfected as the result of considerable research and practical experience. These varnishes, which entirely prevent the absorption of water by the materials treated with them, are known respectively as "Megomac" and "Insulac." The former is a clear and the latter a black varnish, and both are made in three grades for stoving, air-drying, and finishing respectively.

CALENDARS, &c.—A clear, boldly printed office calendar with monthly tear-off sheet is being issued by the United Flexible Metallic Tubing Co., Ltd. (112 Queen Victoria Street, E.C.).

Messrs. Pooley & Austin (25 Victoria Street, S.W.) are sending to their friends with their New Year's wishes a convenient flexible office desk ruler, which will also serve as a reminder of the articles for which they are most anxious to receive inquiries.

THE TELETHERMOMETER

A SYSTEM for the electrical measurement of temperature at a number of different places from a central position, and especially designed to meet the requirements of cold stores and the refrigerating compartments of steamships, has been introduced by Nalder Bros. and Thompson, Ltd. (34 Queen Street, London, E.C.). Resistance coils enclosed in metal cylinders open to the atmosphere are mounted in the various compartments, and are connected by means of lead-covered cable to a multiple contact switch and an indicating instrument of the moving-coil pattern. To ascertain the temperature in any particular compartment, the corresponding resistance coil is connected by means of the switch to the indicator and a source of constant pressure. The temperature is read off direct on the dial of the instrument. For cold storage work, special attention is paid to the calibration of the scale between 29° and 40° Fahr., and accuracy is guaranteed to within half a degree with certain ranges. Either a potentiometer resistance connected across the lighting supply or a special form of magneto-generator is used for the source of current; a steady pressure of 30 volts D.C. is required.

This system has recently been installed at a large cold storage depôt in London. Resistance coils are placed at ten points and are all connected to an indicator in the manager's office. The source of current is a potentiometer coil connected across the 230-volt public lighting supply. The guaranteed accuracy of within half a degree has, it is stated, been substantiated by careful tests. The system enables accurate and regular records of the temperatures to be kept with the minimum of time and trouble.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published January 26th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

30,556/09. **Variable Speed Polyphase Driving Gear for Ships, &c.** H. A. MAVOR, H. M. HOBART and MAVOR & COULSON, LTD. This patent covers a system in which two or more motors with means for varying their pole numbers, are supplied with currents of different phase-numbers and frequencies from two or more generators. At maximum load all the machines and the different windings are used at their full capacity without interfering with each other. An important feature is that synchronising of the generators is avoided. Various windings and connections are described. Nineteen figures.

12,483/10. **Flame Arc Lamps.** SIEMENS-SCHUCKERTWERKE GES. In order to remove the fumes from the globe of a flame arc lamp, an annular passage with outlets in the upper part of its outer wall is provided above the globe. Screens or rotary cowls are fixed outside over these openings, so that wind striking the lamp may set up a suction effect. Six figures.

13,311/10. **Fuse Holder.** V. G. MIDDLETON and C. J. BAKER (London). A totally enclosed fuse holder of the handle pattern with contact blades at each end, consists of an insulating tube, in the ends of which are terminals for gripping the fuse wire without the aid of screws. Caps, which fit over the ends of the tube, serve both to grip the wire and to close the tube. Five figures.

18,528/10. **Fuse.** SIEMENS-SCHUCKERTWERKE GES. To prevent the setting-up of an arc in a cartridge fuse, in which a short main fuse wire is connected in parallel with a longer auxiliary wire to take the final arc, the two wires are arranged in the same casing, but are separated by a screen of insulating material, which divides the casing into two compartments. Four figures.

22,224/10. **Instrument for Indicating Equalising Currents of Alternators in Parallel.** SIEMENS BROS. & Co., LTD. (*Siemens and Halske A.-G.*). The primary coils of a current transformer are inserted in series between the common 'bus-bar and the circuit of similar phase of each generator, and the secondary coils are connected in series with one winding of the phase-difference indicator of that generator. The other winding of the phase instrument is traversed by the resultant current due to the sum of the separate currents flowing in these secondary coils. Four figures.

28,661/10. **Reversing of Polyphase Motors.** SIEMENS-SCHUCKERTWERKE GES. To avoid sparking at the switch contacts and heavy rushes of current when reversing three-phase induction motors of low frequency, the field is maintained near its full strength during reversing by first short-circuiting the two phases to be reversed at the instant when they are at equal potential. One figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: SAUVAGE [Projectors] 378/10; SIEMENS-SCHUCKERTWERKE GES., 5,452/10; SIEMENS BROS. DYNAMO WORKS and NEBEL [Search-light projector lamps] 15,018/10.

Distributing Systems, Cables & Wires, Insulating Materials, &c.: BERRY [Transmission and distribution systems] 23,179/09; BURGESS and CLARK [Apparatus for cleaning wire] 9,673/10.

Dynamos, Motors, & Transformers: LYNDON [Variable-speed dynamo (train-lighting) distribution system] 649/10; A.-G. BROWN, BOVERI & CIE. [Compensating winding for polyphase commutator machines] 1,768/10; HEATHER [Control of slip-ring induction motors] 9,304/10; MARKS (*Felten & Guilleaume-Lahmeyerwerke A.-G.*) [Motor control] 10,370/10; SIEMENS BROS. & Co. (*Siemens & Halske A.-G.*) [Current transformers] 25,732/10.

Electric Ignition: HOSCH and MORREL [Sparking-plug] 2,186/10; SUSSEX, 23,241/10.

Electrometallurgy & Electrochemistry: REID [Electric furnaces] 1,189/10; SMITH and DEAKIN [Electrodeposition of metals] 7,224/10; RUTHENBURG [Electric furnaces] 20,404/10.

Incandescent Lamps: BENNETT [Lamp sockets] 5,926/10; KRAUSE [Metal-filament lamps] 11,107/10; SCHRÖTER [Metal-filament lamps] 15,879/10.

Instruments & Meters: MACALISTER [Apparatus for determining position of faults on mains] 7,574/10.

Storage Batteries: STERN, 11,781/10.

Switchgear, Fuses, and Fittings: WINTERBOTTOM [Lamp-holders] 472/10; PARKINSON and WOODALL [Conduit joints] 658/10; SYKES & SUGDEN, LTD. [Double-break switches] 8,460/10; SMITH [Battery connectors] 9,617/10; THOMPSON (*Porter*) [Motor controllers] 15,548/10.

Telephony and Telegraphy: THOMPSON (*Morse Code Signal Co.*) [Electromagnets for signalling apparatus] 671/10; AITKEN and BRITISH INSULATED & HELSBY CABLES, LTD. [Telephone switchboards] 1,050/10; THOMPSON (*Deutsche Telephonwerke Ges.*) [Automatic telephone exchanges] 12,248/10.

Traction: HAMILTON [Suspended railways] 886/10; MOORE and CROMPTON [Safety devices for trolley-wires] 903/10; OWEN [Ventilation of tramcars, &c.] 2,538/10; SPENCER [Vacuum brakes] 3,503/10; WOODYER [Route indicator] 10,333/10; MONARD [Control of points and signals] 15,292/10; ALLGEMEINE ELEKTRICITÄTS GES. [Selenium cell signalling apparatus] 17,156/10; SIEMENS BROS. & Co. (*Siemens & Halske A.-G.*) [Signalling circuits] 20,326/10.

Miscellaneous: BRENNAN [Gyroscopic stability mechanism] 26,034/09; HARVEY PNEUMATIC CLEANERS Co. [Vacuum cleaners] 1,058/10; STOTHERT & PITT, LTD. [Electric cranes and winches] 3,462/10; SERRELL [Vacuum cleaners] 4,966/10; GAUCHER [Air-compressors adapted to work as vacuum pumps] 9,591/10; ALLGEMEINE ELEKTRICITÄTS GES. [Emergency braking devices] 25,589/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Electrochemistry, &c.: HEIL [Galvanic batteries] 207/11.

Incandescent Lamps: ATWOOD, 23,535/10.

Miscellaneous: MERSHON [Formation of dielectric films] 28,352/10; FISKER [Portable electric vacuum cleaner and blower] 30,058/10; BECKER [Reducing loss of energy in lines with variable electro-magnetic equalising] 65/11; MERSHON [Insulating devices] 239/11; ALLGEMEINE ELEKTRICITÄTS GES. [Centrifugal pumps] 431/11.

Application for Restoration of Patent

530/07. **Copper Refining.** L. JUMAU. Application has been made for the restoration of this patent, which expired last June owing to the non-payment of renewal fees. It covers a chemical process for obtaining a copper precipitate from a copper salt solution. The precipitate is then compressed into briquettes, which are used as anodes in ordinary electrolytic refining vats to eliminate the precious metals.

Surrender of Patent

18,328/09. **Flame Arc Lamp.** SIEMENS-SCHUCKERTWERKE GES. This patent was revoked on Jan. 17th, as the result of an offer to surrender by the patentees. It covers a lamp with three carbons, two of which support each other and contain the salts, the third being a plain carbon.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

2,818 of Feb. 3rd, 1897. **Mercury Meter.** S. Z. DE FERRANTI. This patent covers the use of a gland in mercury motor meters to enable them to be transported with the mercury in them. The first claim is:—"In an electricity meter using mercury, retaining the mercury in position by the use of a gland through which the spindle passes freely during work, and which gland is capable of being closed when desired."

2,904 of Feb. 3rd, 1897. **Telegraphy.** F. L. MUIRHEAD. This relates to perforators for automatic tape transmitters, and covers a construction in which the punches and cutting plates are mounted on a removable base-plate for facilitating sharpening or adjustment.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: F. M. LEWIS [Converging-carbon lamp mechanism] 20,609/05.

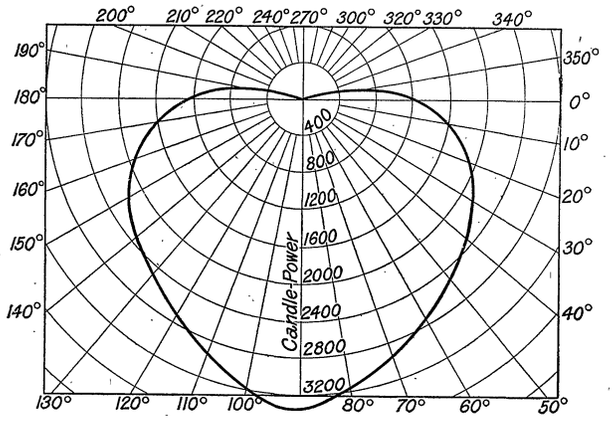
Distribution Systems, &c.: G. WILKINSON [Cable junction boxes] 20,497/01.

Dynamos, &c.: W. E. BURNAND [Air-cooled transformer] 20,423/01; R. VON LIEBEN and E. REISZ [Electric variable-speed transmission gear] 21,795/04; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [High-speed rotor field magnets] 22,157/04; V. A. FYNN [Combined series and repulsion A.C. commutator motor] 20,368/05.

Incandescent Lamps: W. NERNST [Heating wire and automatic cut-out for Nernst filament] 23,470/97.

Switchgear, &c.: G. C. MARKS (*J. Roberts, Durban*) [Limit switch for dimming lamps] 20,666/05.

Telephony, &c.: V. POULSEN [Variable-capacity condenser for wireless systems] 20,068/05; I. KITSEE [Twisted conductors of telegraph and telephone systems] 20,547/05.



Traction: F. R. JOYCE [Brake blocks] 20,584/99; A. B. UPHAM [Trolley poles, &c.] 22,097/03; H. JAMES [Trolley wheels] 21,648/04.

Miscellaneous: J. TINSLEY [Coal-cutters] 22,042/02; T. BAMFORTH [Smoke consumption] 20,652/05.

A NOVEL ARC LAMP

An arc lamp of extreme simplicity, looking at first sight like a resuscitation of the Jablochkoff candle, but with an important new feature rendering it always self-starting, is shortly to be placed on the market in this country. We were permitted to be present at a demonstration of the apparatus by the inventor, Dr. Ruhling. As in the Jablochkoff candle, the two carbons are parallel, and are separated by a strip of non-conducting plaster, and a metallic bridge is provided for starting the arc. In the original lamp, if the current is interrupted, the arc cannot restart without restriking by hand; but in this invention, a certain amount of powdered copper is incorporated in the plaster, and when the arc goes out, a film of copper is deposited across the plaster, and forms the necessary bridge for restarting the arc. The reducing effect of the carbon in the arc prevents the copper

Polar Curve of Candle-power Distribution.

from oxidising. The lamp can be used in any position—vertically upwards like a true candle, horizontally, or with suitable carbons pointing vertically downwards in an economiser, with a blow-out coil, as a flame lamp. In the first two cases, absolutely no mechanism is required, and in the flame lamp the very simplest device is sufficient to permit the carbon to feed against a stop as burnt away. The sizes of the two carbons in the continuous-current lamps are proportioned so as to burn away at an equal rate, and we are informed that a steady light can be obtained with a current as low as 2·5 to 3 amperes.

The appended candle-power curve shows that the candle-power is a maximum in the axial direction, which would indicate that, with the carbons nearly horizontal, a distribution of light not unsuitable for street lighting can be obtained.

SYSTEMS OF WIRING

A DISCUSSION on Wiring Systems was held at a meeting of the Dublin Section of the Institution of Electrical Engineers, on Thursday, January 12th. Mr. T. Tomlinson was of opinon that no one system was applicable to all situations. Casing and capping had advantages where the materials, workmanship, and supervision were not of the best, because the wires were well separated from each other. It did not, however, make a cheap job if properly done. He considered close joint tubing was absolutely the worst system to employ under bad conditions. The wires were all bunched together, and might actually get burnt on to the tubing, there was great difficulty in jointing up the tubing, and wires were often left exposed at junctions, probably resting on a sharp edge. The use of screwed junctions was a distinct improvement, but was rather expensive. In that system, however, it was essential that the conduits be laid first and jointed up complete, the wires to be drawn in *after*. For this it was necessary to provide ample room, easy bends and proper draw boxes. Screwed tubing should be laid during the construction of buildings; it made a bad and unsightly job if done on the surface. He thought there were possibilities in the Stannos system, but it was very much handicapped because at present all supply authorities refused to connect it to their mains unless a transformer intervened. (Mr. Tomlinson evidently had in mind the form of the Stannos system where the sheathing is used for the return; there is, of course, no objection to the ordinary two-wire Stannos system.) Twin wire insulated with vulcanised rubber and lead-covered, made a neat and safe job under certain conditions. Paper insulation could also be used if care was taken in sealing up the ends; he believed, however, that this class of wire could now be obtained in which the insulation was not of so hygroscopic a character. He thought that lead covering was preferable to cheap and badly enamelled tubing.

Mr. Mark Ruddle (City Eectrical Engineer, Dublin) thought the most important requirement was absolute reliability. Wood casing systems put in some 16 or 18 years ago were still doing good service. Systems employing an "earthed" outer were quite unsuitable for connection to public supply systems.

Mr. Wainwright (Messrs. Meldon & Co.) mentioned that in his experience very few faults occurred on wires in wood-casing systems; he could not, however, say the same regarding close conduit; the trouble was usually due to water entering and collecting at the switches. More trouble, however, occurred with flexible cords than the main wires. The lead-covered system was good. Slip-tubing was the cheapest system, casing some 10 to 15 per cent. higher, while screwed tubing was too expensive for ordinary work.

Mr. S. W. Martyn described at considerable length his M. P. system (see Electrical Engineering, September 8th, 1910, page 574). He knew whole streets of houses in London which had been wired at 4s. 6d.—5s. per point.

Mr. J. Tierney (Dublin United Tramways Co.) drew attention to cheap wiring systems which he had seen very largely used on the Continent.

Mr. R. U. Eaton said that the cost of erecting casing was considerable as, in order to do a good job, it was necessary to employ carpenters. Slip tubing was cheaper, but damp plaster acted on it very rapidly. He had found 4—22 wires in a $\frac{5}{8}$ in. tube. Screwed tubing and 2,500 megohm wire made the best job, but 2,500 megohm wire was dear—especially if it wore the C.M.A. label. It was possible to buy wire apparently as good without the magic label some 40 per cent. cheaper. He considered that consulting engineers should specify the size of junction boxes to be put in. He had found lead-covered and paper-insulated wires unsatisfactory.

Mr. Wm. J. U. Sowter (Chief Electrical Engineer, Bray) mentioned that where paper-insulated wires were used it was quite common to see wall-paper saturated in oil which had escaped from the wires. Stannos wiring was only suitable for connection to public supply systems where a special transformer was used. He believed that in some cases two wires were used, each surrounded by the metal envelope, which was earthed. Such a system might do for direct-current supply, but was unsuited for alternating supply, owing to eddy currents being set up in the metallic casings.

Mr. A. E. Porte, in closing the discussion, thought it significant that a recent congress of Fire Brigade Officers unanimously decided that casing and capping was the safest system. He knew of a large job in a brewery on the slip-tube system, which had all been pulled out after a few months' working, the trouble arising from damp necessarily present. He considered that consulting engineers should specify the weight of tubing per foot run. He would suggest 14 B.W.G. as a standard gauge, but 15 B.W.G. was the thickest obtainable at present. Mr. Porte did not favour lead-covered wires on account of the necessary presence of mortar, which had a corrosive action on lead.

Coronation Illuminations.—The Associated Municipal Electrical Engineers, Greater London, have passed the following recommendation:—"That this Association recommend that the charge for current for Coronation illumination be on the basis of one penny per unit, with a minimum connecting and disconnecting fee of 5s., and, where the existing service is insufficient, the cost of additional service."

Institution of Electrical Engineers.—The following is the result of the ballot for new members on Thursday.—*Members:* H. A. Couves, S. B. Donkin. *Associate Members:* J. Alsing, F. Briggs, T. K. Evans, F. W. Francis, W. H. Freemantle, J. W. Heaney, D. F. McIntosh, F. McMorrough, E. E. Moore, E. W. Newton, P. A. Paris, T. D. Parry, G. Richman, G. Rogers, W. R. Rothenberg, W. V. Ryder, R. P. Stewart, J. D. White, W. N. Wilson. *Associate:* R. L. Goold. *Students:* J. V. Buckley, R. Cowell, D. H. Green, D. Harrop, F. C. Heayberd, S. Holmes, L. Hugo, P. S. Jackson, E. G. James, L. S. King, M. Kshirasagar, B. S. Lion, R. Nandi, A. Neilson, J. F. Perrin, C. E. Robertson, H. D. Shaw, H. C. Simmons, D. H. Smith, N. Steel, K. A. Ward, W. Woodrow.

Liverpool Tramways.—Mr. C. W. Mallins, General Manager, Liverpool Corporation Tramways, read a Paper on Friday evening last before a large audience in Liverpool on the Liverpool tramway system. He mentioned the pioneering experiments of G. F. Train at Birkenhead in 1860, and traced the history of the Liverpool undertaking from the incorporation of the company in 1865. After various vicissitudes, the lines were finally taken over by the Corporation in 1897, and their electrification was completed in June, 1901. Since then the increase in traffic has been enormous. Looking into the future, he expressed strong preference for tramways over tube railways for dealing with the traffic problem, and pointed out that the substitution generally of mechanical for horse traction was doing much to better the conditions, and he looked forward to a great future for the trackless trolley system.

Hosted by Google

LOCAL NOTES

Dundee: *Trolley Omnibus.*—Mr. Peter Fisher, the Tramway Manager, gave a lecture last week upon trolley omnibuses, which he considers could be adopted on certain routes in the neighbourhood of Dundee.

Falkirk: *Bulk Supply.*—The Council have decided to inform the Scottish Central Electric Supply Co. that, after the expiry of the present agreement for bulk supply on July 1st, no electrical energy will be required from the company.

Glasgow: *Tramways Assessment.*—The Tramways Committee's recommendation to appeal against the assessment has been referred back. The Committee claim that the law in Scotland is that a tramway should be rated as a railway, viz., upon the basis of 25 per cent. of the valuation. For two years an increased assessment has been levied, but the Committee think it is time they asserted what they are advised is their legal position. The object of referring the recommendation back was to give the City Assessor an opportunity to explain his reasons for the increased assessment.

L.C.C.: *Petitions against Bills.*—The Highways Committee recommend that petitions should be lodged against the following electrical bills in the coming Parliamentary session:—Central London Railway, London Electric Railway, Metropolitan District and Metropolitan Railways.

Electric Supply.—An agreement between the Poplar and Stepney Borough Councils for a mutual supply of electricity in times of emergency has been reported upon favourably by the L.C.C.

Bermondsey: Electric Supply Competition.—The Highways Committee of the L.C.C. have communicated with the Board of Trade concerning the application of the Bermondsey Council for an electric lighting provisional order in the portion of their area now supplied both by the London Electric Supply Corporation, Ltd., and the County of London Electric Supply Co. The County Council ask that the order should not be granted on the ground that it is very unusual to have three authorities supplying in the same area, that public inconvenience will be caused by the laying of a third set of mains, and that it would extend the area in which, after purchase of the companies, the L.C.C. will be in competition with the Borough Council. Should the order be granted, the L.C.C. call attention to a section which would give the Borough Council authority to sell electric fittings to persons other than consumers or prospective consumers.

Newport: *Electricity Finances.*—The Ratepayers' Association having threatened litigation in respect of the finances of the municipal electricity undertaking, the Town Clerk has been instructed to take counsel's opinion on the position. The questions involved are similar to those which arose in the action by the India Rubber, Gutta Percha & Telegraph Works Co., Ltd., against the West Ham Corporation.

Plymouth: *Electricity Estimates.*—The estimated revenue for the electricity undertaking for the year to March, 1912, is £26,585, compared with £24,750 for the current year, leaving a gross profit of £11,295, against £10,120 in the current years. For street lighting the Committee anticipate an expenditure of £6,946 against £6,916 for the current year.

Stoke-on-Trent: *Vibration from Electrical Machinery.*—The Stoke-on-Trent Ice & Cold Storage Co. have been summoned in respect of alleged vibration from the electrical machinery, at their works, by a tradesman whose premises adjoin those of the company. The County Court judge was reluctant to grant an injunction, as it might lead to the abandonment of an important industry. Consequently, the proceedings were adjourned to see if the parties could come to an agreement.

Sutton: *Street Lighting.*—There has been a long fight between the gas and electric lighting companies as to a renewal of the contracts for street lighting, both companies at present having a certain portion of the district to deal with. After much debate the Council have decided not to give either company any additional portion of the district; but the keenness of the competition has been such that the ratepayers will benefit considerably under the new contracts. Thus, in those side streets which are at present lit by 64-c.p. lamps, 100-c.p. lamps will be substituted without any additional cost. In the same way, the gas company have had to give better value for money.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Barking.—The Electricity and Tramways Department require a 250-kw. motor generator or rotary converter. Particulars from Electrical Engineer and tenders by February 15th.

Bedford.—Application is to be made for a loan of £22,837 for electrical extensions.

Doncaster.—A loan of £12,000 is to be applied for in connection with extensions at the Electricity Works.

Dublin.—A loan of £125,000 is to be applied for in connection with the electricity undertaking.

East Indies.—According to the *Board of Trade Journal*, the Netherlands Government are to erect several large electric cranes for operation in connection with the Ombilin mines in the Netherlands East Indies. It is said that machines of German make have been offered, but are not regarded as suitable.

Glasgow.—The Corporation have acquired land at Dalmarnock, at an estimated cost of £22,000, for the purpose of a new generating station.

Hastings.—A Local Government Board inquiry was held last week concerning a loan of £2,803 for additional mains. There was strong opposition by the local gas companies. The inquiry was concluded.

London: *Stepney.*—The L.C.C. Finance Committee recommend sanction to a loan of £3,060 for electrical extensions.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

GREATER LONDON.

Buildings on the southern side of Catford Hill, Lewisham. New Middlesex County Council Guildhall at Westminster.

Factory in Ryley Street, Bermondsey. Messrs. Grant and Co.

Ten houses, Melrose Avenue, Croydon. C. S. Banks.—Distillery and storeroom, Mitcham Road, Croydon.—Thirty houses, London Road. Alder & Wheeler.—Electric theatres, London Road and Brigstock Road. C. Spencer, 16 Camden Road, Croydon.

PROVINCES.

Barry.—Proposed new police station.

Bridlington.—Laundry at Infirmary. Architect's Office, Wellington Road.

Hull.—Tenders are invited by February 16th for the electric lighting of the Sidmouth Street Schools. Particulars from City Architect.—New Sanatorium. Hospital Sub-Committee.

Lancaster.—Elementary School on High Street Estate.

Manchester.—Extensions to Guardians' Schools, Swinton.

Merthyr Tydfil.—Infants' School at Lower Pentrebach.

Paisley.—New Post Office. H.M. Office of Works, Storey's Gate, London.

Perth.—Two large tenements in South Inch Terrace. Builder, M. Kerrigan.

Rochdale.—Alterations to Town Hall.

St. Albans.—Cinematograph theatre.

Sittingbourne.—New Post Office.

Swansea.—Cinematograph hall, High Street. W. Coutts.—Six houses, Waterloo Place. R. Lacy.—Eight houses, Monterey Street. James Taylor.—Seventeen houses, Beechwood Road. H. Jenkins.

Torquay.—New school.

Watford.—New Church and Institute in Whippendale Road.

MISCELLANEOUS

Birmingham.—The Tramways Committee require 1,700 tons of grooved steel girder tramway rails, and 3,000 pairs of fish-plates. Particulars from the Manager, and tenders by February 13th.

Blackburn.—Tenders are invited by the Electricity and Tramways Committee for stores, including insulating material, house service fuse-boxes, switches, &c., motors, motor starting switches and screwed tube for inside wiring. Particulars from Electrical Engineer and Tramways Manager and tenders by February 13th.

Salford.—Tenders are invited by February 13th for a year's supply of stores to the Electricity Department, including cables, cable accessories, bitumen, cable conduits, service fuse-boxes, meters, maximum demand indicators, gravity type

ammeters, circuit breakers and ironclad switches, switches, fuses and arc lamp globes, carbon filament lamps, arc lamp carbons and motor carbon brushes, motors, and motor starters. Particulars from Borough Electrical Engineer.

TENDERS RECEIVED AND ACCEPTED

London: *L.C.C.*—The following were received for the electric lighting of the Fire Brigade Headquarters extension :—Pinching & Walton, £460 17s.; G. Weston & Sons, Ltd., £525; Foote & Milne, Ltd., £528 10s.; E. Newbald & Co., £545 10s.; Lund Bros. & Co., £621 10s. The first-named tender has been accepted.

For the supply of workshop motors at the chief station of the Fire Brigade, the following have been received :—Verity's, Ltd. (recommended), £158 18s.; Lancashire Dynamo and Motor Co., Ltd., £182 4s.; General Electric Co., Ltd., £193 5s.; Mavor & Coulson, Ltd., £195 10s.; Electromotors, Ltd., £197.

The tender of Messrs. Stanley Bros. for 500,000 stoneware cable ducts for the Tramways Department, at £4,487 10s., is recommended for acceptance.

A contract is to be entered into with the British Thomson-Houston Co., Ltd., for the provision of 40 pairs of mercury-type ampere-hour meters for tramcars, at £200, and for the maintenance of same at 5s. per meter per annum

The tender of the Edison & Swan United Electric Light Co., Ltd., accepted by the L.C.C., and mentioned in our last issue, was for wiring material only, and not for fixing.

The Diesel Engine Co., Ltd., has recently received the following orders :—Hoffman Manufacturing Co., Ltd., Chelmsford, one 330 B.H.P. engine, with 220 kw. generator. Athlone Wool Mills, Ireland, one 240 B.H.P. engine. The Smithfield Markets Electric Supply Co., Ltd., three 270 B.H.P. engines, with 180 kw. generators. Barking Urban District Council, one 600 B.H.P. engine, with 400 kw. generator. Linoleum Manufacturing Co., Ltd., Staines, two 200 B.H.P. engines, with 135 kw. generators. Colombo Tramway Co., Colombo, one 525 B.H.P. engine, and 375 kw. generator. Canadian Government for pavilion at "Festival of Empire" Pageant at the Crystal Palace, one 200 B.H.P. engine, with 135 kw. generator, and one 120 B.H.P. engine, with 80 kw. generator.

London Electric Supply Companies' Dispute.—What promises to be an interesting action was mentioned before Mr. Justice Joyce in the Chancery Division on Friday, when the London Electric Supply Corporation, Ltd., sought to restrain the Westminster Electric Supply Corporation from soliciting or attempting to entice away the former's customers. In ELECTRICAL ENGINEERING for October 21, 1909, we gave particulars of an agreement between the two companies, under which the London company placed the management and working of the portion of their undertaking in Westminster in the hands of the Westminster company, upon certain terms. It is now alleged that the Westminster company have violated the terms of this agreement, although it was not made clear in what way. Both sides agree that it is a case which must be tried by the Courts, but the object of the motion was to secure that the Westminster company should not solicit the customers of the London company in the meantime. It was agreed that no further circulars should be sent out by the former pending the trial.

Tantalum Lamps for Tramcar Lighting.—An investigation has been carried out by the Chicago Railways Company in regard to "Tantalum" lamps, the object being to ascertain the proper allowance for renewals, energy economy, and correct voltage rating of lamps for street-car service. It was shown that in the case of a car burning twenty-five 16-c.p. "Tantalum" lamps, as compared with a similar equipment of carbon lamps, there was a saving of 1,301-kw. hours in energy on the basis of 1,800 hours lamp-burning a year, while a test extending over 600 car-months showed the renewals of carbon lamps to be 4·269 per car-month, and of "Tantalum" lamps 2·21 per car-month. The *Electric Railway Journal*, in analysing the results, shows that there was an average saving of 2·5d. per car-day on the basis of 1,800 hours of illumination per car-year, and that when "Tantalum" lamps have been installed in all the cars operated by the company there will be a saving of about £5,000 a year. The higher cost of "Tantalum" lamps over carbon lamps is claimed to be balanced at the end of the first year by the longer life of the metal filament. The saving in the current consumption is important in the case of the Chicago Railways, as the company purchase the power and pay a premium on peak loads.

APPOINTMENTS AND PERSONAL NOTES

Mr. C. A. Park, late carriage superintendent of the London and North Western Railway, has been appointed managing director of the British Westinghouse Electric & Manufacturing Company's works at Old Trafford, Manchester.

Mr. Arthur Wright has given six months' notice terminating his engagement as Consulting Electrical Engineer to the Brighton Corporation. Mr. Wright is now giving much attention to the undertaking of the Victoria Falls and Transvaal Power Co., to which concern he is Joint Consulting Electrical Engineer. His connection with Brighton extends over some twenty years, first with the old Hammond Co., and later with the Corporation. He designed the first power station, viz., North Road (now a sub-station), and also the Southwick Works, which were opened in 1906.

The Bradford Electricity Committee recommend that the salary of the City Electrical Engineer, Mr. T. Roles, shall be increased from £600 to £700 per annum as from April 1st, with two annual increases of £50 each, making a maximum of £800 per annum.

One hundred and twenty applications were received for the post of Burgh Electrical Engineer at Falkirk, rendered vacant by the resignation of Mr. John McMillan, who is going abroad. The salary is £200 per annum.

Mr. A. J. Newman has been appointed Mains Superintendent in the Bristol Electricity Works, at a salary of £180, rising to £200 per annum.

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £57 5s. to £57 15s. per ton (last week, £57 10s. to £58).

Bankruptcies.—A scheme of arrangement in the bankruptcy of Mr. Robert Brown, Parliament Chambers, Great Smith Street, Westminster, by which 7s. 6d. in the £1 will be paid on liabilities of £2,164, has been sanctioned. The debtor for four years acted as manager to the Traction Corporation, Ltd., and his insolvency is attributed to his liability for costs on an action brought by himself and the company in connection with an alleged infringement of an electrical patent.

A. J. Dale, electrician, 15 New Oxford Street, London, has been adjudicated bankrupt. The first meeting of creditors took place at Bankruptcy Buildings, Carey Street, London, on January 30th, and the public examination will take place on March 1st.

Siemens' New Telephone Numbers.—Messrs. Siemens Bros. Dynamo Works, Ltd., Incandescent Lamp and Fittings Department, Tyssen Street, Dalston, N.E., advise us that in future their "Dalston 4" line will be cancelled, this line having been replaced by three lines on the Dalston Exchange. With the three Central lines, there will be a range of six lines, the numbers being as follows :—Central 8387, 8388, and 8389; and Dalston 2440 (three lines).

Change of Address.—The offices of the Horsfall Destructor Co., Ltd., have been removed from No. 15 to more commodious premises at No. 17, Victoria Street, Westminster, S.W.

Reyrolle's Foremen's Dinner.—The foremen and deputy-foremen of Messrs. A. Reyrolle & Co., Ltd., of Hebburn-on-Tyne, held their annual dinner at the Ellison Hotel, Hebburn, on Saturday. Mr. W. A. Harrison, works manager, occupied the chair, and a very pleasant evening was enjoyed.

Theft.—At the Exeter Assizes on Monday, Arthur Wall, an electrical fitter at the Devonport Dockyard, was sentenced to six months' imprisonment for embezzling the funds of the Electrical Workers' Help Club at Devonport. The sum of £81 was involved out of a total of £144 which were received.

Train Telephony.—The "Railophone" system of train telephony by magnetic induction, devised by Mr. H. von Kramer, and described in ELECTRICAL ENGINEERING, Vol. VI., pp. 513 and 590, is to be given a trial on a ten-mile section of the Stratford-on-Avon and Midland Junction Railway.

OSRAM·LAMPS

Hosted by Google

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

British Columbia Electric Railway Co.—Interim dividend at the rate of 5 per cent. per annum on non-cumulative preferred ordinary stock for December half-year, together with a bonus of 1 per cent.

Siemens-Schuckert Co.—The *Times* states that this company is receiving an advance of £1,500,000 from Messrs. Siemens & Halske, and from Messrs. Schuckert & Co.

Blackpool & Fleetwood Tramroad Co.—Dividend at the rate of 9 per cent. per annum, placing £3,500 to depreciation, £750 to reserve, and carrying forward £2,642.

St. James & Pall Mall Electric Light Co.—Final dividend on the ordinary shares, making 10 per cent. per annum for 1910.

Cuban Telephone Co.—Subscriptions are invited for an issue of £300,000 five per cent. first mortgage gold bonds at 89.

Urban Electric Supply Co.—An extraordinary general meeting was held last week to consider a new agreement with Messrs. Edmundsons Electricity Corporation, Ltd. Mr. P. D. Tuckett, who presided, said that the agreement under which Messrs. Edmundsons managed the business of the Urban Electric Supply Co. had expired, and a new agreement was proposed for them to continue the management at an annual fee of £2,000. They were also to carry out all new construction work at cost price plus 10 per cent., and to finance the Urban Co. to the extent of a further £100,000. The agreement was approved.

Liverpool Overhead Railway Co.—Dividend at rate of 1½ per cent. per annum on ordinary shares for the December half-year, carrying forward £4,246.

London Electric Railways Co.—Dividend at rate of ¾ per cent. per annum upon ordinary stock for December half-year.

National Telephone Co.—Dividend at the rate of 6 per cent. per annum on the deferred stock for the December half-year, carrying £200,000 to reserve, and about £12,000 forward.

Metropolitan Railway Co.—At the meeting last week special attention was called to the fact that £10,000 had been transferred out of the half-year's revenue to the electrical renewal and depreciation fund, as against £5,000 twelve months ago. Automatic electric signalling has now been installed as far as Willesden Green.

Great Northern & City Railway Co.—The net revenue for the December half-year was insufficient by £3,903 to meet the fixed charges, and this sum has been provided from outside sources. The number of passengers carried was 5,856,829, against 5,652,556 in the corresponding period of 1909.

Anglo-American Telegraph Co.—A balance of £2,609 is carried forward from 1910, after meeting dividends of 3¾ per cent. on the ordinary stock, 6 per cent. on the preferred stock, and 1½ per cent. on the deferred stock.

City & South London Railway Co.—Mr. C. B. Stuart Wortley presided at the annual meeting on Tuesday. Although more passengers have been carried, the revenue per passenger was less for the half-year, owing to an increase in the through traffic with other railway companies. He referred to the speeding up of the trains to the average of 17 miles, which is now the speed on many of the other underground railways. On the City & South London, the average is only 13½ miles per hour, and an increase to 17 miles would necessitate great changes and additions to their rolling stock, and also considerable increase in siding accommodation. Nevertheless the public seemed to expect the increase in speed to become general, and it might be possible to save some portion of the expense of the new stock by ceasing to run five-coach trains in the less busy parts of the day, which at present they were obliged to do owing to the lack of siding accommodation and difficulties connected with the coupling and uncoupling of the coaches. The company had received representations from the municipal bodies in favour of extending the line beyond the present terminus at Clapham Common.

NEW COMPANIES

T. H. BROOKER, St. Michael's House, St. Michael's Alley, London, E.C. Capital £5,000. Electrical engineers.

MONTREAL TRAMWAYS & POWER CO., 4 St. Mary Axe, London, E.C. Capital, £4,000,110. To construct, purchase, lease or acquire tramways and street railways in Canada; to supply electricity, and to adopt an agreement with the Imperial Trust Company of Montreal.

MAGNET GALVANISING AND PLATING CO.: 82 Victoria Street, London, S.W. Capital, £30,000. Electrical engineers, contractors, electrometallurgists, galvanisers, &c. To adopt an agreement with S. O. Cowper-Coles, the Cowper-Coles Engineering Co., Ltd., and the Cowper-Coles Galvanising Syndicate, Ltd.

LA REGIONALE ELECTRIQUE DE L'ORNE: 1 Broad Street, Finsbury Circus, London. Capital £24,000. To construct electricity works, &c., in the Department of the Orne and neighbourhood, and elsewhere in France.

SCIENTIFIC ILLUMINATION: Registered by Messrs. Jordan & Son, 116 Chancery Lane, London, W.C. Capital £5,000. Electricians, and suppliers of electricity, &c.

From CONSTABLE'S List.

Part I.—Maxwell's Theory and Hertzian Oscillations, by H. POINCARE; translated by F. K. VREELAND. Part II.—The Principles of Wireless Telegraphy, by F. K. VREELAND. Diagrams. Demy 8vo. 10s. 6d. net.

10, ORANGE STREET, W.C.

TWIN GRIPS.—63 Bishopsgate Street, E.C. Capital £2,000 (1,500 preferred and 500 deferred). Electricians, etc., and to acquire from H. E. Evans an invention relating to an electrical fitting. The subscribers include P. C. Austwick, 423 Birkbeck Bank Chambers, London.

BASTIAN FOREIGN PATENTS: Registered by W. T. Hick, Broad Street House, London. Capital, £10,500. Dealers in electric heaters, cooking stoves, &c.

EMPIRE ALUMINIUM CO.—Registered by Ince, Colt & Ince, St. Benet Chambers, Fenchurch Street, E.C. Capital, £75,000 (25,000 preferred ordinary and 50,000 deferred). Manufacturers of, and dealers in, aluminium, and to adopt agreement with International Foil Co., Ltd.

ELECTRICAL POWER USERS ASSOCIATION.—This company has been registered with 100 members, each liable for £1 in the event of winding up. For insuring users of electric power against fire and other risks. The subscribers include O. Huxley, consulting engineer, 120 Coldershaw Road, Ealing, London.

Faraday House.—Mr. R. J. Wallis-Jones commences next week a course of demonstration lectures on electric welding to the senior students at the Standardising Testing and Training Institution, Faraday House.

Telegraph Traffic and Movements of Cable Ships.—The Compagnie Française des Cables Télégraphique has its West India system in order again, the last repair having been effected on December 27th, between Cape Haiti and Puerto Plata. On January 24th the cable between Dakar and Honakry was placed in working order again, but the following day the El Arich route was down. The lines of the Indo-European Telegraph Co. between Kertch and Soukhoum were down on January 26th for a short while. On January 28th the *Via* Hanekin route was interrupted between Bagdad and Hanekin, but was restored to working order on the following day. The *Via* Batoum route was interrupted between Trebizond and Batoum on that day also. The Indo-European Telegraph Co. again suffered derangement of the line between Kertch and Soukhoum-Kale on January 30th. The c.s. *Mackay-Bennett*, after having finished work in connection with the Havre-Waterville cable, is now in home waters, and expects soon to leave for her station, Halifax, N.S.

SUMMARY

A comparison of the estimated costs of manufacture of aluminium and copper low-tension, paper-insulated, lead-covered cables shows that aluminium cables should be cheaper than copper cables, and should effect a very considerable saving on the larger sizes. (Page 67.)

The Papers on high-tension transmission read recently at the London meeting of the Institution of Electrical Engineers, and to be discussed again to-night, have also been discussed in Newcastle and Manchester. (Page 68.)

Our monthly article on new electrical supplies and accessories contains announcements regarding some new sizes of metal filament lamps, and descriptions of several novelties, including an electrically heated towel-rail, a three-pin plug with an earthing contact for cooking apparatus, electric hair brushes and massage outfits, and an electric humidifier. (Page 69.)

A report of the discussion on Mr. P. V. Hunter's Paper on sub-station design, read recently before the Newcastle Local Section of the Institution of Electrical Engineers, is given. (Page 72.)

Some particulars are given of a new design of three-phase goods locomotive, forty of which are being constructed for use on the electrified main line sections of the Italian State Railways. The two motors are rated at 1,000 h.p. each, and two running speeds of 14 and 28 miles per hour are provided. (Page 71.)

At the annual dinner of the Institution of Electrical Engineers on Thursday, Mr. S. Z. de Ferranti said that the Council were considering whether the Institution could not be of greater utility to its members. He also spoke strongly against the "municipal idea" that no one should be allowed to make a profit out of the industry. (Page 73.)

The discussion upon library lighting, which has been taking place at the Illuminating Engineering Society was concluded on Tuesday last week. A feature of the discussion was the desire of librarians to have prepared for them a specification showing the proper illumination for different purposes. There was some difference of opinion as to whether there should be local lighting of tables, in addition to general lighting of the rooms, and suggestions were made with the object of avoiding certain difficulties now encountered in the wiring of new buildings. (Page 73.)

Among the Specifications published by the Patent Office on Thursday was one describing the stability mechanism of the Brennan mono-rail car. Two specifications covering details in the manufacture of metal filament lamps by O. Krause and K. Schröter respectively, are abstracted. R. A. Macalister describes a method of determining the position of faults on mains by means of a voltmeter and a wire brush in contact with the earth above the cable. A device for switching off traction motors automatically on the application of the emergency brakes, is covered by the Allgemeine Elektricitäts Ges. (Page 74.)

We give some figures relative to the dispute in Manchester regarding the smaller amount paid in relief of rates by the Electricity Department compared with the Gas Department. The Electricity Committee had to pay interest on nearly £1,000,000 more capital than the Gas Department, whilst in the case of about £1,000,000 expended in respect of the tramways no profit is made. (Page 75.)

The L.C.C. Highways Committee recommend that

Hosted by Google

the horse tramway lines in Liverpool Road, Islington, should be pulled up. There is much opposition.—£800 damages have been awarded against the Dublin United Tramways Co. in respect of a street accident.—The Manchester tramway employees have agreed to arbitration provided there is no question of reducing wages with the reduced hours.—Newcastle ratepayers are opposed to the running of trolley omnibuses.—The tramway extension from Paignton to Torquay, and the completion of the overhead lines in Torquay, will be completed in a few months.—In spite of the tender for electric street lighting at Holborn being the cheaper, it is proposed to adopt gas. (Page 75.)

EXTENSIONS to generating machinery are contemplated as follows: Aberdeen, £12,500; Bedford, £22,837; Heywood, £4,355; St. Pancras, £2,582; St. Helens, £10,800; Worthing, £7,000; and York, £15,000. —Two 100 kw. Diesel engine sets are required at Reigate; V.B. cable at Belfast; mains at Hackney; switchboard at Sale; and extension at the power station of Messrs. Bayliss, Jones & Bayliss, Wolverhampton.—Electrical and tramway stores are required at Belfast, Grimsby, and Leeds.—It is proposed to spend £1,000 at Bexley upon new tramcar brakes, and large expenditures upon tramway track reconstruction are contemplated at Nottingham and Burnley. (Page 75.)

ARRANGEMENTS have been made upon the Central London Railway for the separate lighting of the carriages in case of a failure at the power station.—Dividends have been announced as follows: St. James' & Pall Mall Electric Light Co., 10 per cent.; Central Electric Supply Co., 5 per cent.; Chelsea Electricity Supply Co., 5 per cent.; Westminster Electric Supply Co., 10 per cent.; Liverpool Overhead Railway Co., 1½ per cent.; South London Electric Supply Co., 5 per cent.; London Electric Railways Co., ¾ per cent. (Page 77.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, FEBRUARY 9TH.

Institution of Electrical Engineers.

8 p.m. Adjourned discussion on Long Distance Transmission Lines.

Institution of Electrical Engineers: Dublin Section.

8 p.m. At Royal College of Science.

Paint and Varnish Society.

8 p.m. At St. Bride's Institute, Bride Lane, Fleet Street, E.C. "The Application of Electrolytic Methods to Materials used in the Paint and Varnish Industry," by Dr. F. Mollwo Perkin.

FRIDAY, FEBRUARY 10TH.

Institution of Electrical Engineers: Yorkshire Section.

6.30 p.m. Annual dinner at Hotel Metropole, Leeds.

SATURDAY, FEBRUARY 11TH.

Institution of Electrical Engineers: Glasgow Section.

7.30 p.m. Annual Smoking Concert at the Grosvenor.

Junior Institution of Engineers.

6.30 for 7 p.m. Annual dinner at Hotel Cecil.

Birmingham and District Electric Club.

7 p.m. At Colonnade Hotel, New Street, Birmingham. "The Electric Incandescent Lamp," by J. Findlay.

MONDAY, FEBRUARY 13TH.

Institution of Civil Engineers.

8 p.m. At Great George Street, Westminster. Lecture on "Wireless Telegraphy," by Capt. H. Riall Sankey.

TUESDAY, FEBRUARY 14TH.

National Electrical Manufacturers' Association.

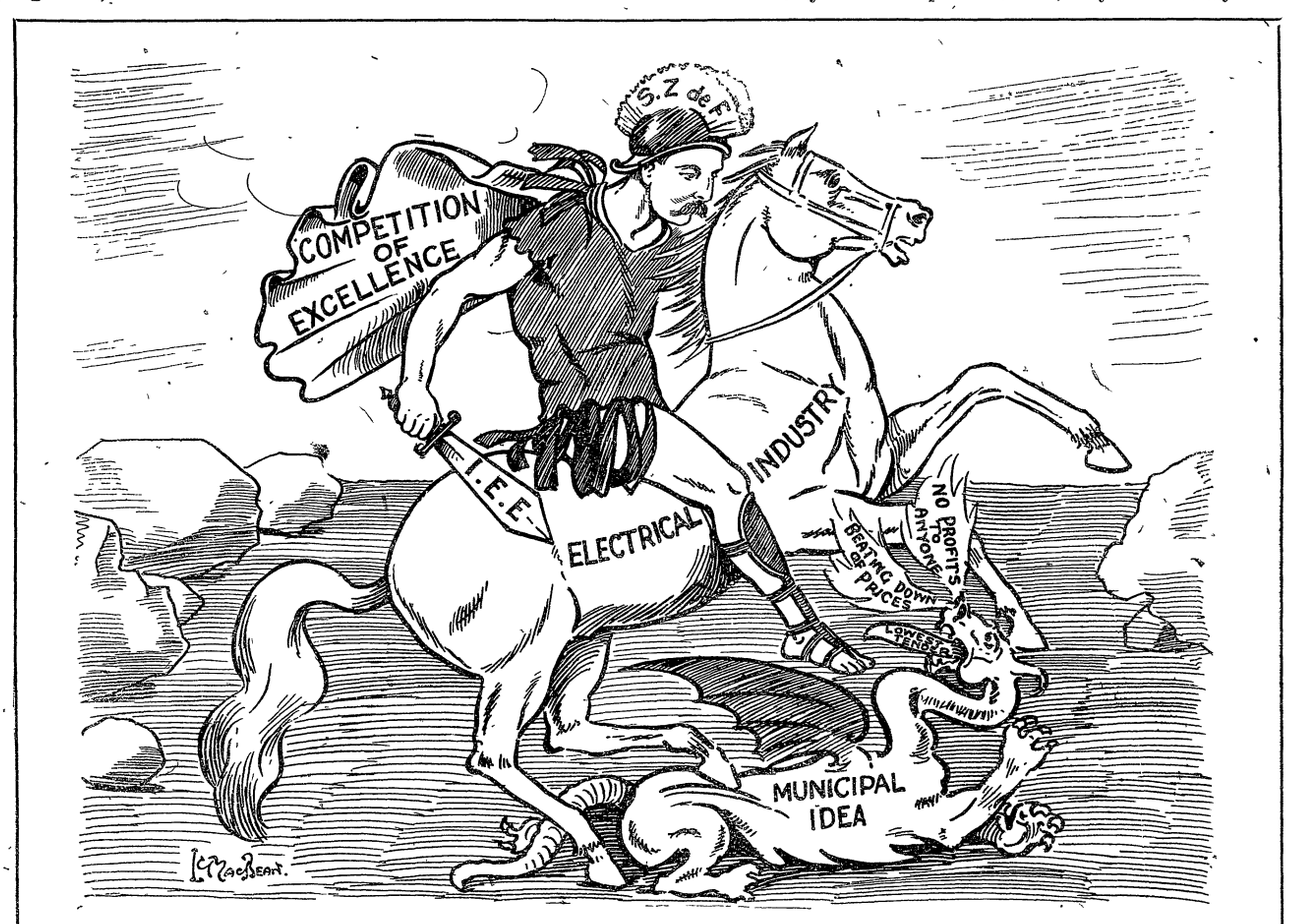
2.30 p.m. Committee meeting at Balfour House, Finsbury Pavement, London.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. At the University. "Chemical Action in the Windings of High-Voltage Machines," by A. P. M. Fleming and R. Johnson.

Institution of Electrical Engineers: Glasgow Section.

8 p.m. At 207 Bath Street. "Some Considerations Relating to the Parallel Working of Alternators," by the late Mr. J. R. Barr, introduced by Prof. F. G. Baily.



WEDNESDAY, FEBRUARY 15TH.

Institution of Electrical Engineers: Yorkshire Section.

7 p.m. At Leeds University. "Modern Long Distance Transmission of Electrical Energy," by W. T. Taylor, to be read by Mr. J. F. C. Snell.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. At Victoria Embankment. "The Manufacture of Dry Core Telephone Cables," by H. C. May.

See Mr. Ferranti's definition of the "Municipal Idea" at the Institution Dinner (page 73).

Hosted by Google

ALUMINIUM v. COPPER CABLES

In Electrical Engineering of November 24th, 1910, an article by F. C. Raphael and J. B. Sparks compared the relative costs of aluminium and copper cables for low-tension feeders on underground networks. It was pointed out that it should be possible, at the present prices of aluminium and copper, to buy single-core aluminium cables at a cheaper price than copper cables, of the same conductance, but the authors considered it unwise to quote actual prices for paper-insulated, lead-covered cable, owing to the present state of the cable market. Relative prices were, however, given for bitumen cables of various sizes.

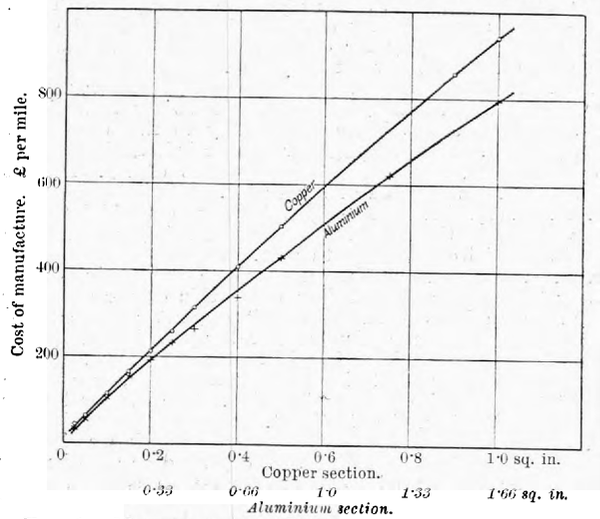


Fig. 1.—Manufacturing Cost of Copper and Aluminium Single-core, Paper Insulated Cables.

The authors have been urged to make this statement with regard to paper-insulated cables more complete, and although they are still loth to quote actual selling prices of cable, which are affected by so many considerations other than prime cost, they have made an approximate estimate of the manufacturing costs for both copper and aluminium cables on an identical basis. The table above gives some of the standard sizes of copper cable with aluminium equivalents, the overall diameters, approximate weights per mile, and estimated manufacturing costs. Copper is taken as costing £60 per ton (electrolytic wire bars c.i.f. port of arrival),

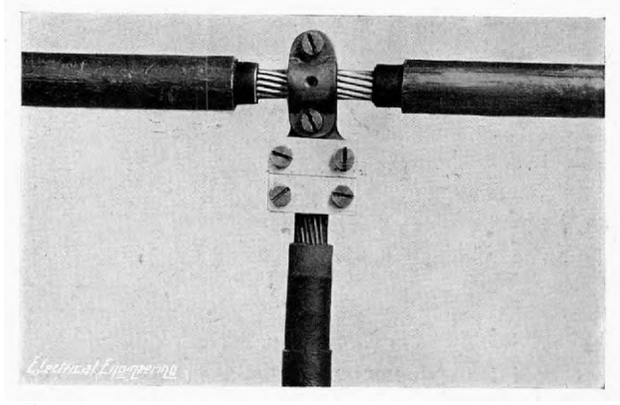

Fig. 3.—Aluminium Cable "Teed" off Copper Cable.

equivalent to drawn copper wire at 7¾d. per lb., and aluminium wire at 10d. per lb. at the cable works, which prices are approximately those at which the two metals are now obtainable. The radial thicknesses of dielectric and lead are assumed to be those specified by the Engineering Standards Committee for the diameters of conductor in question. Thus, for instance, in the case of 1 sq. in. aluminium equivalent to 0·6 sq. in. copper, the radial thicknesses that are employed for 1 sq. in. copper are assumed.

Standard Low Tension Paper-insulated Lead-covered Cables.

It is seen that for all sections, aluminium cable is cheaper to manufacture than copper cable, and that for the larger sizes the difference is very considerable. Thus, while the manufacturing costs for a 1 sq. in. copper cable amount to some £946, the corresponding figure for the equivalent aluminium cable is only £798, namely, £148 or over 15 per cent. less.

In Fig. 1 the same manufacturing costs are plotted in a pair of curves, which show very clearly how the saving due to the use of aluminium increases with the size of the cable.

It must be understood that the costs given are not those at which cable can be bought. They represent the bare manufacturing costs, including material, labour, &c., and no allowance is made for establishment charges, profit, or transport and other general charges.

The various methods of jointing were dealt with in the previous article. The accompanying photographs of copper to aluminium joints have been taken by the British Aluminium Co. Fig. 2 represents a straight-through joint. A three-part stepped clamp is used on

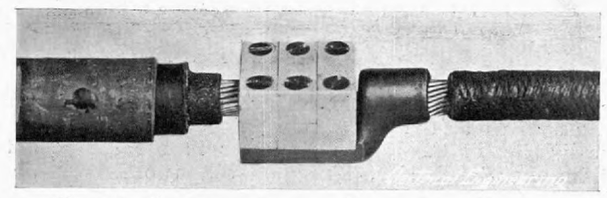

Fig. 2.—Straight-through Joint with Stepped Clamp on Aluminium Cable.

the aluminium cable, the clamping pieces being screwed down on to the flat lug of a thimble, into which the copper cable is sweated. A simple T-joint of an aluminium cable tapped off a copper cable is shown in Fig. 3. As before, the aluminium cable has a stepped clamp, which is screwed to the usual form of clamp on

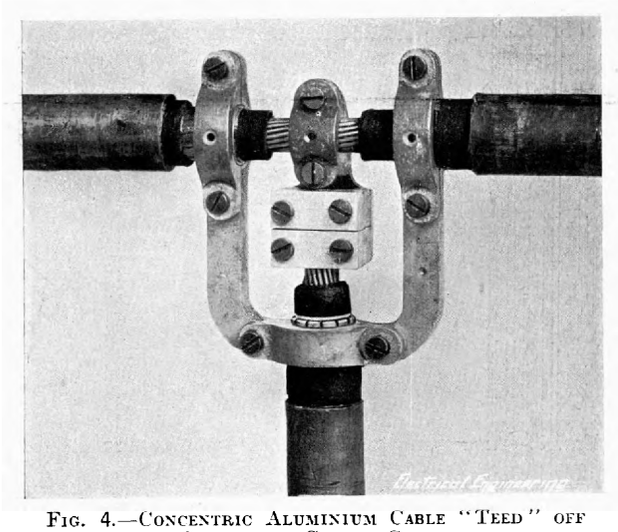

FIG. 4.—CONCENTRIC ALUMINIUM CABLE "TEED" OFF CONCENTRIC COPPER CABLE.

the copper cable. Fig. 4 illustrates a T-joint with concentric cables. A stepped clamp is placed over the inner of the aluminium cable, while a sleeve of aluminium is inserted between the outer strips and the paper insulation to protect the latter from the cutting action of the strips.

HIGH TENSION TRANSMISSION LINES

THE Papers on this subject by Mr. W. T. Taylor and by Messrs. R. Borlase Matthews and C. T. Wilkinson, read on January 26th, have been further discussed by the Local Sections of the Institution at Newcastle and Manchester.

The Newcastle discussion on Monday was opened by Mr. C. VERNIER (Newcastle-on-Tyne Electric Supply Co.) with a few remarks in favour of the Thury system. He also gave some figures of comparative costs for steel towers and wood poles, including first cost, erection, maintenance, and wayleaves, for a period of 36 years, assuming this to be the life of the steel tower, and 18 years that of the wooden pole. The cost per steel tower for 720 ft. span was £62, and for the equivalent number of wood poles for 240 ft. span, £63 18s. The necessity for voltages over 20,000 had not arisen in this country, but above 30,000 the suspension insulator was essential, and as it could swing, it lessened the stress on the towers. The shackle type of insulator had been abandoned by his company in favour of the pin type. He explained the action of the much criticised overhead earth wire, which to some extent counterbalanced the electrostatic charges induced by thunder clouds in the live wires. He thought that it was resonance that would probably limit the distance of transmission by A.-C. currents. The natural period for a line was approximately the speed of light in miles per second divided by four times the length of the line in miles. Thus a 400-mile line would resonate with the third harmonic at 40 cycles. With the high voltage, however, corona effects would greatly relieve the line from surges. The surge voltage when a current of C amperes was broken was independent of the length of the line, and could not exceed $200\sqrt{2}$ C. volts. In this respect the lower voltages and heavier currents had a less factor of safety. The authors of the second paper had stated that in long spans, the wires were prevented from touching by swinging in synchronism, but his own experience did not confirm this.

Mr. B. WELBOURNE (British Insulated & Helsby Cables, Ltd.) criticised some of the designs of towers shown, and held that the principal function of the earth wire was to earth all the metal-work on the poles. Flexible poles had been used for some years in the Midlands with success. He also referred to the advantages of aluminium for line conductors, and said that they were less liable to become coated with ice than copper.

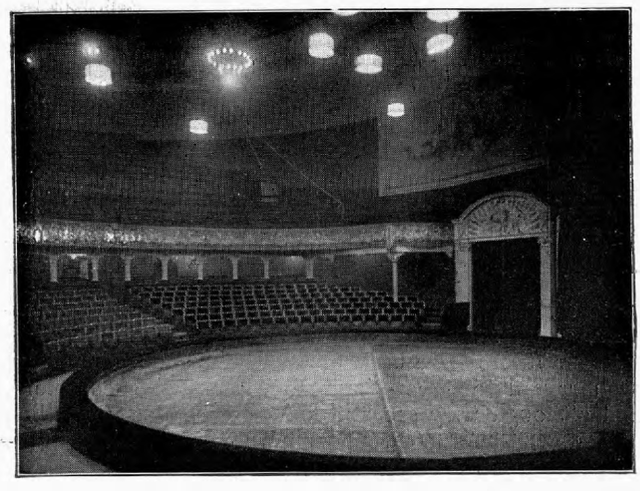
Some discussion then ensued on the life of creosoted wooden poles. Mr. A. G. E. DRUMMOND (National Telephone Co.) mentioned 40 years, and both Mr. ROBB (G.P.O.) and Mr. J. PIGG (N.E. Railway) had experience of poles lasting over 30 years. Mr. REDMAN (Messrs. Merz & McLellan) said that it was certainly too much to expect steel poles to last 36 years, and instanced steel-work which had only lasted seven years. Wooden poles were not suitable for conductors larger than 0·15 sq. in. in voltages above 20,000.

Mr. P. V. HUNTER (Messrs. Merz & McLellan) criticised the complications of some of the diagrams of connections, and Mr. J. ANDERSON (Newcastle-on-Tyne Electric Supply Co.) thought that on many such systems the relays would have to be tied up to enable the system to work at all. Messrs. Porter, Robinson, and Laws also spoke.

The discussion at Manchester was opened by Mr. J. S. PECK (British Westinghouse Co.). He did not quite agree with Mr. Taylor's ideas as to capacity and inductive effects, and called attention to the necessity for careful transposition in the case of the split conductors advocated by him.

Mr. W. CRAMP (Manchester Municipal School of Technology) wished to know whether the limit of 200,000 volts mentioned as now practicable was intended to apply to this country or only to America. He also asked for further information regarding corona losses, and made some criticisms of Mr. Taylor's presentation of his methods of calculation.

Mr. A. P. M. FLEMING suggested the use on high-tension systems of one of the three line conductors suitably earthed in place of a special overhead earth wire.



Mr. A. E. MALPAS referred to experiments on lessening corona losses by the use of a cable built up of a thin copper conductor wound round a hemp core. The split conductor method had been employed on the Lucar-Madrid transmission, where 20,000 h.p. was transmitted 300 km. at 60,000 volts, but he preferred complete duplicate lines on separate poles, as a breakdown of one line might affect the other. The overhead earth wire was not usual on the Continent.

Mr. J. LUSTGARTEN spoke of the way in which the limiting voltage from the corona point of view depended on the diameter of the wire, and referred to experiments with spheres. The explanation of the different voltage gradients necessary for breakdown of the air with different diameters was not clear. Again, when an actual brush discharge appeared, a larger voltage was required to maintain the ionisation. The humidity of the atmosphere had not appeared from his experiments to make any difference. He did not quite agree with Mr. Taylor's view that a flat disc insulator had a greater capacity than one with petticoats.

Mr. J. FOSTER thought that there was a great field in this country for long-distance transmission in connection with cheap power from surplus blast furnace and coke-oven gas.

METAL FILAMENT LAMPS AT A CIRCUS

FOLLOWING the lead of the majority of theatres and music halls which are now electrically lighted, an electrical installation has now been put in at Hengler's Circus, Glasgow, and full advantage has been taken of the excellent effect combined with economy that can be obtained with

OSRAM LAMPS AT HENGLER'S CIRCUS, GLASGOW.

Osram lamps. The accompanying illustration, which has been sent us by the General Electric Co., gives an idea of the lighting of the ring. The lamps in use comprise ten of the 1,000-watt size, nine 400-watt, two 100-watt, and 140 32-watt Osram lamps.

Tramways & Light Railways Association.—The annual general meeting will be held at the Gaiety Restaurant, Strand, London, on Friday, February 17th, at 7 p.m., and will be followed at 7.45 p.m. by the annual dinner and smoking concert.

The Special Committee on Speed Indicators submitted their final report on January 20th, and it will be published in the March issue of the Association Journal, the price of which will be increased to 2s. 6d.

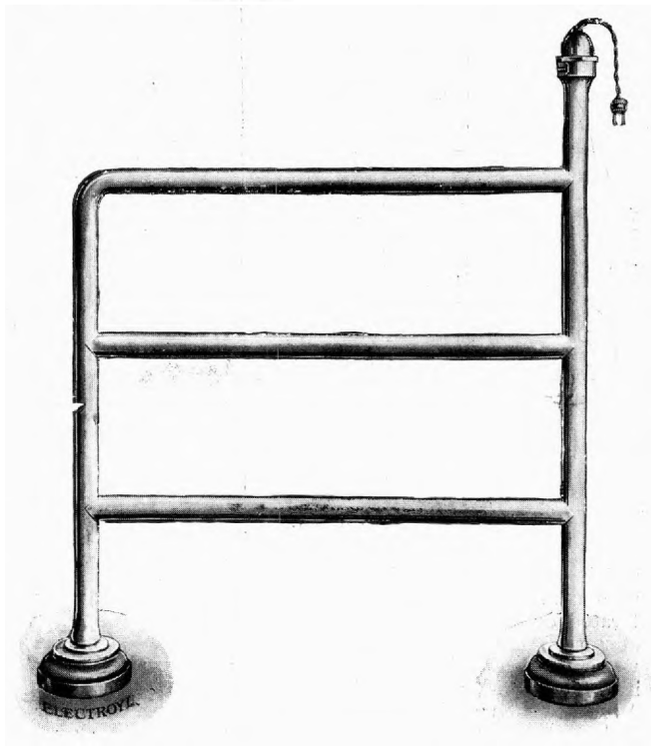
NEW ELECTRICAL SUPPLIES AND ACCESSORIES

Incandescent Lamps.

Siemens Brothers Dynamo Works, Ltd. (Incandescent Lamp and Fittings Department, Tyssen Street, Dalston, N.E.) announce that they are extending the range of their now well-known "One-watt" lamps by putting on the market a 400-c.p. size in a bulb 12 in. long by 8 in. diameter. These lamps have an efficiency of approximately one-watt per c.p., and are generally similar to the 100 and 200-c.p. "One-watt" lamps already on the market, with filaments of wire-drawn tungsten wound on spiders, such as employed in tantalum lamps. They will be supplied with "Goliath" Edison screw caps, and a special brass and porcelain holder has been introduced for use with them. The price at which these lamps are being put on the market compares very favourably with that of other high c.p. metal filament lamps. As in the case of the 100 c.p. and 200 c.p. lamps, they are made for 100–130 and 200–250 volts, and with their robust filaments they should prove of great utility for shop and street lighting. They are, of course, equally suitable for continuous and alternating currents.

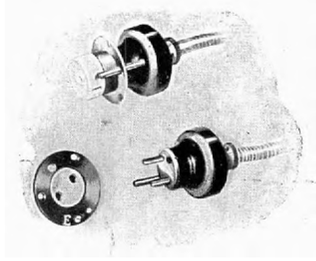
The latest technical development in the lamps sold in this country by G. M. Boddy & Co. (15 Gray's Inn Road) hitherto under the name of the "Metalik" lamp, but now to be known as "Philips" lamps, in view of new arrangements with the manufacturers (Philips Metallic Glow Lamp Works, Ltd., Eindhoven, Holland), is the production of a series of candle lamps, such as are illustrated here. These are made in various bulbs in the 10- and 16-c.p. sizes, for



"PHILIPS" CANDLE LAMPS.
(G. M. Boddy & Co.)

25 to 55 volts, and in the 16-c.p. size for 66 to 135 volts, so that lamps are available by suitable grouping in series where required for the conversion to metal filament lighting of existing two or three light candle fittings on all ordinary supply voltages. Messrs. Boddy are now in a position to offer exceptionally favourable discounts to factors and the trade. The firm were one of the first in the English market with a metal filament lamp, and, in spite of the altered name, it is important to realise that all the time the lamps have been supplied from the same factory, and now represent the result of years of accumulated experience.

Heating and Cooking Apparatus.



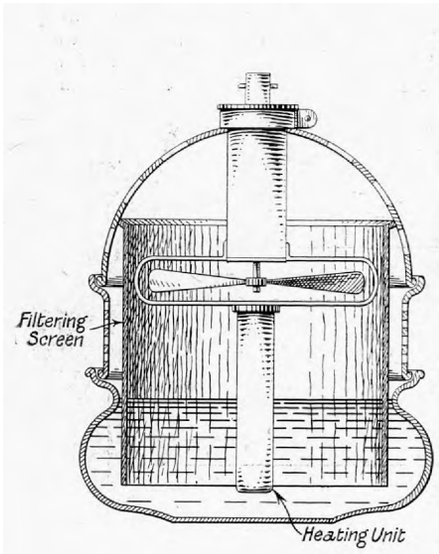
An electrically-heated towel rail is being introduced by Messrs. Purcell & Nobbs (87 Cleveland Street, Fitzroy Square, London, W.), the makers of the well-known "Electroyl" radiators, in which the resistance wire heating elements are immersed in oil. The oil, by being set in a natural state of circulation, ensures a uniform temperature of the whole device and protects the resistance from oxidation. The towel rail consists of three or four horizontal brass tubes of oval section, with or without a double rail at the top connected by two vertical tubes, and provided either with feet for fixture to the floor, as illustrated, or neat brackets for suspension from the wall. The latter arrangement is preferable, as it leaves the floor unencumbered for cleaning. The heating element, which is inserted in the tubes in such a position as to secure a good circulation of the oil, consumes only 150 watts for a 30 in. rail or 250 watts for a 36 in. rail, and maintains the whole at a uniform temperature of from 150 to 180° Fahr., according to the temperature of the room. The running cost of the larger size is thus ¼d. per hour with a 1d. per unit heating rate. The heavily nickel-plated tubes are easy to clean, and have flush joints with no projecting points. An adapter is provided, but, if desired, an indicating switch

"ELECTROYL" TOWEL RAIL.

can be fixed in place of the cord cap. A regulating switch with "full," "medium," or "low" positions, can also be supplied. To ensure that the tubes shall not leak, they are tested to an internal pressure of 50 lbs. per sq. in. Important features of this device are the entire elimination of fire risk and of liability of scorching the towels.

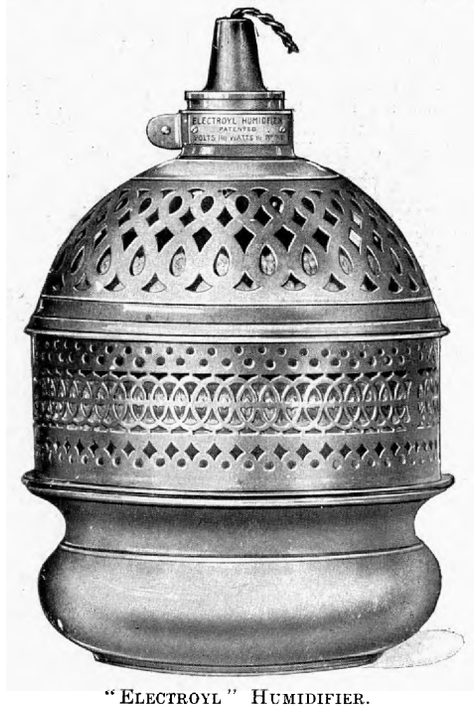
The accompanying illustration shows a new form of plug which the Berry Construction Co., Ltd. (29A Charing Cross Road, W.C.), have introduced for use with their single and extension "Tricity" cookers. Two pins of the plug are for the electrical circuit, and the third is connected permanently to the flexible metallic armouring of the cooker cable, and makes contact with the flange of the socket before the elec-

NEW THREE-PIN WALL PLUG FOR "TRICITY" COOKERS.



trical circuit is completed. An earth terminal is provided on the socket flange, so that insertion of the plug earths the cooker case. A similar socket, but without the earth terminal, is used on the duplex cooker case, so that a single or extension cooker can be connected up without additional wiring. The earth terminal is not necessary in such instance, as the flange of the socket is in metallic contact with the duplex cooker case and earthed through its own cable armouring.

Miscellaneous.



A novel device for improving the condition of air in living rooms, railway carriages, &c., has been introduced by

Hosted by Google

Messrs. Purcell & Nobbs (87 Cleveland Street, Fitzroy Square, London, W.), under the name of the "Electroyl" humidifier. This consists of a small portable apparatus, which sucks in the dry air and expels it through a screen which purifies and moistens it. As can be seen from the accompanying illustrations, the air enters through the perforated dome at the top of the device, and is expelled by a small electric fan through a cylindrical asbestos screen which is partly immersed in the water, perfume or disinfectant liquid, contained in the lower portion of the device. As this screen soaks up the liquid, the air passing through it becomes thoroughly saturated, as well as being filtered and purified. An electric heating unit is suspended in the liquid to increase the rate of production of vapour, and to heat the vapour produced. In the drawing, the device is shown with an adapter connection for suspension from a bracket; larger sizes are made for use in halls and other large buildings. The apparatus is made for all voltages up to 250 volts, and for both D.C. and A.C. circuits. The consumption is about 10 watts only. The dimensions of the size illustrated are 12 in. by 8 in. diam. The apparatus is particularly suitable for use with radiators and other heating devices, as it prevents the air getting into the hot, dry state so detrimental to health.

"ELECTROYL" HUMIDIFIER.

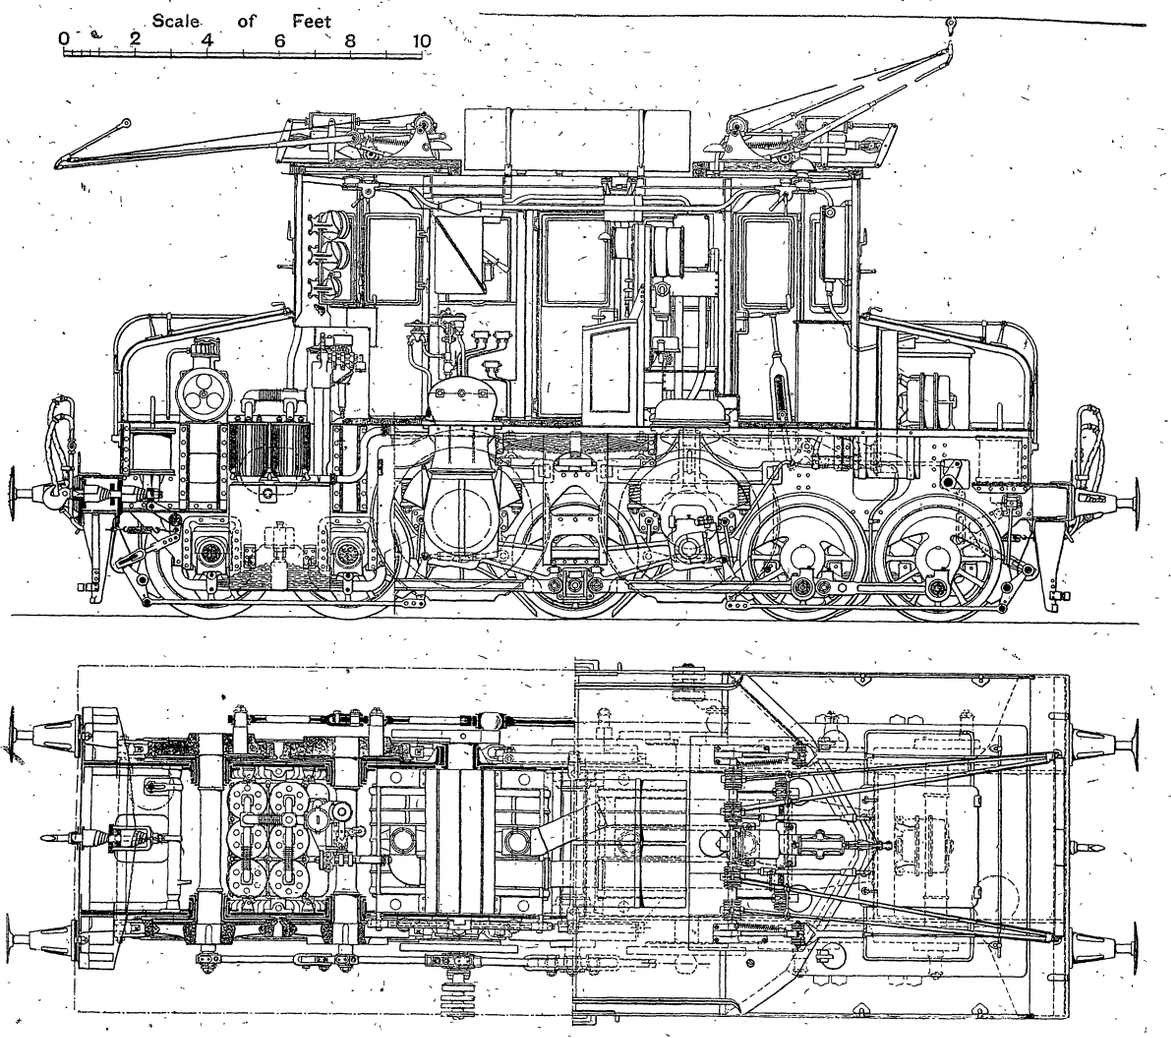
"ELECTROYL" HUMIDIFIER.

Two novelties recently introduced by Simplex Conduits, Ltd., 116 Charing Cross Road, W.C., are illustrated here. One is a self-contained electric motor hair-brush with the motor concealed within the brush. A switch is carried on the handle, and an adapter is fitted for connection to a counterweight pendant lampholder. The other illustration shows an electric vibro-massage set, also intended principally for hairdressers' establishments, where it proves a very remunerative adjunct. A fan for hair-drying can also be fitted to the motor.

"SIMPLEX" ELECTRIC HAIRBRUSH.

"SIMPLEX" VIBRO-MASSAGE OUTFIT.

As we go to press we have received information of a new patent standard ammeter which Messrs. Elliott Bros. (Century Works, Lewisham, S.E.), are introducing. The instrument is constructed on the dynamometer principle with air damping. It can be used on both D.C. and A.C. circuits, and is claimed to be free from wave-form, frequency, and temperature errors. A special three-way switch is provided for enabling the current in the different phases of a three-phase circuit to be quickly determined without opening the secondary circuits of the current transformers. The instrument has a wide open scale, and is particularly suitable for laboratory use. A travelling clip guards the movement from injury in transit, while a front flap protects the glass and scale.



University College.—The introductory lecture by Mr. Archibald R. Low, to his course on "The Design and Calculation of Aeroplanes," was delivered at University College on Friday, Feb 3rd, at 5.30 p.m. Dr. H. S. Hele-Shaw, F.R.S., took the chair.

Telephone Rates.—The Glasgow Corporation have decided to hold a conference in London on the 27th inst., to consider the question of telephone rates, with a view to their revision immediately the Post Office acquires the National Telephone Co.'s undertaking. The Postmaster-General recently stated that this question cannot be considered until the valuation of the National Co.'s property has been considered. It is proposed to ask the Postmaster-General to receive a deputation.

A THREE-PHASE GOODS LOCOMOTIVE

IN an article in the *Zeitschrift des Vereins Deutscher Ingenieure*, Mr. K. von Kando, of the Italian Westinghouse Co., describes a new design of three-phase locomotive, forty of which are now being constructed for use on the electrified main line sections of the Italian State railways. As shown in the accompanying illustration, there are five coupled driving axles, and the two three-phase motors are mounted between the second and third and third and fourth axles. They are 8-pole motors, each rated at 1,000 h.p. on the one-hour rating, and drive through cranks and connecting rods. Two running speeds of 14 and 28 miles per hour, obtained by cascade and parallel connection of the motors respectively, are provided for. The speeds of the motors in the two cases are 112·5 and 225 r.p.m. The driving wheels have a diameter of 3·5 feet. For accelerating, water resistances are used; and the control is effected on the Westinghouse multiple unit pneumatic system, so that two or three locomotives can be simultaneously controlled from the cabin of one of them. The disadvantage of three-phase motors, that equal loading of two or more motors is dependent on exactly equal speeds and therefore equal diameters of the driving wheels, is overcome by an ingenious arrangement whereby the current supplied to the individual motors of two or more locomotives can be regulated at will. Current is returned to the line on down-gradients. Bow collectors, raised and lowered by compressed air, and provided with glycerine dashpots, and similar to those in use on the Valtellina locomotives (see ELECTRICAL ENGINEERING, Vol. I., page 1006), are employed. The total weight of the locomotive, all of which is useful adhesion weight, is 60·2 tons, but this can be increased to 75 tons, if required, by ballast. The total length over the buffers is 31 ft. Current is supplied to the locomotive at 3,000 volts from two overhead lines and the rails. The frequency of the supply is 15 cycles. No transformer is employed on the locomotive, the primaries of the motors being fed direct at 3,000 volts. These locomotives will be used on the Pontedecimo-Busalla section and on the Giovi tunnel section of the main line railways.

2,000-H.P. THREE-PHASE GOODS LOCOMOTIVE FOR THE ITALIAN STATE RAILWAYS.

The Hulton Colliery Disaster.—The following letter has been sent from the Hon. Secretary of the Lancashire branch of the Association of Mining Electrical Engineers to Mr. A. J. Tonge, manager of the Hulton Colliery:—"DEAR SIR,—I have been instructed by my committee to inform you that, at the meeting of our association held at Manchester on Saturday, January 28th, a vote of sympathy with yourself and all who have suffered by the unfortunate disaster which occurred at the Hulton Colliery was passed. May I ask you, on behalf of all who were present at the meeting, to accept the expression of our sympathy?"

Station Lighting on Tube Railways.—In a recent issue we referred to the use of Tantalum lamps for station lighting; and in this connection it is of interest to note that "Onewatt" high c.p. lamps, in conjunction with special holophane fittings, have been approved for use on all stations of the Great Northern and City Railway, to replace the ordinary arc lamps now in use. One of these stations has already been converted, and the others are to be proceeded with immediately. "Tantalum" traction lamps have been used for some time with considerable success in the cars of this railway, and a number of traction companies and corporations are also taking up these lamps for use in their cars.

TRANSFORMER SUB-STATIONS

WE give below a short report of the discussion on Mr. P. V. Hunter's Paper, read before the Newcastle Section of the Institution of Electrical Engineers on January 11th. An abstract of the Paper itself appeared on page 58 of our last issue.

DISCUSSION.

Mr. J. ANDERSON, who opened the discussion, criticised the use of oil-coolers in one of the types of substation described, and thought that as an alternative to the expense of coolers, pipes, pumps, &c., larger transformers were a better way of spending the money. There was also great risk of cooling water leaking into the oil, with disastrous results.

Mr. H. L. RISELY (Newcastle-on-Tyne Electric Supply Co.) pointed out the extreme difficulty in getting at the transformers in some substations, and thought that the more extensive provision of lifting tackle was desirable. He did not like the design of flat roof shown, and agreed with the last speaker regarding the danger of oil leakage.

Mr. A. TURNBULL (Chief Electrical Engineer, North Shields) was much struck with the cost of these elaborate substation arrangements, and questioned whether, after all, the heavy distribution cost did not take away much of the advantage of supply on a large scale.

Mr. FAWSETT spoke of the effec of changes of wind on the efficiency of the ventilating flues, and defended horn arrestors in place of the roller pattern.

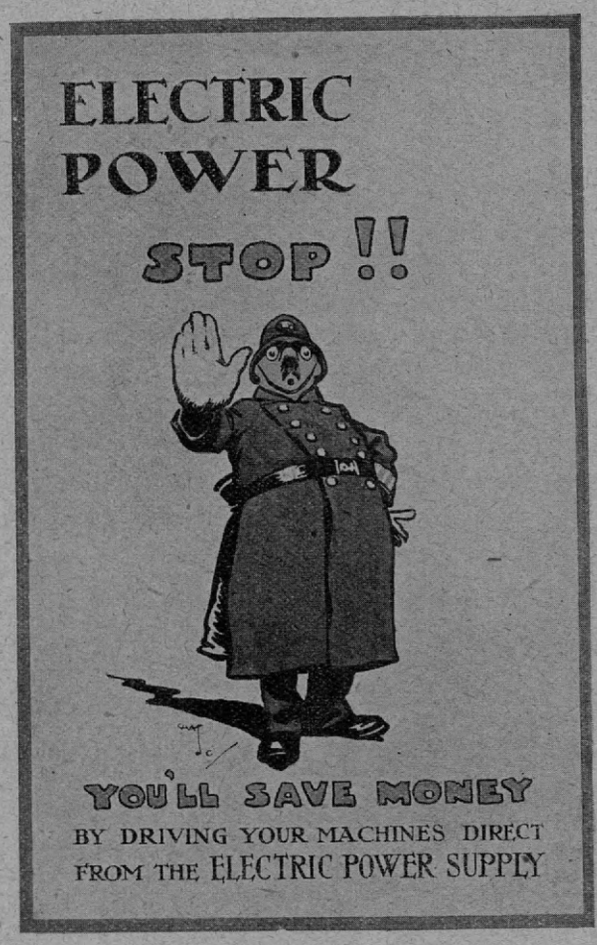
Mr. VERNIER (Newcastle-on-Tyne Electricity Supply Co.) wanted to know how the voltage affected the economical limit of the size of the transformers, and Mr. SHEARER (Newcastle-on-Tyne Electricity Supply Co.) spoke in favour of groups of single-phase transformers instead of three-phase transformers. Mr. HUNT and Mr. PORTER made some further remarks on the nature of the action of horn arrestors.

Mr. H. W. CLOTHIER (Messrs. A. Reyrolle & Co.) looked forward to the time when substation switchgear would be put anywhere, such as in a field, and substation buildings would not exist, and suggested the arrangement of transformer connections so that the whole transformer could be plugged in the same way as is done with his firm's design of switchgear.

After a few remarks by Mr. Wood, Mr. Viall, and Mr. Butcher,

MR. HUNTER said, in reply, that naturally-cooled transformers cost about double the price of water-cooled transformers. He did not think that the danger of water getting into the oil was appreciable. The provision of permanent lifting tackle was, in his opinion, generally a needless expense. Flat roofs were preferable on account of ease of extension. He did not think that the provision of three single-phase transformers with one spare was a sufficient standby, as it would necessitate shutting down to change over. Transformers were not yet available for the open-air service favoured by Mr. Clothier.

CATALOGUES AND PAMPHLETS, &c., RECEIVED



ENGINEERS' STANDARDISED PUBLICATIONS ASSOCIATION.—In view of the desire expressed by some members of this association to have a means of indicating to manufacturers the fact of their membership, the association have prepared a small adhesive label for attachment to correspondence, reading as follows:—"Price lists, leaflets, &c., sent to us through the Engineers' Standardised Publications Association, of Craven House, Kingsway, London, are assured of our notice, and are filed and retained for reference." These may be obtained on application. Among the latest lists, &c., issued by the association are the following:—Leaflet describing the "Flexalite" candle fitting of the Sun Electrical Co. (see ELECTRICAL ENGINEERING, Jan. 12th, page 16); particulars of the new electrically-heated towel rail and humidifier of Messrs. Purcell & Nobbs (see page 70 of this issue); a series of lists of traction specialities, lightning arresters, &c., from Laing Wharton, Ltd., 7 Great Newport Street, W.C., including the V.P. patent link insulator; and particulars of ladders, trucks, &c., supplied by H. C. Slingsby, 142 Old Street, E.C.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

DYNAMOS, MOTORS, &c.—Siemens Brothers' Dynamo Works, Ltd. (Caxton House, Westminster), have issued a list of electrical machines in book form, with convenient thumb index, uniform with the list issued by their supplies department. Full particulars are given of continuous-current, single, two- and three-phase generators, and motors of all sizes and speeds, as well as fans and a very complete range of regulators, starters, and other special switchgear. Spare parts and accessories are also included, and a full series of dimensional outline drawings is given. The whole is wonderfully complete and well arranged, and at the same time conveniently compact.

ELECTRICAL ACCESSORIES FOR MOTOR-CARS, &c.—Messrs. J. C. Fuller & Son (Woodland Works, Wick Lane, Old Ford Road, Bow, E.), have brought out a new catalogue of electrical and automobile accessories, which appears very complete. The ignition appliances include a number of patterns of coils, secondary cells, and accessories, as well as the Fuller magnetos, including their complete dual ignition system. A special feature of the list is the Fuller system of electric car lighting by a small dynamo worked in conjunction with accumulators, and provided with automatic switches to cut the dynamo out of circuit when the speed or the voltage falls. Numerous patterns of side, back, head, and roof lamps are included. The list also deals with charging outfits, primary batteries for all purposes, electric heating and cooking apparatus, and other matters.

SUPPLY ADVERTISING.—The Electric Supply Publicity Committee are continuing their activities in the issue of leaflets. The front of one of the new publications, with a sketch by Mr. C. Crombie, is illustrated here, and the wording is as vigorous and effective as the design. The possibilities opened up by electric radiators are indicated on a new series of postcards and

adhesive labels and a leaflet specially devoted to the use of radiators in bedrooms. Another new illustrated leaflet directs householders' attention to certain aspects of spring cleaning, and in further publications the ways in which electricity can minister to the needs of grocers, florists, drapers, butchers, and hotel-keepers. Several new circulars are directed against gas competition, and other subjects dealt with are "Electric Light and the Eyesight," the cost of wiring, and electric cooking.

"ONE-WATT" LAMPS.—A new price list is being issued by Siemens Brothers Dynamo Works, Ltd., of their "One-watt" lamps, including the new 400-c.p. size, which is described in our article this week on new electrical supplies and accessories. Ten and 16-c.p. lamps for 20 to 50 volts are also included.

SUCTION GAS PLANTS.—The new catalogue dealing with suction gas plants just issued by Crossley Brothers, Ltd. (Openshaw, Manchester), is a fine production, and contains a wealth of illustrations and technical detail concerning the latest forms of suction gas producer plants which are the outcome of the firm's long and extensive experience. Not only are particulars given of the details and the functions explained of each portion of the apparatus, but letters from users are reproduced, from which valuable information as to costs of working and maintenance under actual working conditions can be gathered. An important feature is the special suction producer, which is now available for bituminous fuel and the modification suitable for wood, tan, and other refuse, cotton seed, and other vegetable products. Ammonia recovery plants are also dealt with.

LIBRARY LIGHTING

ON Tuesday, Jan. 31st, the discussion on library lighting, which was commenced on Jan. 16th (see ELECTRICAL ENGINEERING, Jan. 26th, page 45) by the Illuminating Engineering Society, in conjunction with the Library Association, was concluded.

Mr. P. Blagg considered arc lamps too unsteady for general lighting. Difficulties sometimes arose from the impossibility of getting accurate information beforehand as to the arrangement of the furniture, and Mr. V. C. Middleton, as a contractor, agreed, and urged architects and engineers to be more precise in their requirements. In connection with the arrangement of furniture, Mr. J. Duff Brown suggested that in all new buildings the wires should be brought only to the corners of the rooms, and thus give the lighting engineer an opportunity to experiment as to the best positions for the lights. He further suggested the appointment of a committee to draw up a set of conditions which would avoid difficulties of this character.

The lighting of the Patent Office library was again discussed by Mr. V. H. Mackinney (Holophane Co.) and Mr. H. V. Hopwood (Patent Office Library). During the past week or two the Holophane Co. have submitted a scheme for improving the lighting of the alcoves at the Patent Office. Originally the illumination on the tables in these alcoves was from 2 ft.-candles to something under ½ ft.-candle, whilst at the lower end of the bookshelves it was as low as one-third ft.-candle. By a rearrangement of the lamps, the Holophane Co.'s engineers succeeded in improving this to 4 ft.-candles down the centre of the table and 4·4 ft.-candles on the edges. The illumination on the bookshelves had been increased six times. It was found at first that the lamps were too close to the tables, and by the next rearrangement that they were too close to the bookshelves, and that the bottom and least used books were best lighted. The lamps were then lowered a little towards the tables, with the result that they now got about 0·6 ft.-candle at the corners of the bookshelves, which, whilst not bad for the purpose merely of finding a book, was not sufficient for the old bindings in the Patent Office.

The question of indirect lighting was dealt with by Mr. T. F. Ritchie, who mentioned an instance in which the gangways between rows of cases for filing documents were lighted by two 8-ampere inverted arc lamps. The gangways were 6 ft. long by 2 ft. 6 in. wide, and 8 ft. high, and the illumination on the floor in the corners was 2·38 ft.-candles. The illumination on the tables was from 6 to 10 ft.-candles. On the bookshelves the illumination varied only 0·85 ft.-candle over a height of 83 inches from the floor. Mr. Justus Eck was also an advocate of this method of lighting, which he thought was less fatiguing to the eyes.

Another speaker mentioned a room 45 ft. by 30 ft. and 14 ft. high at the Croydon Library that was lighted by metal filament lamps, the light from which was reflected from white ceilings. Several speakers, however, objected to this method of lighting.

There was some difference of opinion on the point of making the general lighting satisfy all requirements, and eliminating local lighting of tables. Mr. Haydn T. Harrison was in favour of local lighting, and mentioned a case which he had in hand where 8-c.p. 25-volt lamps were used upon the tables. Mr. Mackinney suggested that they should aim at getting 10 ft.-candles on the tables and 1/10th ft.-candle for general illumination. Mr. Darch thought that 0·75 ft.-candle was sufficient for general lighting as an average figure.

Some interesting figures were given by Mr. J. H. Quinn of the cost of lighting Chelsea libraries by metal filament lamps, which had superseded arc and Nernst lamps. In 1906 the cost for current was £194, but this has gradually come down, and in 1910 with metal filament lamps the cost was £135, whilst the candle-power had been doubled. Similarly, in 1909, £20 were paid for lamp renewals, whilst in 1910 with metal filament lamps the cost of renewals was only £4 18s. 8d.

THE INSTITUTION DINNER

THE annual dinner of the Institution of Electrical Engineers was held at the Hotel Cecil on Thursday last. Mr. S. Z. de Ferranti, the President, was in the chair, and there was a large attendance, including many distinguished guests. The toast of the evening was proposed by Lord Justice Fletcher Moulton, who referred to the fact that he was a past member of Council of the Institution of Electrical Engineers. The speaker then gave an interesting retrospect of the development of electrical engineering from the time at which, in his last year at Cambridge, he had read the work of Clerk Maxwell with "feverish haste." From being the nerves of the social world, electricity had now become its muscles. The last occasion on which he had had to exercise his judgment on electrical matters was a case in which this delicate electricity had been applied to the brutal work of driving 16,000-h.p. rolling mills. He looked forward to British time being shouted next year from the Eiffel Tower in Paris—unless, indeed, Parliament should by then have passed the marvellous Bill which proclaimed to civilisation that the moral courage of an Englishman is such that he could not get up at six unless he had been told it was seven.

Mr. S. Z. de Ferranti, replying to the toast, said that there were four hundred members present at the dinner as against three hundred last year. Now the Institution was duly installed in its new building, the Council were considering whether it could not be of greater utility to its members. It had been argued that the Institution should be a purely scientific society, but in the Articles of Association the object of the Institution was defined generally as being "to further electrical interests." Members of Council and former Presidents had been afraid of divergent interests, but this was not his view, for the one thing to be considered was the progress and prosperity of the industry. Much good work could be done, and should be done. The present position was not at all satisfactory. We were the nation that first made railways practical, and built railways for the world. We started the great textile industry in this country, and became the textile producers to the world; and as other countries took up textile manufacture themselves, we furnished them with the machinery. In the motor industry we built the first steam road vehicle, which ran from Paddington to the Bank in 1834, but vested interests and other forces had killed this mechanical traction industry; we had to buy millions of material from France whilst unemployed walked our streets. This country had produced the pioneers of electricity. They had had to face a well-established and prosperous gas industry, but this was fair competition, although certainly it meant a disadvantage when compared with countries like America or Switzerland. What they had chiefly to fight against, however, was the "municipal idea" that no one should make a profit out of the industry—that individuals must not make a profit out of the people. This had been largely responsible for electricity not having made the advances in this country which it should have. He did not belittle what we had done, but we should have done much more if we had had a fair chance. There must be a cessation of the idea that no profit or a mere livelihood should be derived from electricity. An impoverished electrical industry meant that no money could be spent on experiments towards improvements, as this could not be done if the industry were starved. He would like to see a competition of excellence rather than a beating down of prices.

Mr. Sam Mavor, Chairman of the Glasgow Local Section of the Institution, proposed the toast of the guests, which was responded to by Mr. Leonard Stokes, President of the Royal Institute of British Architects.

A feature of the evening's entertainment was that there were only four speeches, so that the formal part of the proceedings terminated at about 10.30, and was followed by an informal *réunion* in the adjoining hall, where members could meet their friends and conversation could be carried on uninterruptedly.

Telegraph Traffic and Movements of Cable Ships.—The Indo-European Telegraph Co. succeeded in restoring its lines on the 1st inst., and on the 2nd inst. the El Arich route was restored. The Indo-European lines between Kertch and Soukhoum suffered another derangement on the 5th inst. The *via* Batoum route was restored on that day. New telegraph offices have been opened at Prinzenbucht, in German South West Africa, and at Chinsenda, Elisabethville, Mikola, and Sakania, in the Belgian Congo. The West India system of the Compagnie Française des Cables Télégraphique still gives trouble. The Cape Haiti—Puerto Plata section recently put into working order has again given out, thus cutting off French and Dutch Guianas, Guadeloupe, and Martinique by the *via* Hayti route. Telegrams will be conveyed by special means between the two towns in Hayti unless they are sent *via* Brazil or *via* Key West—Jamaica—Puerto Rico. The c.s. *Mackay Bennett* has again left for Havre, to complete work on the Havre—Waterville cable.—The British Columbia Telephone Co. of Vancouver is about to build a cable ship.

Systems of Wiring.—With reference to the discussion on wiring systems. which was held at a meeting of the Dublin Section of the Institution of Electrical Engineers on Thursday, January 12th (as reported on page 61 of ELECTRICAL ENGINEERING of February 2nd), Messrs. Siemens Brothers & Co., Ltd., point out to us that some of the speakers appear to have been under some misconception regarding the uses to which "Stannos" wires can be put. In the first place, the idea seems to have been in the minds of some of the speakers that "Stannos" wires could only be used in connection with an alternating current supply, and then on the concentric system only; that is to say, with the sheathing forming the earthed return; also that a double-wound transformer is absolutely necessary in such cases. Now, "Stannos" wires are used most extensively on the 2-wire system, in both continuous and alternating current districts, and Messrs. Siemens hold that the suggestion that two wires are unsuitable for an alternating supply, owing to eddy currents being set up in the metallic casings, is quite fallacious. Further, in certain districts where there is an alternating current supply, amongst which Hindhead and Haslemere may be mentioned, the Board of Trade has allowed concentric "Stannos" installations without the interposition of a double-wound transformer.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published February 2nd, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

26,034/09. **Monorail Car.** L. BRENNAN. This specification covers the stability mechanism of the Brennan monorail car described in ELECTRICAL ENGINEERING, Vol. V., 1909, p. 977. The compressed-air gear for accelerating the precession of the gyrostats is described and illustrated. Fifteen figures.

7,574/10. **Determining Position of Faults.** R. A. M. MACALISTER (Greenock). A trolley with a wire brush bearing on the road surface, and connected to one terminal of a voltmeter, is pushed along the road in the path of the cable. The other terminal of the voltmeter is connected to earth at the starting point by means of a wire which is paid out off a reel as the trolley is moved along. Two figures.

9,304/10. **Control of Induction Motors.** H. J. S. HEATHER (Johannesburg). In order to guide the attendant, an ammeter with a mark at the point corresponding to maximum torque at normal voltage is placed in the stator or rotor circuit.

10,370/10. **Ward-Leonard Control.** E. C. MARKS (*Felten and Guilleaume-Lahmeyerwerke A.-G.*). In order to make the variation in speed of the motor exactly proportional to the regulation of the shunt field of the generator and independent of residual magnetism and the C.R. drop in resistances, the generator is compound wound, and its shunt field is controlled automatically by an auxiliary generator coupled to the motor. Five figures.

11,107/10. **Metal Filament Lamps.** O. KRAUSE (Deutsche Gasglühlicht Ges., Auergesellschaft). It has been found that the lamp foot containing the platinum leading-in wires is liable to burst when the binding materials of the tungsten filament are volatilised by raising it to a high temperature. To avoid this, the leading-in wires are temporarily shunted by thicker wires outside the foot, or connection is made above the foot. Two figures.

15,879/10. **Metal Filament Lamps.** K. SCHRÖTER (Berlin). When filaments are drawn from a mixture or alloy of tungsten with a soft metal, the latter is expelled by raising the filament to incandescence after it has been wound on the supports. A deposit of the volatilised metal may be formed on the supports, and, to make its removal easy, these are covered with a film of collodion or wax, which is dissolved afterwards in a solution, and carries the deposit away with it. Two figures.

25,589/10. **Emergency Brakes.** ALLGEMEINE ELEKTRICITÄTS-GES. To open the motor circuit of a locomotive or motor-coach automatically on the application of the emergency air-brake, a contactor in the circuit is forced open against the magnetic pull holding it closed by a piston under air-pressure. A resistance is inserted automatically in the contactor coil circuit to prevent the switch closing on the release of the emergency brake. Three figures.

25,732/10. **Current Transformers.** SIEMENS BROS. & Co., LTD. (*Siemens & Halske A.-G.*). Current transformers consisting of a wound iron ring round E.H.-T. conductors are insulated from them by a series of concentric insulating cylinders of decreasing length. Concentric metal cylinders are placed between the insulating cylinders and are connected to tappings on a transformer or a resistance to equalise the potential gradient. Two figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Dynamos, Motors, and Transformers: POLKEY [Clutch for train-lighting dynamo] 936/10; BURNS [Rotary commutator for obtaining A.-C. impulses from D.-C. supply] 1,475/10; SIEMENS BROS. DYNAMO WORKS and PARKER [Rotary transformer] 4,262/10; SIEMENS BROS. DYNAMO WORKS, KIEFFER and KLOSS [Ventilation of machines] 5,118/10; HILL and TRIER & MARTIN, LTD. [Constant-current dynamo] 5,652/10; ALLGEMEINE ELEKTRICITÄTS-GES. [Cooling of machines] 14,863/10.

Electric Ignition: SCHÜLZKE [Ignition of gas lanterns from a distance] 991/10; KUHN [Sparking-plugs] 27,574/10.

Electrometallurgy and Electrochemistry: HENRI, HELBRONNER and VON RECKLINGHAUSEN [Sterilising of water supply] 2,424/10; THOMPSON (*Mix & Genest Telephon und Telegraphenwerke*] [Process for pickling aluminium and its alloys prior to coating] 13,012/10.

Incandescent Lamps: BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Treatment of tungsten to facilitate working] 23,499/09.

Storage Batteries: NAYLOR [Process for regenerating plates] 1,558/10; HAZLEHURST and LONGSTRETHS, LTD [Method of determining when battery is fully charged] 1,677/10.

Switchgear, Fuses, and Fittings: ESKRIGGE [Attachment of shades and reflectors to lamp-holders] 415/10; EVANS [Lamp-holders, ceiling-roses, &c.] 1,164/10; LUCAS [Electro-magnetic relays] 1,167/10; DEWSE and DEWSE [Shade-carrier for lamp-holders] 1,465/10; WHITE [Control of electrically-operated switches] 4,811/10; PARKES [Bells] 5,014/10; PIZZUTI and FERRARI [Safety apparatus for discharge of high potentials] 6,865/10; HIRST and RECORD [Automatic control gear] 10,530/10; TRIN [Safety lamp] 12,368/10; SIEMENS BROS. & Co., and IRELAND [Elbow joints for wiring conduit] 20,427/10; DICKS [Seamless conduit] 32/11.

Telephony and Telegraphy: MARKS (*Electro-mechanical Works*) [Telephone switch apparatus] 1,281/10; DICKER (*Automatic Electric Co.*) [Telephony] 1,298/10; MELLINGER [Telephony] 1,418/10; MARTIN [Telephony] 1,419/10; SIEMENS BROS. & Co. and RIBER [Telephone receivers] 1,598/10; STERLING TELEPHONE & ELECTRIC Co. and BELL [Intercommunication telephone systems] 1,631/10; BETULANDER [Automatic telephone exchanges] 1,946/10; GOLDSTEIN and POOL [Central energy signalling system] 16,334/10; EISENSTEIN [Oscillation generator for wireless telegraphy] 16,371/10; CARPENTIER [Perforated tape telegraphic transmitter] 19,102/10; DICKER (*Automatic Electric Co.*) [Telephone receiver] 29,182/10.

Traction: PIEPER [Vehicle propulsion and control] 1,434/10; PECKHAM and ANDREWS [Railway and tramway trucks] 1,850/10; JONES [Entrance devices for tramcars] 3,717/10; JACKSON and FOURNISS [Current Collectors] 5,098/10; RAVEN [Signalling] 6,859/10; GAUNT [Permanent way] 11,815/10; BATTAILLE [Operating points and switches] 19,619/10.

Miscellaneous: BRANDENBURG [Automatic electrically-driven pumps for domestic water supply] 29,383/09; COWPER-COLES [Non-dazzling lamps] 1,101/10; MURDAY and REASON MANUFACTURING Co. [Electric clocks] 1,326/10; MAVOR & COULSON, LTD., and DEMPSTER [Coal-cutters] 1,383/10; BIGGE and BUTT [Mercury breaks and interrupters] 3,209/10; SCHWARZSCHILD [Electrically-driven cutting-out machine] 5,900/10; NEILL [Electric clocks] 11,379/10; ELIA [Submarine mines] 14,511/10; MYERS [X-ray shield] 17,782/10; SIEMENS BROS. & Co. [*Siemens & Halske A.-G.*) [Electro-medical electrode holders] 21,389/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: FRIED. KRUPP. A.-G., 25,167/10.
Electric Ignition: SAUERBREY [Distributer] 790/11.
Heating: TRÜMPLER [Regulating apparatus] 30,201/10.
Traction: CAMPANA [Automatic switch] 1,020/11.
Miscellaneous: SIEMENS SCHUCKERTWERKE GES. [Percussion tools] 19,540/10; LINDER [Ozonisers] 447/11.

The following amended Specifications can now be obtained.

G. BELLUZZO [Steam turbines] 2,215/09; G. OKILL [Storage battery plates] 8,875/09; STOTHERT & PITT and W. PITT [Electric cranes] 14,318/09.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

4,120 of Feb. 16th, 1897. **Electrolytic Apparatus.** W. HALL. Metal articles, such as pins, tubes, handles, &c., are tapered by being drawn through an electrolytic bath of which they form the anode. The articles are rotated to preserve a uniform section, and the shape is determined by their rate of axial movement or by the current density.

The following are the more important Patents that have become void through non-payment of renewal fees.

Dynamos, &c.: BRITISH THOMSON-HOUSTON Co. (*W. S. Moody, U.S.A.*) [Air-cooled H.-T. transformers] 24,129/97; K. A. LINDSTRÖM [Elimination of harmonics in alternator E.M.F. waves] 21,889/04; SIEMENS BROS. & Co. (*Siemens-Schuckertwerke Ges.*) [Improving commutation of A.-C. and D.-C. commutator motors] 22,653/04; A.-G. BROWN, BOVERI & Co. [Stators of A.-C. repulsion motors] 20,772/05.

Electrometallurgy, &c.: S. O. COWPER-COLES [Rotation of cathode in baths for electrodeposition of metals] 21,974/98; C. N. RÜBER [Electrolysis] 20,898/05.

Incandescent Lamps: V. I. FEENY (*Allgemeine Elektricitäts-Ges.*) [Resistance for Nernst and other lamps consisting of iron wire in bulb of hydrogen] 20,720/99.

Switchgear, &c.: R. H. KNIGHT and L. NAGEL [Wiring conduit] 21,071/05.

Telephony, &c.: H. T. CEDERGREN [Central battery telephone system] 6,484/02.

Traction: E. PECKHAM [Axle-trucks and brake-rigging for railway and tramway vehicles] 23,907–8/97; W. C. KIRWAN and K. QUANEY [Prevention of falling of trolley-wires broken at the ears] 22,404/04; SIEMENS BROS. & Co. and F. LYDALL [Multiple-unit control system with single-phase motors] 21,068/05.

Miscellaneous: G. B. BOWELL and PEARSON FIRE ALARM, LTD. [Fire alarm system] 22,456/03.

THE MANCHESTER ELECTRICITY AND GAS DEPARTMENTS

AS we have pointed out in recent issues, the question of the relative sums which the Manchester Corporation Electricity and Gas Departments should pay towards the relief of rates is under consideration, and the views of the Electricity Committee regarding this will soon be made public. The dispute, if it can be called such, arises out of a discussion which has been developing for some time past as to what extent there should be competition between two municipal departments supplying power. In some quarters the opinion has been expressed that a Joint Committee should be formed to deal with all applications for power supply and lighting, whether electricity or gas, and that there should not be active competition between the two. It appears probable that this policy may be adopted in the case of new districts which are developed from time to time. This, however, may be a matter for the future; the present controversy is to settle a common basis upon which contributions in aid of rates should be made out of profits. It has been claimed that the Electricity Committee does not contribute to the relief of rates to the same extent as the Gas Committee, but, so far as public discussion has gone at present, the real point seems to have been missed. A simple inquiry will show that the Gas Committee, by reason of it having been established many years longer than the Electricity Committee, has to pay interest on nearly £1,000,000 less capital than does the latter, as a large proportion of the early capital expenditure has been already repaid by the usual statutory allocations to sinking fund out of past revenue. The Gas Committee have repaid £1,678,721 out of a total of £2,851,184, whereas of the capital expenditure upon the electricity undertaking, viz., £2,678,629, only £677,199 have been repaid. It has been calculated that the Gas Department pays £27,297 less in interest charges than the Electricity Department. If allowance is made for this, the percentage of rate aid to capital of both departments will not show that startling difference which appears to be agitating the minds of some of the Manchester councillors, and the local and municipal Press. Of considerable importance, too, is the fact that the Electricity Committee supply the Tramways Committee with energy at cost price, without taking any profit, and the capital invested for this purpose is approximately £1,000,000.

We think it will be found to be a somewhat striking fact that whereas the charge has been made that the Electricity Committee are unduly cutting prices, the officials of the two committees are agreed that the charges made by the two departments have been fixed on recognised principles, and that no arbitrary ruling can be laid down. This being so, it may yet be necessary for some of the participants in the controversy to modify their views.

LOCAL NOTES

Dawlish: *Street Lighting.*—The local Electric Light Co. have offered to install 250-c.p. lamps, and maintain them, the Council merely paying a charge of 3d. per unit for current consumed. The offer has been referred to the Lighting Committee.

Dublin: *Heavy Tramway Damages.*—A verdict of £800 was given against the Dublin United Tramways Co. last week in an action brought by Mr. E. N. Richardson for damages through a horse which he was driving stumbling on the tram lines and throwing him out of a trap, fracturing his collar-bone. It was alleged that the tram line where the accident occurred was in a defective condition.

Electricity Extensions.—The Electricity Committee, as announced in our last issue, recommend the Council to apply to the Local Government Board for a loan of £128,129 for further extensions to the electricity undertaking. The progress of the electricity department was, the committee say, brought almost to a standstill by the introduction of metal filament lamps, which inquiries made by the electricity officials show were more rapidly availed of in Dublin than in almost any other city, but the stoppage of the progress was more quickly got over than elsewhere. Mr. Ruddle, the City Electrical Engineer, estimates that the demand for next winter can be met by an additional expenditure of £55,000, the greater proportion (£33,000) of that sum being on a further installation of plant at the Pigeon House station, which is immediately necessary. As a safeguard, the committee consider that any application made to the Board should cover the probable capital requirements for the next three years, and these requirements are estimated to work out as follows:—Expenditure (already incurred) in excess of amount applied for in 1909 on short extensions, house services, motors, &c., £10,129; extensions of plant in 1911, £40,000; new high-pressure feeder mains from Pigeon House to Fleet Street (1912), £9,000; short extensions, house services, and alterations to distribution system (1911), £15,000; ditto (1912), £15,000; ditto (1913), £15,000; second additional set of plant probably required by 1912, £24,000; total, £128,129.

Dundee: *Tramway Policy.*—A deputation from the Tramway Passengers' Association waited upon the Council last week in regard to certain matters relating to the management of the tramway system. They complained of the tramway department being charged a higher rate for energy than is being charged to private consumers using far less current. They also took exception to £250 per annum being paid by the Tramways Department towards the City Engineer's salary, and £150 per annum towards the City Treasurer's salary.

London: *Holborn: Street Lighting.*—A most extraordinary report has been presented by the Highways Committee with regard to street lighting. The competition in Gower Street between gas and electricity resulted in a considerable margin in favour of the latter, and, based upon these figures, the tender for electric lighting for 405,000 c.p., the lamps varying from 60 c.p. upwards, amounts to £6,688 per annum, against £7,527 for gas. Nevertheless, the Council are recommended to give the contract to the Gas Co., on the ground that it is inadvisable to have two systems of street lighting, and that to adopt electricity would involve considerable interference with the roads in laying mains and making the necessary connections. We shall deal fully with the matter in our next issue.

County Council: Tramways.—The Highways Committee again report in favour of removing the disused horse tram lines in Liverpool Road, Islington. The Islington Council is very much opposed to this course.

Manchester: *Tramwaymen's Agitation.*—The dispute between the Tramways Committee and their employers still continues, and at a meeting on Sunday the men agreed to accept arbitration on condition that no reduction in wages is contemplated in conjunction with the reduction of hours asked for.

Motherwell: *Action against Tramways Co.*—An action for £1,000 damages for personal injuries against the Lanarkshire Tramways Co., which was commenced last year by Joseph M'Pherson, a Motherwell miner, has been abandoned.

Newcastle: *Tramway Extension.*—A request has been made for a poll of ratepayers, in view of the opposition to the Corporation's proposed tramway extension to Newburn, and the running of trolley omnibuses.

Stourport: *Electric Lighting.*—The Kidderminster & Stourport Electric Tramways Co. have possessed an electric lighting Provisional Order for several years, but as they have not made any commencement with the works, the Board of Trade propose to revoke it. Before doing so, however, they have asked for any observations from the Council.

Torquay: *Tramways.*—The Torquay Tramways Co. have raised the necessary £60,000 for extending the tramways to Paignton, and converting the system in Torquay to overhead trolley. The extension to Paignton, which at one time it was feared would have to be abandoned, is likely to be in operation in a very few months.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Aberdeen.—The recommendation of the Electrical Engineer to instal a 1,000 kw. direct-current dynamo, condenser plant, &c., at an estimated cost of £7,285, has been adopted, The details are as follows: 1,000 kw. high-pressure turbine, D.-C. dynamo, and condenser, £5,450; sub-station building at Culter, £438; one 50 kw. three-phase transformer, £95; E.H.T. switchboard panels, £200; laying E.H.T. cables, Murtle to West Cults, £265; one 65 B.H.P. three-phase motor, complete for coupling to existing dynamo, £175; and contingencies, £662.

Australia.—Tenders are invited by April 4th by the Deputy Postmaster-General, Melbourne, for the supply of 10¾ miles

Hosted by Google

of lead-covered paper insulated telephone cable. Specifications, &c., at 72 Victoria Street, and 73 Basingnall Street, London.

Bedford.—Application is to be made for a loan of £22,837 for electrical extensions.

Belfast.—The Tramways and Electricity Committee invite tenders for twelve months' supply of V.B. cable. (See an advertisement on another page.)

Coventry.—A loan of £9,713 for extensions at the Electricity Works is to be applied for.

Dublin.—Tenders are invited for a turbo-alternator and other plant. (See an advertisement on another page.)

Gloucester.—Tenders are invited for a 750-kw. D.C. turbo-generator with surface condensing plant, a 150-kw. motor-generator; also switchgear. Particulars from the Town Clerk, and tenders by February 21st.

Heywood.—A Local Government Board inquiry was held last week concerning a loan of £4,355 for electrical extensions.

London: *Hackney.*—Mains are to be laid to Messrs. Gibson Bros.' premises, Andrew's Road, at an estimated cost of £77 10s.

St. Pancras.—The Finance Committee of the L.C.C. recommend sanction to a loan of £2,582 for electrical extensions.

Reigate.—Messrs. Handcock & Dykes are preparing specifications for two 100 kw. Diesel engine alternator sets at the Corporation power station.

St. Helens.—An additional 1,500 kw. turbo-generator, boiler, and coal-conveying plant is to be installed at an estimated cost of about £10,800.

Sale.—A new switchboard and crane are required at the generating station. Particulars from Mr. C. Hopkinson, 29 Princess Street, Manchester.

Wolverhampton.—Extensions are to be made to the power station at Messrs. Bayliss, Jones & Bayliss's works.

Worthing.—Additional generating plant is to be put down at an estimated cost of £4,500, and an accumulator at an estimated cost of £2,940. Schemes for the erection of steam plant and Diesel engines have been prepared by the Borough Electrical Engineer, and the committee recommend the Council to obtain the opinion of an outside electrical engineer.

York.—The City Electrical Engineer recommends the installation of a 1,000 kw. turbo-alternator, a water-tube boiler, pumps, transformers, switches, &c., at an estimated cost of £9,600, and mains and extensions at an estimated cost of £5,400. A loan of £15,000 is to be applied for.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

GREATER LONDON.

Sanatorium for Consumptives at West Ham. Board of Guardians.

Twelve houses in Bingham Road, Croydon. R. Palmer, Sherwood Road.—130 houses in Dalmeny Avenue. A. Gosheron, 1 Tennison Road, Croydon.

PROVINCES.

Cardiff.—Block of houses, Spring Gardens Terrace. City Engineer.

Derby.—New County Offices, St. Mary's Gate.

Gloucester.—New Drill Hall and other buildings for Territorial Force Association. Architect, J. Craik, 12 Stevens Street, Bristol.

Hamilton.—Infants' School in Beckford Street.

Manchester.—Shakespearian Theatre and Grand Opera House, Deansgate. Architect, C. Twain, Exchange Street.

Paisley.—New offices and machine shops at Messrs. Fullerton, Hodgart & Barclay's works, Renfrew Road.

Renfrew.—New soap works. Messrs. Ogston & Tennant.

Salford.—New office accommodation for Guardians.

Stockport.—New police buildings in Fletcher Street.

Stockton-on-Tees.—New boys', girls', and juniors' blocks at Yarm Road Schools.

Stoke-on-Trent.—The Education Committee have been requested to consider the advisability of lighting all the schools under their control in Hanley and Tunstall with electricity.

Swansea.—A new theatre, also electric theatre in Oxford Street.

Weymouth.—Enlargement of Sailors' Home.

Wolverhampton.—Extensions to Royal Orphanage, Penn Road.

MISCELLANEOUS

Belfast.—The Tramways and Electricity Committee invite tenders for twelve months' supply of stores. (See an advertisement on another page.)

Bexley.—The question of spending £1,000 in order to fit new brakes to the tramcars is under discussion.

Burnley.—Alterations to the tramway track are to be carried out at an estimated cost of £800.

Grimsby.—A supply of continuous-current motors and starting panels is required. (See an advertisement on another page.)

Leeds.—Tenders are invited for a twelve months' supply of stores, including electric light fittings. Particulars from the Town Clerk.

The Tramways Committee invite tenders for points and crossings, rails, fishplates, tie-bars, and reconstruction of certain portions of tramway track, copper bonds, &c. Particulars from the Town Clerk, and tenders by February 16th.

London: *Bermondsey.*—Arc lamp carbons, brushes, cable, jointing material, and other electrical supplies are required by the Electricity Committee. Particulars from Town Clerk, and tenders by February 20th.

TENDERS RECEIVED AND ACCEPTED

Aberdeen.—The tender of the British Insulated & Helsby Cables, Ltd., for a twelve months' supply of cable has been accepted.

Bedford.—The tender of the British Thomson-Houston Co., Ltd., has been accepted for the supply of electricity meters during 1911.

Buckingham.—The tender of Messrs. Johnson & Phillips, Ltd., has been accepted for an electric lighting plant at the workhouse at £180.

Colne.—The tender of the United Electric Car Co., Ltd., has been accepted for four sets of tramcar brakes.

Stoke-on-Trent.—The following tenders have been accepted: D.-C. meters, Electrical Co., Ltd.; boosters, Electric Construction Co., Ltd.; portable current transformers, Weston Electrical Instrument Co.; portable sub-standard ammeter and wattmeter, Siemens Bros. & Co., Ltd.; volt meter switches, Crompton & Co., Ltd.; multiple way switches, Spagnoletti, Ltd.; cotton-covered wire, London Electric Wire Co. and Smith's, Ltd.

APPOINTMENTS AND PERSONAL NOTES

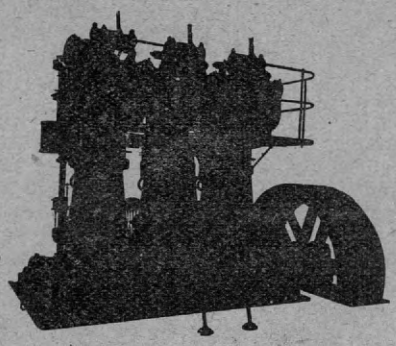
Mr. Newcomb Carlton, who has retired from the position of Managing Director of the British Westinghouse Electric and Manufacturing Co., Ltd., is taking up the position of Vice-President of the Western Union Telegraph Co. in New York.

Mr. Herbert Taylor, shift engineer at Accrington Electricity Works, has resigned.

Mr. W. G. Ritchie, assistant engineer to the Mexborough & Swinton Tramways Co., has been appointed manager to a tramway company in Nova Scotia. He sailed for Canada last week.

A switchboard attendant is required at Newport. (See an advertisement on another page.)

A. Southby has been appointed electrical assistant in the Chief Engineer's Department of the L.C.C. at 47s. 6d. a week, rising to 50s. a week.



Wireless Telegraph Notes.—We are informed that the India Office has concluded a contract with Marconi's Wireless Telegraph Co., for the erection of wireless telegraph stations at Calcutta, Delhi, Allahabad, and Simla. These stations will be used primarily for military and Government purposes. In the case of the first three stations, the range will be 600 miles, whilst that at Simla will have a range of 300 miles. The total cost of the stations, which it is hoped to have in working order in time for the Durbar in 1912, will be about £50,000.

It is stated that a new English company is to be formed to exploit the Poulsen wireless telegraph and telephone systems. Successful experiments have been carried out recently between Copenhagen and Ireland, and it is said that the company hope to complete a station in Canada within a year, and then start a regular wireless transatlantic wireless service.

Herr Goldschmidt, of the Darmstadt Technische Hochschule, has developed a system of wireless telegraphy, using an extra high-frequency alternator to produce the oscillations. Satisfactory results are reported, but as yet no technical particulars are to hand.

MISCELLANEOUS BUSINESS NOTES

The British Prometheus Co.—This company announce that Simplex Conduits, Ltd., are no longer agents for their specialities, and request that all orders and inquiries be sent either to their works (Salop Street, Highgate, Birmingham) or to their London showrooms (9 Newman Street, Oxford Street, W.). In view of apparatus of similar appearance on the market they remind their clients that all apparatus of their manufacture bears their diamond-shaped trade mark, with the word "Prometheus" in the centre and "British manufacture" below.

Silvertown Company's Dinner.—On Saturday, January 28th, the staff of the India Rubber, Gutta Percha, & Telegraphs Works Co., Ltd., of Silvertown, held their 28th annual dinner and social evening, and a very enjoyable evening was spent. Mr. W. E. Gray was in the chair.

Change of Address.—The Empire Roller Bearings Co., Ltd., have removed from No. 15 to more commodious premises, at No. 17 Victoria Street, Westminster, S.W.

Agency.—The Electric and Ordnance Accessories Co., Ltd., have appointed Mr. F. MacCallum (late of J. P. Hall & Co., Oldham) to represent them exclusively in Yorkshire. Mr. J. Booker will confine himself to the Lancashire district.

Osram Lamps.—The Chief Engineer of the Madeira Electric Lighting undertaking has informed the General Electric Co., of London, that a number of 32-watt, 230-volt Osram lamps used for street lighting on a D.C. system on which the pressure varies as much as 10 volts or more during the evening, have given every satisfaction, many having burned for as long as from 3,500 to 4,300 hours, in spite of being subject to much vibration.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

St. James' & Pall Mall Electric Light Co.—The net profits for the year 1910 amounted to £27,090, in addition to £2,025 carried forward. After meeting the 7 per cent. preference dividend, a dividend at the rate of 10 per cent. per annum is recommended on the ordinary shares, carrying forward £2,116. The total connections now amount to 12,999 kw., an increase of 1,134 kw. over the previous year. The main boiler plant at the Carnaby Street Works has been fitted with furnaces for the consumption of bituminous coal, and the Mason's Yard Works are being equipped as a high-tension transformer station.

Central Electric Supply Co.—The report for 1910 shows that 18,641,190 units have been supplied to the Westminster and St. James' Companies, and that, after making allowance for sinking fund and depreciation, the net profit is £4,991, in addition to £36 brought forward. A 5 per cent. dividend is declared.

London Electric Railways Co.—This report represents the combined figures of the Great Northern, Piccadilly & Brompton, Baker Street & Waterloo, and the Charing Cross, Euston & Hampstead Railways for the December half-year. The gross receipts show an increase of £6,837 over those of the previous corresponding half-year, whilst working expenses decreased by £4,106. The net sum available is £101,454, and after meeting the 4 per cent. preference dividend, a dividend at the rate of ¾ per cent. per annum is declared upon the ordinary shares.

Chelsea Electricity Supply Co.—Dividend at the rate of 6 per cent. per annum for the December half-year, making 5 per cent. for the year, placing £12,772 to depreciation, £704 to debenture premium redemption fund, writing off £1,089 from cost of extinction of founders' shares, and carrying forward £2,290.

Central London Railway Co.—At the meeting last week, Sir Henry Oakley, chairman of the company, said that the work upon the Liverpool Street extension was going on satisfactorily although somewhat slowly, owing to the fact that the whole of the work, including the station, will be underground. The question had been raised by several shareholders as to the position of passengers if a breakdown occurred on the line. In consequence the Board had considered this matter with their engineers, and arrangements had been made by which, in the event of failure at their power station, each carriage will be separately lighted, and passengers will be able to walk along the track to the next station. Provision had also been made for the lifts to be moved up and down by hand power. At the new Liverpool Street station a movable staircase was to be constructed.

Westminster Electric Supply Co.—Dividend at the rate of 10 per cent. per annum for the December half-year.

Yorkshire Electric Power Co.—The net profit for 1910 amounted to £6,503, compared with £2,665 in the previous year. The full dividend on the 6 per cent. cumulative preference shares is recommended, carrying forward £9,450, which includes £3,382 brought forward from 1909.

South London Electric Supply Corporation.—Dividend of 5 per cent. on the ordinary shares for 1910.

Brighton, Hove & Preston Omnibus Co.—At the annual meeting last week reference was made to the company's Bill in Parliament for running trolley omnibuses between Brighton and Worthing. The directors have been watching the developments in this method of traction with a view to its ultimate adoption, but their hand has been forced somewhat by the promotion of a Bill by the British Electric Traction Co. to run tramways between these places. The Tramway Company's Bill having been deposited, the directors of the Omnibus Company felt they had no alternative but to oppose it with a scheme of their own which they regard as more suitable to residential districts of this character than tramways.

TENDERS INVITED.

CORPORATION OF DUBLIN.

Tenders for Electrical Plant.

The Electricity Supply Committee of the Corporation of Dublin desire to receive Tenders for the supply and installation at their Pigeon House Generating Station, of a complete GENERATING SET of approximately 3,000 Kw. capacity.

This set to form a complete unit comprising STEAM-TURBO ALTERNATOR and EXCITER, CONDENSING PLANT, the necessary WATER-TUBE BOILERS, STOKERS, STEEL CHIMNEY with INDUCED DRAFT FANS, FEED PUMPS, CIRCULATING PUMPS, STEAM and WATER PIPING, FOUNDATIONS and BUILDINGS.

As the entire plant must be completed for beneficial use by October 31st next, it is necessary that intending Tenderers should at once inspect the site in order that they may be fully informed of the conditions to be complied with as to space and local requirements, and no tender will be considered which is not based upon such inspection.

General Conditions, Specification, and Form of Tender may be obtained from the City Electrical Engineer, Fleet Street, Dublin, on and after Tuesday, February 14th, 1911, on payment of three guineas, which sum will be refunded on receipt of a *bona-fide* tender.

Tenders, sealed and endorsed "Tender for complete 3,000 kw. Steam-Turbo Generating Plant," must be addressed to "The Chairman, Electricity Supply Committee, 3 Cork Hill, Dublin," and delivered there not later than 12 o'clock noon on Monday, March 6th, 1911.

The Committee do not bind themselves to accept the lowest or any Tender.

FRED. J. ALLAN,
Secretary.

SUMMARY

A Special Literary Supplement is included in this issue, containing notices and reviews of books, and a carefully revised list of selected works on electrical engineering and allied subjects.

The two Papers on high-tension transmission lines by W. T. Taylor and by R. B. Matthews and C. T. Wilkinson, respectively, were further discussed at the Institution of Electrical Engineers on Thursday last. Mr. S. G. Redman described the practice adopted for the north-east coast 20,000-volt lines. Mr. Trotter, speaking with regard to progress in this country, thought that 20,000 volts would be the highest that would be required. A new pattern of lightning arrester was described by Mr. J. S. Peck. Mr. Clothier referred to the use of the balanced system of protection on long-distance lines, and Mr. W. B. Esson, Mr. A. A. Campbell Swinton, Dr. M. Kloss, and Mr. B. M. Jenkin also spoke. A full report will be published in a future issue.

At a meeting of the Holborn Borough Council on Wednesday last week a report of the Works Committee to accept the tender of the Gas Light & Coke Co. for street lighting at a price per annum nearly £1,000 higher than the tender for electric lighting was referred back, with instructions to the Committee to bring up a fresh report within one month. (Page 81.)

The special committee appointed to inquire into the working of the special rules for the use of electricity in mines have issued their report, together with a suggested revised code of rules. The prohibition of the use of electricity where gas is continuously present is recommended, and it is suggested that the rules should apply to metalliferous mines also. (Page 82.)

The first meeting of the Advisory Committee of the Electrical Exhibition, which is to be held next September at Olympia, took place last week, when a number of schemes for adding to the utility of the Exhibition were considered. (Page 82.)

A new automatic voltage regulator has been designed by Messrs. H. M. Taylor and R. W. Scotson, of the Middlesbrough Electricity Department, in which a solenoid switch controls the excitation of a booster in the exciter field circuit of the main alternators. (Page 83.)

Among the specifications published by the Patent Office on Thursday last was one by the British Thomson-Houston Co. for a process for the manufacture of drawn tungsten filaments. Two patents cover devices for attaching shades to lamp-holders. E. H. Naylor describes a method of improving and renovating storage-battery plates. As the result of opposition, a patent by J. Neu for a supported-carbon arc-lamp with a pivotted stop has been surrendered. (Page 84.)

The Chelsea Borough Council have renewed a contract for street lighting with gas, although the electricity company quoted a lower price.—The Leicester Corporation are selling off their stock of electric fittings, in consequence of the recent decision of the Courts.—Bethnal Green Council seem unable to come to a decision with regard to electric supply.—A number of 1,000-c.p. metal-filament lamps are being used at Torquay for street lighting.—Newport Electricity Committee recommend an expenditure of £2,000 upon a Sales Department.—The Manchester Tramways Committee refuse to accept arbitration with regard to the men's conditions, unless the question of wages is also considered.—An offer by a private firm to run the Dover Electricity and Tramways Departments has been rejected. (Page 85.)

Hosted by Google

Two water-cooling towers are required at Edinburgh; a 500-kw. rotary converter at Govan; a 300-kw. motor generator set at Brighton; and water-tube boilers, superheaters, &c., at Hammersmith.—Loans of £9,000 and £6,000 are required at Gravesend and Rathmines respectively.—Overhead tramway-line material is required at Brighton.—An electric lighting scheme is under consideration at Uttoxeter, and electrical stores are required by the Marylebone Council. (Page 85.)

ALTHOUGH the net revenue on the London United Tramways Co. for 1910 increased by £7,788, no dividend is declared upon the ordinary shares.—The accounts for Messrs. Bruce Peebles & Co., Ltd., for 1910 show a loss of £7,275.—Messrs. Mather & Platt, Ltd., declare a dividend of 10 per cent. and a bonus of 2 per cent. on the ordinary shares. (Page 86.)

Yorkshire Section of the Institution of Electrical Engineers.—The annual dinner of this Section was held at Leeds on Friday last, under the chairmanship of Mr. T. Harding Churton, the number present being over one hundred. In proposing the toast of the City of Leeds, Mr. Robert Hammond referred to the excellent results obtained by the electricity and tramways undertakings under the management of Mr. H. Dickinson, and, in replying to this toast, the Lord Mayor, Mr. W. Middlebrook, spoke of the diminution of fog consequent upon the more extended use of electricity. The toast of the Institution was proposed by Ald. C. F. Tetley, and responded to by Mr. S. Z. de Ferranti, President, who prophesied an enormous increase in the consumption of electricity.

Telegraph Traffic.—During the past week the El Arich route was down between Adana and Beyreuth, and also between Alep and Beyreuth. A stoppage also occurred in communication between Ceiba and Trujillo in Honduras on the 9th inst. —The *via* Hanekin route was deranged on the same date between Konia and Adana, and the *via* Batoum route between Samsoun and Trebizoude.—The lines of the Indo-European Telegraph Co. were repaired on the 9th, and the Hong Kong-Macao cable failed on that day, but was restored on the 11th inst.—The New York-Haiti Cable Co. was successful in restoring their Cape Haiti-Puerto Plata section on the 13th inst.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, FEBRUARY 16TH.

Illuminating Engineering Society.

8 p.m. At Royal Society of Arts. Discussion on "School Lighting," to be opened by Dr. James Kerr, Medical Officer to the L.C.C., and Dr. N. Bishop Harman.

FRIDAY, FEBRUARY 17TH.

Institution of Mechanical Engineers.

8 p.m. At Storey's Gate, Westminster. Adjourned discussion on "Modern Electrical Dock Equipment, with special reference to Electrically-operated Coal Hoists," by W. Dixon and G. H. Baxter.

Institution of Electrical Engineers: Newcastle Section.

Annual dinner at Tilley's.

Institution of Civil Engineers.

8 p.m. At Great George Street, Westminster. Lecture I., on "The Uses of Chemistry in Engineering," by James Swinburne, F.R.S.

Tramways and Light Railways Association.

7 p.m. Annual meeting at Gaiety Restaurant, Strand, to be followed by annual dinner and smoking concert.

SATURDAY, FEBRUARY 18TH.

Birmingham and District Electric Club.

6.30 p.m. Annual dinner at Colonnade Hotel, New Street.

Institution of Electrical Engineers: Students' Section.

7 for 7.30 p.m. Dinner at Trocadero, London.

MONDAY, FEBRUARY 20TH.

Institution of Electrical Engineers: Newcastle Section.

7.30 p.m. At Armstrong College. (1) "The Relation between Phase Displacement and Load in Alternators," by W. Firth. (2) Demonstration of Fire-damp Cut-out Apparatus.

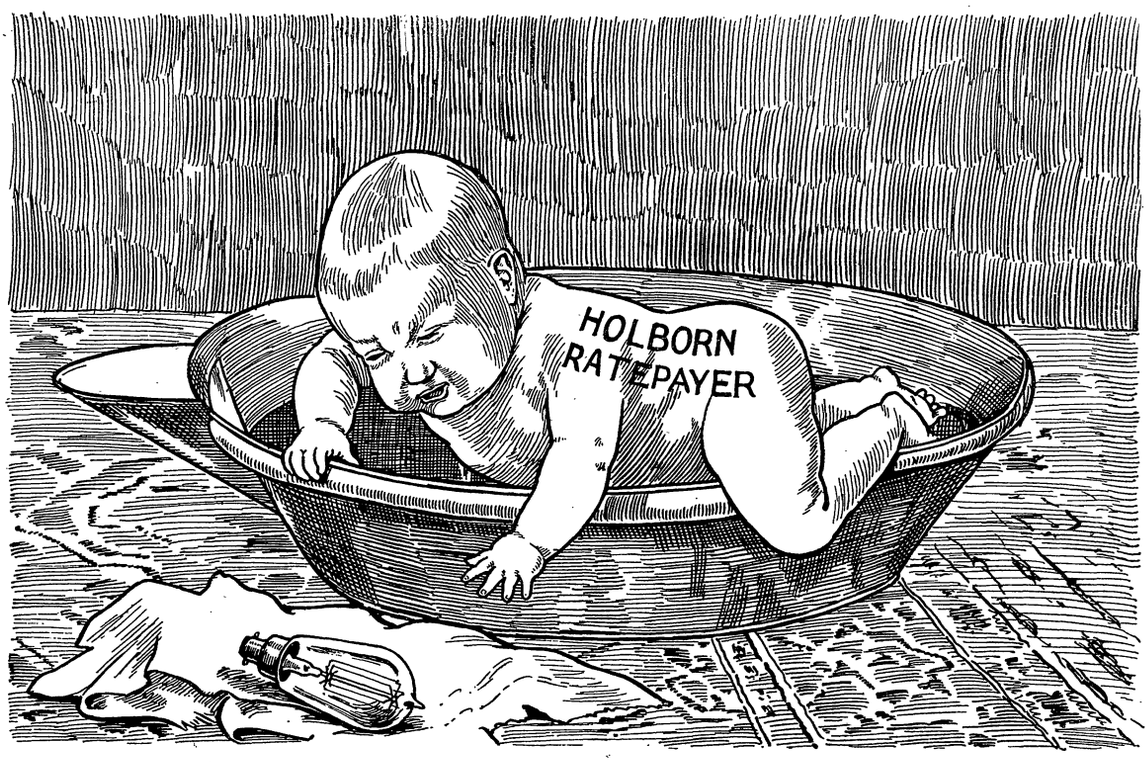
TUESDAY, FEBRUARY 21ST.

Institution of Electrical Engineers: Students' Section.

7.30 p.m. At Municipal School of Technology. "Sub-station Practice," by O. Welch and A. E. Dent.

Electro-Harmonic Society.

8 p.m. Concert (Ladies' Night) at Holborn Restaurant.



THURSDAY, FEBRUARY 23RD.

South Wales Institute of Engineers.

7 p.m. At Park Place, Cardiff. "Breaking High and Low Potential Circuits," by A. G. Collis.

Institution of Electrical Engineers.

8 p.m. Adjourned Discussion on Long-Distance Power Transmission.

"He won't be happy till he gets it."—With apologies to Messrs. A. & F. Pears, Ltd.

[Proposals for a new contract with the Gas Co. for the street lighting of the Borough of Holborn (London) have been twice referred back to the Works and General Purposes Committee by the Council, in view of the desire of the ratepayers to have electric light in the streets.—See page, 81.]

"ELECTRICAL ENGINEERING"

LITERARY SUPPLEMENT

REVIEWS OF BOOKS

Three-phase Transmission. A Practical Treatise on the Economic Conditions Governing the Transmission of Electrical Energy by Underground and Overhead Conductors. By W. Brew. 178 pp. 8¾ in. by 5¾ in.. 82 figures. (London: Crosby Lockwood & Son.) 7s. 6d. net; abroad, 8s. 1d.

We recommend Mr. Brew's book to all engineers engaged in the design or extension of three-phase systems, and we recommend it still more as a pattern to the engineer who aspires to become a writer of technical literature. There is no "padding," no unnecessary verbiage; there are no "elementary" chapters containing definitions of familiar terms and long descriptions of stereotyped pieces of apparatus and standard practice with which technical books of recent years abound. Mr. Brew addresses himself obviously to the engineer who is fully equipped both in theory and practice for his work, and he gives him the benefit of the results of his own experience, observation, and deductions in a subject of which he has made a special study. If a larger proportion of the technical books which are published were of this character, the occupation of the reviewer would be more interesting.

The book starts with an introductory chapter, in which certain commercial considerations in connection with three-phase mains are considered. This is followed by an investigation, illustrated by apposite concrete examples, into the losses in the conductor, dielectric and sheathing, and the concluding pages of this second chapter afford an excellent indication of the spirit of the book. They deal with Kelvin's law of economy, not by repeating from beginning to end the explanation and proof to be found in innumerable textbooks, but by stating it simply, and then investigating its limitations and applicability to the actual conditions of modern three-phase practice. The next chapter discusses the question of working pressures; and the chapter on switchgear which follows is the only one in which the author has succumbed to some extent to the temptation of describing more or less standard apparatus in a more or less standard manner. The next chapter treats resonance, surges, and harmonics in a way which removes the veil of mystery and mathematics so baffling to the ordinary engineer; and in the last two chapters the questions of earthing and power-factor correction receive attention. The value of every electrical engineer's library will be enhanced by the addition of this book to its shelves.

Electric Trains. By H. M. Hobart. 201 pp. 8¾ by 5½ ins. 88 illustrations. (London: Harper & Bros.) 6s.; abroad, 6s. 8d.

With the enlargement of the field of electric traction there arises more and more need for specialised treatises dealing with particular parts of the subject, and in limiting himself to electric trains (and the limitation is even narrower than the title suggests, as only multiple unit trains for urban and suburban service are dealt with), the author is able to put forward a more straightforward and complete treatment of the matter in hand than could be done in a work of wider range. The main object of the book is to put forward thoroughly practical methods of calculating the energy required for working of such electric trains and of arriving at approximate estimates for the rolling stock proportioned for a given service. Descriptions of equipment do not form part of the scheme, but valuable quantitative data of motors, &c., in use and of actual tests are included. Numerous references are, however, given to papers read and descriptive articles in the technical press.

The subject is developed with the clear logical sequence that characterises all Mr. Hobart's work. The first chapter, entitled speed-time diagrams, deals generally with accelerations, maximum or "crest" speeds, &c. The influence of the number of stops per mile, and the duration of each stop is then considered, and the conclusion is arrived at that "for high-speed trains making frequent stops, it is of great commercial advantage to employ such systems of propulsion as shall, other things being equal, consist with low total weight of train for a given seating capacity." This statement prepares the way for the comparison for single-phase and continuous equipments that follow. The preponderating influence of momentum in a service with frequent stops is then treated more fully; the amount of energy wasted in the brakes is worked out, and modifications of the calculations to take into account the losses in the electrical equipment are indicated. A method of estimating the energy consumption of the train is then gone into, and the efficiency of the electrical equipment is then taken into account. Here, of course, comparisons between single-phase and continuous equipments begin to be made, but the author remarks, "There is little to choose between continuous and single-phase equipments as regards their efficiency under conditions of actual service, but any superiority in this respect which there may be is certainly possessed by continuous equipments." As we shall see presently, Mr. Hobart's well-known condemnation of single-phase working is based more on the greater weight of the train equipment for a given service. In the chapter just alluded to is a full specification of a standard train of the Lancashire and Yorkshire Railway, and the next two chapters are devoted to actual figures relating to the Central London and Piccadilly tube railways. After a further treatment of the relations between acceleration, tractive force, and train friction, the predetermination of the power curve to a given journey is taken in hand. Some particulars follow of the Midland Railway single-phase working, and the opportunity is taken for a statement that "It will be found characteristic of single-phase railway equipments that their weight per h.p. is of the order of twice that of continuous equipments." The comparison between single-phase and continuous-current motors is further developed in a study of the watts dissipated in internal motor losses per ton weight of motor, taking data of motors actually in use for the class of service considered. Weights and costs are then treated of, and for the same cost of train per seat, the appropriate schedule speed in m.p.h. for a given service is worked out, after making certain consumptions, greatly to the disadvantage of the single-phase system, and the author triumphantly remarks, "These results show that for the railway electrification work at present confronting engineers, *i.e.*, for the range of work where electrical methods are distinctly preferable to steam locomotive methods, the system employing series-wound continuous-electricity motors is decidedly the most appropriate." This point is further elaborated in the final chapter, entitled summary and conclusion, and a plea for the 1,200-volt continuous-current system is added.

Although, as may be gathered from the above, there is a certain amount of special pleading for the continuous against the single-phase system, Mr. Hobart has not indulged in the degree of abuse of the latter and its advocates that he thought fit to include in a former work; with the result that his words carry much more conviction. With regard to minor details we are pleased to see that the author has abandoned the employment of the comma instead of the decimal point, a usage to which we have taken exception on former occasions.

Hosted by Google

A Dictionary of Electrical Engineering. Edited by H. M. Hobart. 2 vols. 648 pp. 10½ by 7¼ in. About 700 figures. (London: The Gresham Publishing Co.) 35s. net (abroad, carriage forward).

ALTHOUGH entitled a dictionary, this comprehensive work is considerably more than a mere glossary of technical terms; it contains, in the case of the more important entries, illustrated special articles, some of them a page or more in length, by contributors whose names are well known in the branches of electrical engineering upon which they write. In addition to the smaller illustrations in the text, there are also a number of full-page reproductions of photographs, which, although for the most part unnecessary from an explanatory point of view, at any rate enliven the appearance. The work is of monumental proportions, and is a production characteristic of the industry and methodical thoroughness of its compiler.

In a book such as this, the three qualities which are the best tests of its excellence are its up-to-dateness, its accuracy, and its homogeneity; but in making criticisms we must realise some of the difficulties always attendant upon work of this character. With a number of different authors some duplication is unavoidable, and even omissions may easily occur. Again, the size of the book prevents all parts of it going to press at the same moment, so that some portions are necessarily less up-to-date than others. But, nevertheless, there should have been greater uniformity in the ratio of the lengths of the articles to the importance of the subjects, and more care should have been taken to see that the illustrations were really typical of the class of article described.

Taking at random the subject of metal-filament lamps, to test the qualities laid down above as essentials, we must complain against the Osmium lamp being retained without being classed as commercially obsolete, and the omission from the list of processes on page 294 of the wire-drawing method of making tungsten filaments. Again, the "substitution process" is, we believe, no longer used commercially, and it is misleading to mention that this is covered by the patents of Just-Hanaman, whose much better-known patents refer to the paste process, in connection with which these names are not mentioned. These shortcomings are partly compensated for by the inclusion later in the book of a special heading, "Tungsten Lamps with Drawn Filaments," not bearing the initials of the same contributor, and to which there is no cross-reference in the main article. Similar examples might be multiplied, but such small faults must not be allowed to eclipse our appreciation of the merits of the way in which other subjects are handled. The switchgear articles, for instance, are excellent, and to say that those on dynamo design, &c., are worthy of Mr. Hobart's reputation is sufficient praise. Except for an occasional instance such as we have mentioned, the cross-referencing and other details of the arrangement are excellent.

General Foundry Practice. By W. Roxburgh. 296 pp. 8¾ in. by 5¾ in. 161 illustrations. (London: Constable & Co., Ltd.) 10s. 6d. net. Abroad, 11s. 2d.

IT is not too much to say that a better knowledge of the practical conditions of the foundry on the part of designers and draughtsmen would often lead to considerable manufacturing economies being effected. We think that a thorough study of a work such as this could be of great help in this direction, although, to quote the preface, it is "primarily intended for moulders and founders of every description." The whole work is thoroughly practical and bears the stamp of having been founded on many years' experience of the author as a foundry manager. More than half the pages are devoted to general iron founding, including many useful hints on starting a small foundry, and a section follows dealing in detail with loam moulding. The third division of the book treats of the casting of other metals, including brass, bronzes, speculum metal, aluminium

JUST PUBLISHED.

A DICTIONARY OF ELECTRICAL ENGINEERING

EDITED BY

H. M. HOBART,

B.Sc., M.Inst.C.E., M.I.E.E., M.Am.I.E.E.,

With the Co-operation of the following TWENTY-TWO EMINENT SPECIALISTS:—

ARTHUR H. ALLEN, A.M.I.E.E.
FREDERICK W. CARTER.
REGINALD C. CLINKER, A.M.I.E.E.

HENRY G. SOLOMON, A.M.I.E.E.
THEODORE STEVENS, M.Inst.C.E., M.I.E.E.
HAROLD D. SYMONS, A.M.I.E.E.
HENRY W. TAYLOR, A.Am.I.E.E.
FRANK WALLIS, M.A., M.I.E.E.

A Dictionary of Electrical Engineering so far transcends the uses and scope of an ordinary dictionary that it might be justly described as **An Encyclopædia.** It is designed to be more valuable than a specialised textbook, because the same subject is frequently dealt with by several specialists from different points of view, and the aspects emphasised by each expert being mutually helpful, a much better grasp of a particular problem can be attained.

A Dictionary of Electrical Engineering includes the definitions already announced by the British Committee of the International Electrotechnical Commission; also definitions from the Standardization Rules of the American Institute of Electrical Engineers and definitions from official publications of England, Germany, and America. These definitions are given in addition to those supplied by the contributors to this new and original work.

THIS ENTIRELY NEW WORK IS THE ONLY UP-TO-DATE AND COMPREHENSIVE DICTIONARY OF ELECTRICAL ENGINEERING

FIRST 5/- PAYMENT

It contains 6000 entries, nearly all important articles being signed by the writer; 700 new illustrations embellish and illustrate the definitions given. Complete in two volumes, bound in half leather (Roxburgh) containing together 648 pages. Most of the entries are short, concise and terse, but there are numerous longer articles covering special sections of electrical work.

PROSPECTUS FREE.

Messrs. CONSTABLE

are publishing a new Series of Manuals for Electricians issued in an uniform pocket size.

First Volumes Now Ready, 1/6 Net Each:

ARC LAMPS AND ACCESSORY APPARATUS.
MOTORS AND SMALL POWER PLANT.

Volumes in Preparation, 1/6 Net Each:

Mining Installations.
Mill and Factory Wiring.
Ship Wiring and Fitting.
Bells, Telephones, &c.
Testing and Localising Faults.
Lamps, Switches, Fittings, Transformers.
Conductors, House Wiring, &c.

SOLENOIDS, ELECTROMAGNETS & ELECTROMAGNETIC WINDINGS.

By CHARLES UNDERHILL, Assoc.Mem.A.I.E.E. Cloth. 218 Illustrations. 8s. net.

The rapid development of remote electric control, and kindred electro-mechanical devices wherein the electromagnet is the basis of the system, makes the need for accurate data, regarding the design of electromagnets, the more evident.

THE TELEGRAPHIC TRANSMISSION OF PHOTOGRAPHS.

By T. THORNE BAKER, F.C.S., F.R.P.S., A.I.E.E. With Illustrations and Diagrams. 2s. 6d. net. Crown 8vo.

Engineer:—"The author deals with the subject in a simple manner, and the reader will find nothing in the work which is difficult to understand."

RADIO-TELEGRAPHY.

By C. C. F. MONCKTON, M.Inst.E.E. With 173 Diagrams and Illustrations. Extra Crown 8vo. 6s. net.

PART CONTENTS:—Preface. Electric Phenomena. Electric Vibrations. Electro-magnetic Waves. Modified Hertz Waves used in Radio-telegraphy. Apparatus used for Charging the Oscillator. The Electric Oscillator. Radio-telephony Systems, &c.

APPLIED THERMODYNAMICS FOR ENGINEERS.

By WM. D. ENNIS, M.E. With 316 Illustrations. The writer presents those fundamental principles which concern the designer no less than the technical student in such a way as to convince of their importance. 21s. net.

THE CONSTRUCTION AND WORKING OF INTERNAL COMBUSTION ENGINES.

Being a Practical Manual for Gas Engine Designers, Repairers and Users. By R. E. MATHOT. Translated by W. A. TOOKEY. Medium 8vo. With over 350 Illustrations. 24s. net.

Mechanical World:—"A thoroughly satisfactory translation . . . there is no doubt as to the utility of the book, and we have much pleasure in specially commending it to the notice of designers of gas engines, and to students of the subject generally."

THE INTERNAL COMBUSTION ENGINE.

Being a Text-book on Gas, Oil, and Petrol Engines, for the use of Students and Engineers. By H. E. WIMPERIS, M.A., Assoc.M.Inst.C.E., Assoc.M.Inst.E.E. Illustrated. Crown 8vo. 6s. net.

Electrical Review:—"Will be found of great assistance to students engaged in the study of thermodynamics, as well as a record of the advances in efficiency and reliability that such knowledge and investigation has resulted in procuring."

THE PRICING OF QUANTITIES.

Showing a Practical System of Preparing an Estimate from Bills of Quantities. By GEORGE STEPHENSON, Author of "Repairs," "Quantities," &c. Demy 8vo, price 8s. net.

Contract Journal:—"The book contains a practically complete record of prices for a detached residence and a large block of flats costing £20,000."

London: 10, Orange Street, W.C.

and its alloys, &c., and the manufacture of "malleable" iron castings. Succeeding chapters deal with practical metallurgy in the foundry, pattern-making from a moulder's point of view, foundry ovens, fuels, and foundry tools. The first mentioned of these contains analyses of various brands of English pig-iron.

Practical Electrical Engineering for Elementary Students. By W. S. Ibbetson. 155 pp. 7½ in. by 5¼ in. 61 figures. (London: E. & F. Spon, Ltd.) 3s. 6d.; abroad, 3s. 7d.

THIS book contains a series of fifty laboratory experiments illustrative of elementary laws of continuous current work, and dealing with the measurement of current and resistance, fall of potential, potentiometer, and photometric measurements, and the principles of continuous-current motors and dynamos. Helpful diagrams and notes, with worked examples and curves plotted from actual readings are included, and suggestions are given for writing up the reports on the experiments. The experiments are particularly well chosen, and the book should be of considerable value as a guide to a laboratory course in technical schools.

The Development of the Telephone in Europe. By H. L. Webb, with an introduction by Harold Cox. 78 pp. 8¾ in. by 5¾ in. (London: The Electrical Press.) 1s. net; by post, 1s. 2d.

MR. WEBB'S book is an attack upon every action which the Government has taken with regard to telephony. If it obtains a wide circulation it will certainly not assist telephone engineers and officials in the difficult and delicate task which they are to have at the end of this year when the transfer of the telephone system of the country to the Post Office is to take effect. That telephone progress in this country, especially in the early days, has been seriously impeded by the action of the Government under its telegraph monopoly, can be unreservedly admitted, but we fail to see the object of stirring up animosity against Government control a few months before the Government is to become the sole owners of the telephone system. Mr. Webb's efforts would have been more praiseworthy had they been directed to showing that the Post Office telephone department have exhibited, in the work which they have carried out during the last few years, their thorough knowledge of the best practice in telephony—both local, inter-urban, and international. He could, moreover, have added with justice that as the Department will be in a position to avail itself of the services of the expert staff of the National Telephone Co., as well as of their own, and should be able to obtain wayleave facilities which have not been accorded to the Company, there is every reason to expect that telephony will make rapid and unprecedented progress when the transfer is completed, if the enterprise is not hampered by parsimony or indifference on the part of the Treasury or by hostility and hyper-criticism on the part of the public. The future of telephony in this country during the next decade will largely depend upon the smoothness with which the impending transfer is effected, and this in its turn will be controlled to an enormous extent by the attitude of the public while this difficult work is being carried out. Those who have the interest of the telephone industry at heart will not thank Mr. Webb for his book.

International Language and Science. Considerations on the Introduction of an International Language into Science. By L. Couturat, O. Jespersen, R. Lorenz, W. Ostwald, and L. Pfaundler. 87 pp. 8¾ in. by 6 in. (London: Constable and Co., Ltd.) 2s. By post 2s. 3d.

SEEING that the names of Ostwald and Lorenz appear on the title-page, we are bound to take this treatise seriously. It puts forward the claim for the adoption of an international language "ido," which is a development of or improvement on "esperanto." Much ingenuity has been expended on its creation, but we are bound to say that we should regret its adoption even to a limited extent as a medium for scientific or technical

Hosted by Google

communication. Professors Ostwald and Lorenz both admit that a large proportion of the scientific and technical terms commonly employed are practically identical in all languages, and we can read between the lines of Prof. Ostwald's contribution that he realises that serious difficulties would have to be overcome in adapting "ido" for scientific literature. He gives one instance which is typical: Chlorine or chlor is inadmissible, for in "ido" ch has only one pronunciation—as in "church"—and the spelling clorine would also be impossible, as c is to be pronounced as ts; yet the symbol Cl must be retained. It is evident that there would be a large number of other terms already accepted in all languages that would have to be modified out of all recognition in order to conform with the spelling conventions of "ido." We are bound, however, to point out an even more serious objection to the employment of a new language by men of science and engineers, viz., the impossibility of ensuring absolute accuracy of expression and of avoiding ambiguity, and we have in the book itself an example ready to hand to illustrate our point. In one of the appendices a passage from an English book has been translated into "ido" by one expert and translated back again into English by another. In this, the expression "in print" becomes on re-translation "in the course of printing." If two such different ideas as these are expressed in the same words in "ido," one cannot imagine that it would be suitable either for scientific or technical literature or for engineering specifications.

Electric Motors. By F. B. Crocker and M. Arendt. 291 pp., 9¼ in. by 6¼ in., 158 figures. (London: Crosby, Lockwood & Son.) 10s. 6d. net; abroad, 12s. 2d.

ALTHOUGH this book is undoubtedly a good compendium of American practice, we do not find any very distinguishing feature to lift it, in point of utility to English readers, above the group of books written in this country dealing partly or wholly with electric motors. While it professes to deal more particularly with the operation of motors as distinct from their design and construction, the text may be described as somewhat academic in nature, dealing chiefly with the theory of characteristic curves and the various methods of control of D.C. and A.C. motors, nor does it cover very much new ground. American practice in electric driving is very similar to English practice, but there are some types of variable-speed motors described which are never seen in this country. This, however, rather adds to than detracts from the interest. In common with most American text-books, there is a disadvantage to English readers in the use of American rules and standards.

A Text-book of Physics. By H. E. Hurst and R. T. Lattey. 638 pp. 8¾ in. by 5½ in., 101 figures. (London: Constable & Co.) 8s. 6d. net; abroad, 9s. 6d.

IN the preface it is stated that the original intention was to cover the syllabus of the Preliminary Examination in Physics in the Oxford Natural Science School, but that "a certain amount of additional matter has been introduced." The authors are to be congratulated at once upon their modesty and upon the excellence of their work. For all examinations up to the standard of the Intermediate Science of London University, this is one of the most suitable books we have seen; moreover, it is exactly the kind of work that ought to be in the hands of engineering students. The various sections are:—Mechanics, Heat, Sound, Light, Magnetism, Statical Electricity, Current Electricity, and Mathematical Notes and Tables. While the treatment of the "pure science" is admirable, the authors have not been quite so happy when dealing with more technical matters, which, however, occupy very little space, and might, perhaps, have been omitted without detracting very much from the value of the book as a whole.

Matriculation Magnetism and Electricity. By R. H. Jude and J. Satterley. 415 pp. 7 in. by 5 in. 237 illustrations. (London: University Tutorial Press.) 4s. 6d.

ALTHOUGH the title of this work would lead one to expect a text-book limited to the requirements of those preparing for one particular examination, in reality a wide course is covered. The elementary principles of electricity and magnetism are explained and illustrated by a large collection of simple experiments, adapted to school requirements, and requiring only simple apparatus. In general, the text follows the lines of Dr. Jude's *School Magnetism and Electricity*, on which the present book is based, but both experiments and diagrams have been increased in number. The principles of magnetism are dealt with before those of electrostatics, as various phenomena common to both, such as the law of inverse squares and the conception of lines of force, are demonstrated more easily by practical methods in magnetism than in electricity. A useful feature of the book is the large number of diagrams of lines of force and equipotential surfaces. The latter portion of the book deals with primary and secondary cells, Ohm's Law, and the principles of electromagnetic induction, but in common with many text-books of the old school based on examination schedules, the prominence given to the properties of electric currents is considerably less than that given to out-of-the-way electrostatic phenomena.

LEWIS'S CIRCULATING SCIENTIFIC LIBRARY

Comprises a large collection of Scientific and Technical works dealing with Electricity, Engineering (Electrical, Mechanical and Civil), Metallurgy, Chemistry, Geology, Physics, etc., etc.

The library is invaluable to Electrical Engineers desiring to consult works on their own or allied subjects.

Annual subscription Town or Country from one guinea.

Reading Room open daily to subscribers.

Lewis's Quarterly list of New Books and New Editions added to the Circulating Library, with nett prices and postages, will be sent post free on application.

Practical Curve Tracing. By R. Howard Duncan. 133 pp. 8¾ in. by 5½ in. 77 illustrations. (Longmans Green & Co.) 5s. net; abr., 5s. 4d.

GRAPHICAL methods are employed both in practise on account of their convenience and for educational illustration on account of their clearness to such a large extent that one of the most essential parts of the mental equipment of an engineering student is a thoroughly clear idea of the meaning, properties and uses of curves. The author of the work has provided a very clear and useful introduction to the subject, forming an excellent bridge between the algebraic and the graphic aspects of the relations of variables, without going very deeply into their academic treatment either from the analytical or the geometrical side. The properties of the straight line, parabola, hyperbola, sine, logarithmic and exponential curves are clearly dealt with, and a useful chapter follows on the graphical solution of equations. An admirable sketch developing the ideas of differentiation and integration from the slope and areas of curves is contained in the final chapters. This, although brief, forms a much better introduction to a part of mathematics in the attacking of which difficulty is often found, than is given in many of the more orthodox text-books.

Elektrische Beleuchtung. By Dr. Ing. Berthold Monasch. Second edition, enlarged. 331 pp. 8¾ in. by 6 in. 112 illustrations. (Hanover: Max Jänecke.) Paper cover, 9s. 3d.; cloth, 10s.

THE greater part of this book is apparently a mere reprint of the first edition, which appeared in 1906; it contains some statements which are, at the present time, erroneous and misleading, and descriptions of obsolete types of lamps are retained. Some 100 pages have been added, however, as a "second part" to cover the progress of the last four years, and the matter in this is mainly a collection of useful abstracts of the more important contributions to the technical papers of Europe on the subject of illumination. Brief descriptions of one or two recent types of arc lamps are included, and the section on metal filament lamps is quite up-to-date, embracing much information as to their behaviour, properties, and economy. The various methods of manufacture are only briefly referred to.

Applied Mechanics for Engineers. By John Graham. 304 pp. 7¼ ins. by 4¾ ins. 246 figures. (London: Edward Arnold.) 5s. net; abroad, 5s. 5d.

THIS is an excellent text-book, presenting the elements of the essential parts of the subject in a most concise form. The clearness of the text and the frequent use of worked examples make it suitable for home study. Sections are included on graphical statics, roof structures, beams and girders, problems connected with the flow of water, and the theory of the steam engine. The chapter on balancing, written on the lines adopted by Prof. W. E. Dalby, should be found of considerable use. The general method of treatment in the book is graphical, but a knowledge of the elementary calculus is presumed.

Notes on Applied Mechanics. By R. H. Whapham and G. Preece. 203 pp. 7¼ ins. by 4¾ ins. 150 figures. (London: Edward Arnold.) 4s. 6d. net; abroad, 4s. 10d.

THESE notes are primarily intended for the use of naval cadets on the training cruisers after the completion of their course at Dartmouth.

Spon's Architects' and Builders' Pocket Price Book and Diary, 1911. 352 pp. 6¼ in. by 3½ in. 2s. 6d. net; by post, 2s. 8d.; Memoranda Section, 372 pp., 2s. 6d. net; by post, 2s. 8d. (London: E. & F. N. Spon.) The two sections, post free, 5s. 3d.

THE issue of this well known pocket-book in two volumes is due to the thickness becoming inconvenient for pocket use in consequence of the addition of much new matter in the Memoranda section. The diary is included in the Prices section, the latter being the one more generally required. Among the tables of "Measured Prices" for general building and house decoration work are some for estimating the cost of wiring and of lighting installations revised for metal filament lamps, and a complete specification of a country-house installation is given, together with some useful general notes on electric lighting in the Memoranda section. Some twelve closely-printed pages are devoted to extracts from the Wiring Rules of the Institution of Electrical Engineers. The general information in the Memoranda section with regard to building law, fire insurance, &c., is of considerable value.

The Local Government Annual and Official Directory, 1911. (20th year.) 296 pp. 7 in. by 4¾ in.. (London: "The Local Government Journal" Office.) 1s. 6d.

THE 1911 edition of this directory has been revised and brought up to date with the thoroughness characteristic of the publishers. To anyone seeking information relating to Local Government, the book is invaluable. In addition to lists of Committees, &c., the useful particulars of the various undertakings of the London boroughs, including electric supply, and the abstract of the Local Government legislation of 1910, cannot fail to be of the greatest service.

Rugby Engineering Society Proceedings. Vol. VII. 112 pp. 8¼ in. by 5½ in. 8 figures. (Rugby Engineering Society.) 10s. 6d.

THIS volume contains a Paper on "Shop Testing of Direct and Alternating Current Machinery," by J. W. Rogers, abstracted in ELECTRICAL ENGINEERING, Vol. V., p. 992, and others on the "Electric Furnace," by J. Harden, and on "The Design and Construction of Aeroplanes," by J. P. Chittenden and L. H. Robinson. Full reports of the discussions of these Papers are included.

The Practical Electrician's Pocket Book and Diary, 1911. 363 pp. 5¼ in. by 3½ in. Many figures. (London: Rentell & Co.) Cloth, 1s. net; by post, 1s. 2d.. Leather, 1s. 6d. net; by post, 1s. 8d.

THIS pocket book is too well known to need any introduction. The 1911 edition has been carefully revised by Mr. H. T. Crewe, and some additions have been made. The list of central stations now includes the names of the chief engineers. A section on armature repairs has been added, and the portion dealing with arc lamps has been entirely re-written.

Hazell's Annual, 1911. 592 pp. 7½ in. by 4¾ in. (London: Hazell, Watson and Viney, Ltd.) 3s. 6d.; abroad, 4s. 1d.

AMONG the innumerable details of information given in this yearbook, the electrical industry finds a place, the past year's happenings and future tendencies being recorded in concise language. The vast amount of information given upon practically every subject of interest to the average individual renders a book of this description indispensable, at any rate to business men.

Who's Who, 1911. 2,246 pp. 7¼ in. by 4¾ in. (London: A. and C. Black.) 10s.; abroad, 11s.

WITH some 23,000 biographies, "Who's Who" makes its appearance for 1911, as complete a guide as ever to the men and women of the day.

Englishwoman's Yearbook and Directory, 1911. Edited by G. E. Mitton. 384 pp. 7¼ in. by 4¾ in. (London: A. and C. Black.) 2s. 6d.; abroad, 3s.

THIS volume, which is in its thirtieth year of publication, deals with the woman's side of educational, professional and social matters.

Writers' and Artists' Year Book, 1911. 132 pp. 7¼ in. by 4¾ in. (London: A. and C. Black.) 1s.; abroad, 1s. 2½d.

THIS directory for writers, artists, and photographers, covers some of the ground dealt with by the ordinary press directories, but it gives a considerable amount of additional information not to be found in the latter, and yet which is indispensable to those to whom it appeals.

NEW EDITION. Thoroughly Revised by **W. SLINGO**, assisted by **T. F. WALL, M.Sc.** With 389 Illustrations.
Crown 8vo. **12s. 6d.**

ELECTRICAL ENGINEERING

FOR ELECTRIC LIGHT AND POWER ARTISANS AND STUDENTS.

By W. SLINGO and A. BROOKER.

LONGMANS, GREEN & CO., 39, Paternoster Row, LONDON, E.C.

Hosted by Google

NEW PUBLICATIONS

We shall be pleased to send any of the undermentioned works to addresses in the United Kingdom, at the net prices quoted. The price for sending to the Colonies and abroad is also quoted when there is an increase. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203–6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

"The Slide Rule." By C. N. Pickworth. 12th edition. 118 pp., 7¼ in. by 5 in., 34 figures. (Manchester: Emmott & Co.) 2s. net; by post, 2s. 3d.

"Logarithms for Beginners." By C. N. Pickworth. 3rd edition. 47 pp., 7¼ in. by 5 in. (Manchester: Emmott & Co.) 1s.; by post, 1s. 2d.

"Spons' Architects' and Builders' Pocket Price-Book and Diary, 1911." 352 pp., 6¼ in. by 3½ in. 2s. 6d. net; by post 2s. 8d. Memoranda Section. 372 pp. 2s. 6d. net; by post, 2s. 8d. (London: E. & F. N. Spon.) The two sections, post free, 5s. 3d.

"Applied Thermodynamics for Engineers," by W. D. Ennis. 438 pp., 10in. by 6½in., 316 figures. (London: Constable & Co) 24s. net; abroad, 25s. 3d.

Transactions of the Institution of Engineers and Shipbuilders in Scotland, Vol. LIII., Session 1909-10. 429 pp., 8½in. by 5½in., numerous figures and plates. (Glasgow: The Institution Offices, 39, Elmbank Crescent.)

"The Law Relating to the Generation, Distribution, and Use of Electricity, including Electric Traction." By C. M. Knowles. Part I., "Electric Lighting and Power," pp. 447; Part II., "Electric Traction," pp. 403; 9¾ in. by 6¼ in. (London: Stevens & Sons.) Price, two vols., 42s.; abroad 43s. 8d.

"Gas Engines." By W. J. Marshall and Captain H. R. Sankey, R.E. 278 pp. 8¼ in. by 5½ in., 127 figures. (London: Constable & Co.) Price 6s. net; abroad 6s. 8d.

"Engineering Mathematics." By C. P. Steinmetz. 292 pp. 9¼ in. by 6 in., 93 figures. (London: McGraw-Hill Book Co.) Price 12s. 6d. net; abroad 13s. 2d.

"The Law Relating to Electrical Energy in India" (The Indian Electricity Act, 1910). By J. W. Meares. 426 pp. 9½ in. by 6¼ in. (Calcutta: Thacker, Spink & Co.) Price 15s. net; abroad 15s. 11d.

"Three-Phase Transmission." By W. Brew. 178 pp. 8¾ in. by 5¾ in. 82 figures. (London: Crosby Lockwood and Son.) 7s. 6d. net; abroad, 8s. 1d.

"The Development of the Telephone in Europe," by H. L. Webb, with an Introduction by Harold Cox. 78 pp. 8¾ in. by 5¾ in. (London: The Electrical Press.) 1s. net; by post, 1s. 2d.

"A Dictionary of Electrical Engineering." Edited by H. M. Hobart. 2 vols. 648 pp. 10½ in. by 7¼ in. About 700 figures. (London: The Gresham Publishing Co.) 35s. net; abroad, carriage forward.

"The Universal Electrical Directory (J. A. Berly's), 1911." 1,552 pp. 9¾ in. by 6¼ in. (London: H. Alabaster, Gatehouse & Co.) *A.* British and Colonial Sections only, 10s.; abroad, 11s. *B.* British and Colonial, with Continental and U.S.A. Sections, 14s. 6d.; abroad, carriage forward.

Lewis's Scientific Circulating Library.—Mr. H. K. Lewis has sent us a list of the latest books and additions added to his circulating library, a library which should be found of particular interest to those of our readers who require from time to time to consult standard works on not only electrical engineering, but also on allied subjects. The library now comprises some 15,000 standard works of a scientific character. Mr. Lewis informs us that a new supplement to the library catalogue is now in the press, which will include about 2,000 new titles. In connection with the library at Gower-street, a very well appointed reading-room is provided, where subscribers can, at their ease and convenience, refer to any of the works included in the catalogue.

The Central.—The current issue of the Journal of the Central Technical College Old Students' Association contains an article on the educational and social activities of the college session 1909-1910, and the usual interesting Old Students' Notes. Among the special articles is an account by Prof. W. J. Pope of researches on the structure of crystals and its relation to chemical constitution. A description of the new engineering laboratories of the College is written by Prof. W. E. Dalby. These shops include apparatus to be used in connection with the advanced courses in electric traction, and a dynamometer pit for testing tramcar trucks and electric power signalling equipments have already been installed. The other features of this number are articles on the cross-Channel steamers, the bonus system in a machine shop, and the development of the Humphrey pump. Excellent photographs of Mr. M. A. Bullock, Secretary of the Students' Union, and Mr. E. S. Hoare, Secretary of the Engineering Society, are included.

"ELECTRICAL ENGINEERING" LIST OF SELECTED TECHNICAL BOOKS.

We shall be pleased to send any of the following books to addresses in the United Kingdom at the *net* published prices named, unless otherwise stated. The increased price for sending abroad is also quoted after each book. All the books listed have been recommended by our editorial staff and reviewers.

Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-206 Temple Chambers, Temple Avenue, E.C. and should be accompanied by a remittance.

LIGHTING IN THE BOROUGH OF HOLBORN

Committee's Recommendation for Gas Lighting Rejected

THE Holborn Council Works Committee seem determined to achieve notoriety over the lighting of the borough by their remarkable insistence in recommending gas lighting against the wishes of their own ratepayers and in the face of an offer from the electricity supply companies which will effect a saving of nearly £1,000 a year.

In July, 1910, an offer was made by the Gas Light & Coke Co. to instal and maintain an improved system of gas lighting in the majority of the thoroughfares for £6,688 per annum on a ten years' contract, a total candle-power of 260,000 being guaranteed. This was recommended for acceptance by the Committee, but the Council refused to accept the offer, and, after receiving a deputation of shopkeepers, headed by Mr. A.W. Gamage, desired information as to the comparative merits and cost of gas and electricity. Accordingly, in October last year, competitive demonstrations were given in Gower Street by the Gas Light & Coke Co. on the one hand, and the Metropolitan, County of London, and Charing Cross and West End Electric Supply Companies on the other; the Metropolitan Electric Supply Co. conducted the electric-lighting experiment on behalf of all three electric-lighting companies. Photometric tests taken at angles of 20° and 50° to the horizontal showed that the electric lamps were giving an average of 395 c.p. each, and the gas lamps 318 c.p. each. Readings taken in the centre of the roadway showed that there was very little difference between gas and electricity; the specification required that each lamp should give at least an average candle-power of 300 at the two angles. After this experiment the companies were invited to submit tenders for lighting the borough according to a schedule of prices per annum for lamps of different candle-power ranging from 60 to 2,000 c.p. each. The tenders were on the basis of a ten years' contract, subject to the Council having the option of determining it at the end of the first five years on payment of a proportion of the capital charges, estimated at from £2,500 to £3,000. Each company undertook to provide all services, lamps, columns, fittings, painting, and attendance, together with the necessary supply of electricity or gas. The Works Committee, in their report on the tenders, suggested 2,000-c.p. lamps in High Holborn and New Oxford Street, 600-c.p. lamps in Tottenham Court Road, 400-c.p. lamps in the other main thoroughfares, and 60-c.p. lamps in all other streets, and estimated that 405,000 c.p. would be required. It may also be mentioned that there are a certain number of streets at present lighted by gas, for which the contracts have not yet expired.

The respective tenders for electricity and gas were £6,602 and £7,527. And here comes the amazing part of the whole affair, for the Works and General Purposes Committee, at the meeting of the Borough Council last week, gravely recommended the Council to accept the tender of the gas company at £7,527 per annum—higher by £9,250 than the tender for electricity over the ten years' contract. The only reasons adduced were that it would not be advisable to have two systems of illumination in the borough, that there would be less interference with the streets, and that the difference in cost was not sufficiently great to warrant a radical alteration in the system of lighting.

Subsequent events in the Council Chamber demonstrated, fortunately, that it is only the Works Committee who are able to view £9,250 as a trifling sum. The subject has created such interest among the Councillors of Holborn—not to mention the ratepayers—that the Council meeting on Wednesday last week, when the matter was considered, was in distinct contrast to the air almost of lethargy which usually prevails. Mr. Max Clarke, the Chairman of the Committee, introduced the report with no more cogent reasons for accepting the recommendation than those mentioned above. One point made by him told rather against the Committee than otherwise—viz., that the Gas Light & Coke Co. intend to lay a high-pressure main down the middle of High Holborn and New Oxford Street, so that, as far as interference with traffic is concerned, it can hardly be claimed that there will be less than with electricity, as mains are laid in most of the Holborn thoroughfares, and the bulk of the street work would be under the pavements. The Chairman of the Works Committee expressed his indifference as to which way the Council voted, giving it as his opinion that the borough is well enough lighted at present; some other members held the same views. But the Chairman of the Committee followed this up by a statement not in accordance with facts—that many other boroughs in London had given up electricity for gas after having found it unsatisfactory, including some boroughs owning electricity works. He delegated to another member of the Works Committee, Councillor Edward Angel, the task of reading a list of these boroughs—a list prepared, he said, by the Holborn Borough Surveyor—and our surprise may be imagined when we heard the names of Bethnal Green, Chelsea, Lambeth, and Finsbury, as well as notorious Westminster, the vacillating City of London, and Paddington, with its one half-hearted single-street experiment. No mention was made of Hampstead and Shoreditch, in which electricity is entirely superseding gas for street lighting; and as for Marylebone, where the substitution of electricity for gas is complete, Mr. Angel actually said that some streets were lighted by gas. Councillor Fitzroy Doll, also a member of the Works Committee, testified that Chelsea have never had electric light in their streets. We can inform the Holborn surveyor that Bethnal Green has never had a supply of electricity in their borough at all, the statement as to Lambeth and Finsbury is hopelessly inaccurate, and in the other three districts the displacement of electricity by gas is either partial or temporary. The debate resolved itself into there being one or two members in favour of gas, a large majority in favour of rejecting the Works Committee's report and accepting the tender for electricity, and a few members who sat on the fence, with no fixed opinions of their own, and who practically admitted they would vote whichever way their constituents desired. The Committee's action in recommending the highest tender after requesting the electric light companies to tender and putting them to the expense of the experimental lighting was referred to by more than one speaker as an insult to the Council and the companies. One member thought the Council would be pilloried by the whole of London if gas were adopted. Others thought the matter ought not to be rushed through, but when those opposed to the recommendation insisted on a vote, which would undoubtedly have resulted in the electric light tender being accepted, the Chairman of the Works Committee pleaded that, as the contract with the gas company terminates on March 25th, there would not be time to carry out the change over before that date if the electric light tender were adopted. The fear of the Borough of Holborn being left in darkness for a certain period silenced those in favour of electric light, and the report was sent back to the Committee with instructions to bring up a new report within a month.

Hosted by Google

The gas company may be congratulating themselves that in a month's time it will be too late to change the arrangements, as it would then be necessary to put in electric lighting within a few days if it is to be done before the expiry of the present gas contract. We trust, however, that a way out of this difficulty will be found, for otherwise not only the Works and General Purposes Committee, but also the Council themselves deserve severe censure for letting this matter, which has been under discussion for about nine months, to be postponed until it is too late to adopt the only course which will be satisfactory to the ratepayers.

ELECTRICITY IN MINES

THE report has been published of the special departmental committee appointed by the Home Secretary to inquire into the working of the existing special rules for the use of electricity in mines, and to consider the advisability of their amendment. It will be remembered that the committee consists of three members, namely:—Dr. R. A. S. Redmayne, H.M. Chief Inspector of Mines; Mr. C. H. Merz; and Mr. R. Nelson, H.M. Electrical Inspector of Mines. The report consists of some seven pages of general comment on the working of the rules, to which is appended a revised code of twenty special rules, together with various forms for notifying the installation of electrical apparatus, &c., which are suggested by the committee. A memorandum of ten pages deals with certain practical points, which, it is thought, may arise in connection with the rules. The report concludes with a list of fatal accidents resulting from the use of electricity in coal mines, together with the circumstances of each accident. Perhaps the most noteworthy feature of the revised rules is the prohibition of the use of electricity where, on account of the risk of explosion, such use would be dangerous. Other new features are the provision that inflammable material shall not be used in the construction of motor rooms, more stringent regulations as regards the earthing of the outer coverings of apparatus and the conditions to be fulfilled by switchgear and machinery, and the provision for proper supervision of plant. It is recommended that the special rules should apply to metalliferous mines, as well as to coal mines. We shall deal with this report at some length in our next supplement on Electrical Engineering in Mines.

The Society of Engineers.—Among the premiums presented at the opening meeting of the session on February 6th was one to Mr. A. H. Allen for a Paper on "Electricity from the Wind."

The Electrical Standardising, Testing & Training Institution.—Mr. Robert Hammond will begin a course of lectures to the senior students of Faraday House on Tuesday, February 21st, upon "Electricity Undertakings."

Physical Society.—We are informed that Papers read before the Physical Society of London in future will appear in general only in the "Proceedings" of the Society, and not in the *Philosophical Magazine*. "The Electrician" Printing and Publishing Company, Ltd., will publish the "Proceedings."

Institution of Electrical Engineers.—The following is the result of the ballot of new members at the Institution on Thursday:—Members: A. Dow, Dr. Max Kahn. Associate Members: J. G. Balsillie, W. F. Bartram, W. H. Bray, J. G. Hill, J. McCarthy, A. McKay, F. Mellor, H. A. Neale, C. Powell, W. Rogers, J. Russell, G. Schauli, G. Smyth, F. Talboys, J. Tarby, H. Trent, W. White, A. Williams, J. Wright. Associate: J. Webb. Students: F. Baxter, C. Cosens.

New Telephone Exchange in the City.—Considerable progress has been made with the new Post Office exchange in Creechurch Lane, E.C., which is necessitated by the rearrangements attendant upon the transfer of the telephone system to the Post Office at the end of this year. The building is practically complete, and the equipment, which is for 8,000 subscribers, is about to be installed by the Peel-Conner Telephone Works, Ltd. There will be 3,000 keyless junction lines, 36 per operator, and some new features in the multiples at the calling positions.

Systems of Wiring.—We published a note relating to the "Stannos" system of wiring on page 73 of our last issue. In it we said that "'Stannos' wires are used most extensively on the two-wire system in both continuous- and alternating-current districts, and Messrs. Siemens hold that the suggestion that two wires are unsuitable for an alternating supply, owing to eddy currents being set up in the metallic casings, is quite fallacious." Messrs. Siemens Bros. & Co. inform us that not only do they hold that this suggestion is fallacious, but that it has been proved to be so by exhaustive tests and actual experience.

THE ELECTRICAL EXHIBITION AT OLYMPIA

THE first meeting of the Advisory Committee of the Electrical Exhibition, convened by the National Electrical Manufacturers' Association, which is to be held at Olympia next September, was held at the Institution of Electrical Engineers on Wednesday, February 8th, to discuss the following matters:—The types of electrical exhibits best calculated to attract a large attendance of the public, in addition to the exhibits made by the manufacturers; to decide as to the best methods of inducing visits to the Exhibition by likely users of electricity, and the different methods required in the various localities supplied by the authorities; and to make suggestions as to the best means of making the Exhibition known to Colonial and foreign buyers.

There were present:—Messrs. S. W. Baynes (St. Pancras Electricity Department), F. A. Bond (Battersea Electricity Department), E. Calvert (Finchley Electricity Department), C. B. Clay (National Telephone Co.), G. H. Cottam (Hampstead Electricity Department), S. T. Dobson (St. James & Pall Mall Electric Lighting Co.), R. S. Downe (Brompton & Kensington Electric Supply Co.), B. G. Drummond (Hendon Electric Supply Co.), A. L. C. Fell (L.C.C. Tramways), G. Horley (Westminster Electric Supply Co.), J. Douglas Knight (Ealing Electricity Department), H. W. Miller (Kensington & Knightsbridge Electric Lighting Co.), E. Cunliffe Owen (Metropolitan Electric Supply Co.), G. W. Partridge (London Electric Supply Co.), W. J. D. Partridge (Wesminster Electric Supply Co.), C. Newton Russell (Shoreditch Electricity Department), A. Hugh Seabrook (St. Marylebone Electricity Department), R. W. Sprunt (South London Electric Supply Co.), Norman Staniland (Hornsey Electricity Department), and C. H. Wordingham. The following gentlemen regretted their inability to attend:—Sir Irving Courteney, Messrs. F. Bailey, E. Garcke, T. E. Gatehouse, J. Gavey, J. S. Highfield, J. Swinburne, and W. C. P. Tapper.

Mr. E. Cunliffe Owen addressed the meeting from the chair, pointing out the desirability of exhibits of the character of X-rays, wireless telegraphy, and high-tension currents for use in agriculture as being of the class that would interest the general public. These suggestions were discussed, and as regards electric cooking, it was urged that an endeavour should be made to induce the caterers to do their cooking electrically, and to obtain the necessary apparatus from exhibitors. It was proposed that the caterers be arranged with to supply tea in a separate room, in which the visitors should be allowed to make their own tea, toast, &c., all the operations being done electrically. Attention was drawn to the attractiveness of electrical advertising signs, and it was pointed out that a telephone exchange in the Exhibition should be of great public interest. Among other exhibits proposed were a model laundry in work, electrical furnaces, and demonstrations of electro-medical apparatus. The view was entertained that it would be of great interest to members of the medical profession if a conference could be arranged, and addresses given during the run of the exhibition on the use of electricity for medical purposes. A desire was expressed by several present that the Institution of Electrical Engineers should hold a meeting at the Exhibition, and the Secretary stated that he would communicate with the Secretary of the Institution of Electrical Engineers in the hope that such an arrangement can be made.

The subject of giving publicity to the Exhibition by the supply authorities was next considered on the basis that they should purchase tickets for distribution to the consumers of electricity in their various districts. The Exhibition authorities also stated that they would be prepared to supply posters and literature, which could be distributed by the supply authorities. This suggestion was favourably received, and a request was made that a letter containing full details of this proposal should be sent to all supply authorities, with a view to the matter being formally considered by each. The meeting considered that everything possible should be done to make the Exhibition known to Colonial and foreign buyers, and it was proposed that the attention of the Board of Trade and the Chambers of Commerce should be called to the matter.

Advertising Electricity.—A conference has been held by the London Electric Supply Authorities, at which it was decided to endeavour to raise a fund of about £1,500 for advertising, including an extended display of large-size posters on the principal hoardings throughout London. Borough Councils and companies are being invited to subscribe *pro rata* towards this expenditure.

L.C.C. Tramways and Railway Signals.—The South-Eastern & Chatham Railway Co. have made a claim of £241 14s. against the L.C.C. Highways Department for providing metallic returns to certain signalling circuits on their line, owing to the interference with the signals by the overhead system of the Council from Loughborough Junction to Norwood. It will be remembered that a similar difficulty recently arose between the Council and the London, Brighton and South Coast Railway Co., and as there is a probability of such claims becoming more frequent, the Council have decided to oppose the present claim in order to obtain a decision on the legal points involved.

A NEW AUTOMATIC VOLTAGE REGULATOR

A DEMONSTRATION was recently given at the Hylton Road station, Sunderland, by the courtesy of Mr. A. S. Blackman, the Borough Electrical Engineer, of a new automatic voltage regulator possessing some interesting features which has been developed by Mr. H. M. Taylor (Borough Electrical Engineer, Middlesbrough), and his assistant, Mr. R. H. Scotson. The need for such an apparatus was felt by them in connection with the operation of a feeder booster regulating the voltage of supply to a long feeder, and at Middlesbrough the Taylor-Scotson system of control has been for a considerable time regulating the "boost" of this machine with reference to a point on the network two miles from the generating station. As the network is connected up solidly throughout, the voltage of supply throughout the system is thus automatically controlled. Another application of the gear has been made at the steelworks of Messrs. Bolckow, Vaughan & Co., Ltd., in connection with exhaust steam turbines, running on heavily fluctuating load.

The apparatus consists essentially of a small shunt-wound generator in series with the exciter field. The field of this generator is divided into two equal windings, fed from any suitable direct current supply, and arranged so that the two halves are in opposition. These fields are supplied through lamp resistances in order to eliminate sparking in the operation to be described. The armature can thus give either an opposing or an assisting boost to the terminal pressure on the exciter field, according to the half of the field which is placed in circuit. This effect is produced by short-circuiting the terminals of either half of the auxiliary field winding by a solenoid-controlled switch, the connections of which are shown in Fig. 1, where *E* is the main exciter, *A*

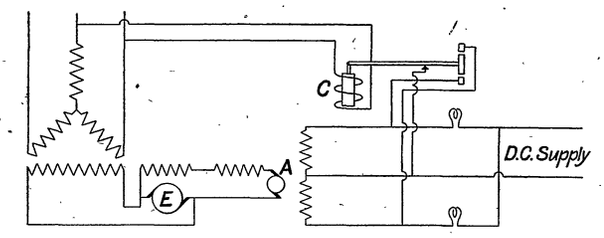

FIG. 1.—DIAGRAM OF CONNECTIONS.

the auxiliary generator armature under the influence of the divided field, and *C* is the controlling solenoid. This solenoid is a pressure coil placed across any point on the main supply at which it is required to maintain constant potential, and the position of the core depends, therefore, on the current in the solenoid *C*. This short-circuit method does away with all sparking at the points of contact. At Messrs. Bolckow, Vaughan's the gear has been working on a 24-hour day for a long period without any overhauling or adjustment, while the station superintendent at Sunderland reports that the gear there has worked since its installation without any adjustment. No attempt is made at graduating the boost in either direction. The whole of the positive or negative boost is given to the exciter field circuit at once, and this makes the gear very accurate and speedy in action. Fig. 2 shows a typical portion of a voltage chart furnished

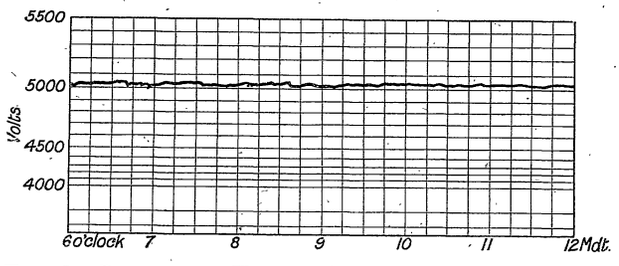

FIG. 2.—PORTION OF VOLTAGE CHART WITH REGULATOR IN ACTION.

us by the courtesy of Mr. Blackman, and the variation of voltage throughout the whole day did not exceed 0·5 per cent. on either side of normal. We are told that before the installation of the automatic control, it was difficult to keep within 1½ per cent. deviation with the most rigid hand-control.

We have given in Fig. 3 a daily load-curve at Sunderland plotted from board readings taken every half-hour, illustrating the combined lighting, tramway, and shipyard power load. The heavy changes of load at meal-times are apparent; during our visit, the load fell from about 2,600 kw. to 1,500 kw. in about eight minutes due to the shipyard dinner-hour. The engine was regulated for speed, but otherwise no voltage regulation by hand was effected, except at the moment of taking a machine out of parallel. In addition

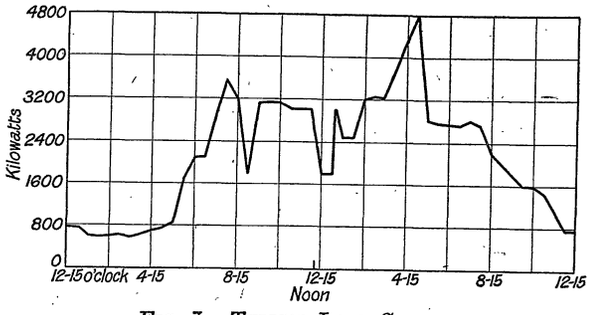

FIG. 3.—TYPICAL LOAD CURVE.

to the changes of load shown in the chart there were momentary rushes of power of as much as 500 kw., but the automatic regulator successfully dealt with these short-period fluctuations as successfully as with the slower ones.

The Bolckow-Vaughan equipment controls each or all of three 1,000-kw. exhaust steam turbines, running on a load varying from 200 kw. to over 1,000 kw., and having at times a power factor as low as 65 per cent. The motor-generator is of about 2 h.p., and is capable of giving a boost of 120 volts on a 200-volt circuit, but to meet the conditions of a short-circuit, where automatic maintenance of voltage is undesirable, an auxiliary contact comes into play on an excess movement of the core of the solenoid, which short-circuits the booster field. Automatic control can be restored by resetting the trip.

The Middlesbrough Corporation installation controls continuous-current generating plant of 1,300-kw. capacity, including a 600-kw. turbo-generator. The feeder-booster through which this control is effected, can be used as a floating booster in series with the main battery at the station so that an automatic control by means of the Taylor-Scotson device is given, which compares very favourably, in point of efficiency and cost, with other systems of booster-battery regulation. The apparatus has also been applied with success to the problem of rotary-converter regulation, so that the device may be said to have received a thorough testing. The salient points of the gear may be said to be the elimination of sparking at the contact points—a defect common in relay systems; and ease of application to existing plants without undue interruption of supply. The amount of boost which can be given to exciter fields is only limited by their saturation point being reached; and alternators of various types and with different excitations may be regulated simultaneously with one regulator without paralleling the exciters.

Electric Driving of Looms.—An important development of the application of electricity to the textile trade has just occurred in Lancashire. Messrs. Frears, Lord & Brother are building a new weaving shed at Darcy Lever, which is to be electrically equipped throughout, on the system of individual drive. The order for 519 ½ h.p. and 175 ¾ h.p. special loom motors was finally placed with Messrs. Siemens Brothers' Dynamo Works, Ltd. (Caxton House, Westminster). Three-phase current at a periodicity of 50 cycles and a pressure of 200 volts will be supplied by the Lancashire Electric Power Co., who will provide a sub-station for the purpose of transforming their extra high tension supply down to the required pressure. We believe that this is the first individual loom drive of such large size in this country, though it is extensively adopted on the Continent, where the Siemens firm alone have supplied over 13,000 motors for the purpose. The individual driving of looms gives a very considerably increased output, and a much better quality of cloth. The bigger and more complicated the loom is, the better are the results that individual electric driving show. Other advantages accruing are that through the absence of all shafting and belting the light is much better, while in the construction of the shed a large amount of money can be saved. Messrs. Siemens Brothers' Dynamo Works are also supplying the switchboard, and the wiring will be carried out with their material, making use of their well-known "Zed" fuses and distribution boards.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published February 9th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

23,499/09. **Drawn Tungsten Filaments.** BRITISH THOMSON-HOUSTON CO., LTD. (*General Electric Co., U.S.A.*). This specification relates to the mechanical treatment of tungsten whilst hot in order to render it ductile, as described in specifications 21,513/06 and 16,530/07. Pure tungsten powder is compressed into sticks about 8 in. long and $\frac{3}{8}$ in. square, in heated steel moulds. After heating in hydrogen to dispel any impurities, the sticks are sintered so as to become dense and hard by passing an alternating current of about 1,400 amperes through them for several minutes. They are then rolled or worked in a special swaging machine described in the specification, and after repeated and prolonged working the crystalline structure is said to change to a pronounced fibrous structure, so that the sticks are pliable, ductile, and very strong. Drawing is begun when the diameter is reduced to 35 mils, and is continued in successive stages until the diameter is 1 mil or less, as is required. It is found that the tungsten wire can be drawn at ordinary room temperatures after prolonged mechanical working, and the claims of this patent cover this. Three figures.

415/10. **Lamp-shade Collar.** R. J. ESKRIGGE (New Brighton, Chester). A collar for holding the shade on a lamp-holder consists of two pivoted flat rings with a spring urging them into eccentric relation so as to grip the threaded portion of the holder. They are brought into the concentric position by means of two depending tabs. Six figures.

1,164/10. **Lamp-holders, Plugs, &c.** H. E. EVANS (London). This patent covers the provision of separate openings and cord-grips for the two or more flexible conductors entering a lamp-holder, plug, or other device. Five figures.

1,434/10. **Petrol-electric Propulsion.** H. PIEPER (Liége). A system of "multiple-unit" control is described for a train of several vehicles, each with a petrol-electric drive, as covered by specification No. 28,082/09. The controller in use receives the control current from the battery of the vehicle on which it is mounted. Four figures.

1,465/10. **Lamp-shade.** F. D. and R. C. DEWSE (Wilmslow, Cheshire). An arrangement of spring arms is attached to the lamp-holder, and the shade has a collar with an annular groove. The springs enter the groove when the shade is slipped on. To remove the shade it is forcibly pulled off. Three figures.

1,558/10. **Storage Batteries.** E. H. NAYLOR (London). Old plates are renovated or new ones improved by immersing them in a solution of a compound of sulphur and a halogen. After heating, the active material is reduced electrolytically in a bath of dilute sulphuric acid, and then formed in the usual manner. The material expands by this treatment, and fills up vacant spaces.

4,262/10. **Rotary Transformer.** SIEMENS BROS. DYNAMO WORKS and W. PARKER. This specification describes a drum-armature machine with split field poles. The motoring halves alternate with generating halves round the circumference. One figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: ALLGEMEINE ELEKTRICITÄTS-GES., 9,209/10; WESTMINSTER ENGINEERING CO., and WAY [Projector lamps] 9,225/10; SIEMENS SCHUCKERTWERKE-GES. [Searchlights] 14,354/10; BISSON and BERGÈS [Magnetic blow-outs for arc lamps] 28,382/10.

Dynamos, Motors, and Transformers: SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke-Ges.*) [Stator windings for single-phase induction motors] 18,837/10; MASCHINENFABRIK OERLIKON [Regulation of compensated single-phase commutator motor] 23,122/10.

Electric Ignition: DELAGE and WOOG [Electric ignition of gas burners] 11,362/10 and 13,797/10.

Electrometallurgy and Electrochemistry: FULLER and FULLER [Dry cells] 2,300/10; LANGBEIN-PFANHAUSER-WERKE A.-G. [Manufacture of electrolytic iron bars, sheet and wire] 22,204/10.

Heating and Cooking: GRAY [Distributor or switchboard for cooking appliances] 7,882/10; EVERSHED & VIGNOLES, LTD., SCHNEIDER and CLARK [Electric heaters] 10,595/10.

Switchgear, Fuses, and Fittings: BRITISH THOMSON-HOUSTON CO., HASTINGS and WISE [Motor controllers] 29,785/09; ELECTRIC EXPORT WERKE GES. and GOTTSCHALCK [Portable lamp] 29,789/09; PAUL [Terminals] 4,599/10; WEIL [Theatre illumination] 10,043/10; THORNTON (*Clarke*) [Switches] 11,260/10; VON ZWEIGBERGK [Motor controllers] 11,830/10; WALDER [Wall plug and socket for solid walls] 19,433/10.

Telephony and Telegraphy: KEITH [Telephony] 1,420/10; WILSON and WILSON [Oscillation generator for wireless work] 1,649/10; KITSEE [Cable telegraphy] 2,350/10; BISHOP [Locking nuts for telegraph pole insulators] 6,190/10; GALLETTI [Production of continuous wave-trains] 15,497/10; CEREBOTANI and SILBERMANN [Printing telegraph] 16,253/10; FRANCIS [Central battery signalling system] 16,329/10.

Traction: CHAUMERET [Operating tramway points] 24,102/09; MAHONEY [Braking systems for electric vehicles] 15,836/10.

Miscellaneous: LUTH and ROSENS ELEKTRISKA A.-G. [Electrically worked pendulums, bell-ringing devices, &c.] 1,798/10; HAUNZ [Electric clocks] 2,315/10; ELDRED [Platinum-clad metals] 4,466/10; SCHOOP [Coating surfaces with metal, soldering, &c.] 5,712/10; GUNNILL [Advertising signs] 5,773/10; HERBECK and HOLZ [Advertising and signalling apparatus] 19,282/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: JULIUS PINTSCH A.-G. [Lighting plant for railway trains] 996/11; SOC. ALSACIENNE DE CONSTRUCTIONS MÉCANIQUES [Obtaining rapid variation or maintaining constant the voltage of a generator] 1,252/11.

Electrochemistry, &c.: URBAIN, FEIGE and SCAL [Use of metals in the arc employed for sterilisation of liquids] 4,795/10; W. C. HERAEUS GES. and TRENZEN [Electric furnaces] 1,544/11.

Incandescent Lamps: SCHRÖTER [Manufacture of metal filament lamps] 23,121/10.

Opposition to Grant of Patents

23,014/09. **Arc Lamp.** J. NEU. As the result of opposition, this patent has been surrendered. The specification, abstracted in ELECTRICAL ENGINEERING, November 10th, 1910, describes a lamp of the supported carbon type with a pivoted stop which tips up and cuts the lamp out of circuit when the carbons are fully consumed.

27,590/09. **Gyroscopic Mono-rail Apparatus.** R. SCHERL. This patent has been allowed, in spite of opposition, but the Comptroller requires an amendment of the specification. It covers a device to produce forces to act on the gyroscope proportional to the precessional speed.

Restoration of Lapsed Patents

7,526-7/04. **Petrol-Electric Systems.** H. PIEPER. These two patents, which expired due to the non-payment of renewal fees, have been restored to the Société Anon. L'Auto-Mixte. The specifications abstracted in ELECTRICAL ENGINEERING, October 27th, 1910, cover the single controlling lever connected with the throttle of the carburetter and the ignition control lever, and a solenoid for automatically regulating the petrol supply.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Dynamos, &c.: H. LEITNER and R. N. LUCAS [Train-lighting systems] 23,066/02; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [A.C. traction motors] 22,819/04.

Electrometallurgy, &c.: A. F. HARRIS [Apparatus for electro-plating small articles] 24,884/97; J. T. NIBLETT [Primary cell] 23,114/02.

Instruments, &c.: H. P. DAVIS and F. CONRAD [A.-C. induction motor meters] 10,705/98; E. A. REEVES [Prepayment meter mechanism] 23,572/02; F. T. FLETCHER [Speed indicators for automobiles] 23,093/03.

Storage Batteries: C. T. J. OPPERMANN [Active material] 21,362/01; J. T. NIBLETT [Positive element] 23,114/02.

Switchgear, &c.: M. BAUMER [Electromagnetically operated ratchet gear] 21,897/05.

Telephony, &c.: H. T. CEDERGREN [Central battery telephony] 6,485/02; G. GABET [Wireless control of torpedoes] 17,645/05.

Traction: J. JOHNSON [Brakes] 21,581/01; E. DE PASS (*Soc. Anon. des Freins "Stop"*) [Brakes] 23,018/02; R. H. RADFORD [Automatic points] 22,952/03; J. GRESHAM and G. KIERNAN [Vacuum brakes] 22,962/04.

Miscellaneous: G. B. BOWELL and PEARSON FIRE ALARM, LTD. [Fire-alarm system] 23,265/02 and 23,302/03; J. BARR and R. ANDERSON [Portable wood-jointing machine] 23,357/02.

Hosted by Google

LOCAL NOTES

Dover: *Electricity Undertaking.*—An offer by Messrs. Balfour, Beattie & Co., of London, to manage the electricity and tramway undertakings for a term of years has been rejected by the Council. This firm have already reported in what directions they consider the undertakings can be improved, and the Borough Electrical Engineer and Tramways Manager are to be requested to prepare similar reports.

Leicester: *Municipal Wiring.*—A local firm of auctioneers have been instructed to offer for sale the stock of electric fittings and accessories at the Corporation's showrooms. The cost price was £530.

London: *L.C.C. Tramways.*—A meeting of tramway authorities in the Metropolitan Police area is to be held on Friday to discuss steps to be taken for dealing with tramcars that have become disabled whilst running in service.

Bethnal Green: Electric Supply.—A noisy Council meeting took place last week in connection with the proposal to take a supply of electrical energy from the Shoreditch Borough Council. The Electricity Committee presented a report in which it was stated that various objections to the agreement with the Shoreditch Council raised by the London County Council and the Board of Trade had been met. The Shoreditch Council have agreed that any loss to the Bethnal Green Council shall not exceed 5 per cent. for the first three years. It is also proposed that the agreement should be for seven years, but whilst the London County Council regard this as far too short, and considers that 20 or 30 years would be a more economical basis, the Electricity Committee, foreseeing considerable reductions in generating costs in the near future, prefer to have the shorter period in order that they may then secure further competitive prices. There was considerable opposition to the scheme at the meeting, which, according to local newspaper reports, broke up in confusion without any definite decision having been arrived at.

Chelsea: Street Lighting.—A similar dispute to that in Holborn, mentioned on another page, is taking place in Chelsea with regard to street lighting, the Council having resolved to accept an offer of the Gas Light & Coke Co., on a seven years' contract, at a price higher than that tendered by the Chelsea Electricity Supply Co. We shall return to this matter at greater length in our next issue.

Hammersmith: Curtis Turbine.—The Curtis turbine supplied to the Council in 1908 was not quite in accordance with specification, and it was arranged that the contractors should rebuild the alternator portion free of cost and incorporate the latest improvements in order to increase the output of the machine from 1,500 to 2,000 kw., this latter being undertaken at a cost of £550. The reconstruction is now complete, but the machine does not give the additional output. The B. T.-H. Co. have offered to settle the contract by foregoing the extra £550, and the Electricity Committee recommend the adoption of this course.

Maidstone: *Tramways.*—At the last meeting of the Council a resolution that inquiries be made upon what terms the tramway system can be leased for a term of years, was defeated by 11 votes to 3. The matter arose out of a report by the Tramways Manager, showing a further decrease in receipts.

Manchester: *Tramway Employees.*—The Tramways Committee have informed the Tramwaymen's Union that the only terms upon which they will accept arbitration is that the whole case of their working conditions is discussed, including the question of wages.

Newport: *Sales Department.*—The Electricity & Tramways Committee recommend an expenditure of £2,000 upon showrooms and stores for the Electricity Department.

Sheffield: *Street Lighting.*—A proposal to light part of the Attercliffe Road by electricity has been referred back in order that a larger scheme may be considered.

Torquay: *Municipal Showrooms.*—The Electricity Department's new showrooms in Fleet Street were opened last week.

Street Lighting.—A number of 1,000-c.p. metal filament lamps have been installed for street lighting.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Austria-Hungary.—A loan of £10,400 is to be taken up by the municipal authorities at Kralup for an electric generating station, says the *Board of Trade Journal.*

Brighton.—An additional 300-kw. motor-generator set and switchgear is required at Southwick.

Canada.—It is proposed to form a company for the construction of an electric railway from Port Dover to Lake Erie to Simcol, Waterford, Brantford, Paris, and Galt. Addresses to which communications might be sent can be obtained at 73, Basinghall Street, London.

Edinburgh.—Tenders are invited for two water-cooling towers at Dewar Place. (See an advertisement on another page.)

Govan.—The Council require a 500 kw. rotary converter. (See an advertisement on another page.)

Gravesend.—Electrical extensions are contemplated at a cost of £9,000.

London: *Hammersmith.*—A loan of £5,429 is to be taken up for electrical extensions, and an application is to be made for a further loan of £25,253.

Water-tube boilers, superheaters, mechanical stokers, economisers, &c., are required by the Council. (See an advertisement on another page.)

Rathmines.—An inquiry was held last week concerning a loan of £6,000 for electrical extensions.

Roumania.—The *Board of Trade Journal* states that tenders are invited by March 14th for an installation of electric lighting in Tecuci. Address, "Monsieur le Maire, Conseil Municipal," Tecuci.

Uttoxeter.—The Council are considering an electric lighting scheme.

MISCELLANEOUS

Argentine. Thirteen telegraph lines are to be erected in various parts of the Republic, at an estimated cost of £44,000. In connection with the above, cable material to the value of about £17,000 is to be purchased in London, through the Argentine Legation there.

Australia.—The Deputy Postmaster-General, Melbourne, invites tenders by June 14th for the installation at Ballarat of 12 sections of a branching multiple magneto lamp signalling switchboard. The Deputy Postmaster-General, Adelaide, requires tenders by the same date for three sections of a similar board. Copies of specifications, &c., at 72, Victoria Street, or 73, Basinghall Street, London.

Birmingham.—A loan of £32,000 is to be taken up for the completion of Kyott's Lake Road depôt, the reconstruction of a portion of the Bristol Road tramways, and street widenings.

Bournemouth.—A loan of £3,640 is to be taken up for fitting 35 cars with mechanical attachments to the magnetic brakes.

Brighton.—The Tramways Department invite tenders for the overhead and line material, trolley wire, copper bonds, and other materials. Tenders by February 17th.

Dunoon.—There is every prospect of the Council and the promoters of the tramway scheme for this district coming to terms.

Japan.—The British Acting Commercial Attaché at Yokohama reports, says the *Board of Trade Journal,* that a company has been formed for the construction of an electric railway from Hili to Sujiwara, in Kiushiu. The total cost is about £150,000. Particulars of the company in question may be obtained at 73 Basinghall Street, London, E.C.

London: *L.C.C.*—The Highways Committee of the L.C.C. recommend the construction of tramways from Brixton to Herne Hill, at an estimated cost of £28,800.

Marylebone.—Tenders are invited for various electrical stores (see an advertisement on another page).

Nottingham.—A heavy expenditure is contemplated upon track renewals during the next few years.

Portrush.—Three short extensions of the Giant's Causeway electric tramway are to be undertaken.

OSRAM·LAMPS

Hosted by Google

TENDERS RECEIVED AND ACCEPTED

Horsham.—A contract for electricity meters for all sizes, except 5 amps. capacity, has been given to the Electrical Apparatus Co., Ltd.

London: *L.C.C.*—Tenders for the provision of new and the alteration of existing switchgear, and the provision of transformers at the Camberwell, Elephant and Castle, Holborn, New Cross, and Wandsworth sub-stations:—Johnson & Phillips, Ltd., £7,056; Electric Construction Co., Ltd., £7,224; British Westinghouse Co., £7,884 18s.; General Electric Co., Ltd., £7,975; Electric Ordnance and Accessories Co., Ltd., £8,491 10s.; Ferranti, Ltd., £8,639 13s.; A. Reyrolle & Co., Ltd., £8,846. The tender of Messrs. Johnson & Phillips is recommended for acceptance.

The tender of Messrs. G. Munday & Sons at £687 has been accepted for the construction of switch galleries at the Camberwell and New Cross sub-stations.

Hammersmith.—The following tenders have been received for a 3,000-kw. turbo-alternator and condenser:—Willans & Robinson, Ltd., £7,938; Richardsons, Westgarth & Co., Ltd., £7,942; Brush Electrical Engineering Co., Ltd., £8,052; J. Musgrave & Co., Ltd., £8,081; British Westinghouse Co., Ltd., £8,400; J. Howden & Co., Ltd., £8,430; Eicher Wyss & Co., £8,528; C. A. Parsons & Co., Ltd., £8,831; Belliss & Morcom, Ltd., £8,885; Maschinenfabrik Oerlikon, £9,068; Fraser & Chalmers, Ltd., £9,420; British Thomson-Houston Co., Ltd., £9,664; General Electric Co., Ltd., £10,801. The tender of Messrs. Richardsons, Westgarth & Co., which is for an impulse and reaction type of turbine and a Siemens alternator, is recommended for acceptance.

The following tenders have been accepted for 8,180 yards of extra-high-tension cable:—A. Grenier & Co., £2,656; Union Cable Co., Ltd., £2,783; Western Electric Co., Ltd., £2,920; Johnson & Phillips, Ltd., £2,977; British Insulated & Helsby Cables, Ltd., £2,979; Siemens Bros. & Co., Ltd., £2,991 10s.; W. T. Glover & Co., Ltd., £2,999 15s.; Craigpark Electric Cable Co., Ltd., £3,025; W. T. Henley's Telegraph Works Co., Ltd., £3,033; Callender's Cable & Construction Co., Ltd., £3,037 14s.; Standard Cable Manufacturing Co., £3,061; R. R. Todd, £3,081; General Electric Co., Ltd., £3,262. The lowest English tender, viz., that of the Western Electric Co., Ltd., is recommended for acceptance.

APPOINTMENTS AND PERSONAL NOTES

In consequence of the retirement of Mr. J. W. Woods, Senior Assistant Engineer-in-Chief to the General Post Office, owing to the age limit, Mr. A. J. Stubbs is now Senior Assistant Engineer-in-Chief. Mr. W. Slingo has been appointed to fill the vacancy created by Mr. Stubbs' promotion. Mr. Slingo joined the service in 1870, and in 1876, at the Central Telegraph Office, he started the Telegraphy School of Science with five pupils. This school, which was carried on after office hours, was limited to members of the Service, and when it was closed in 1898 there were 850 students. Many of the higher officers in the Engineering, Stores, and other Departments were students in the school. Mr. Slingo was then transferred to the Engineering Department as Technical Officer, taking charge of the secondary battery working, and developing a new system which resulted in great economy and increased efficiency. He also had charge of the Continental communications, and established and developed duplex Hughes working between Germany, Holland, Belgium and France. In 1903 he was appointed Superintending Engineer of the North Wales District, and in September, 1910, was transferred to London to take charge of the work in connection with the inventory now being taken of the National Telephone Company's plant. In his new position he will retain the charge of this work and take over generally the telephone side of the General Post Office. Mr. Slingo has lectured largely throughout the country, and has contributed to most of the technical journals. Mr. Slingo is well-known as the joint author of Slingo and Brooker's "Electrical Engineering for Electric Light and Power Artisans and Students."

In consequence of the above change Mr. E. J. Eldridge and Mr. J. M. G. Trezise, First-class Staff Engineers, and Mr. T. Plumber, Mr. F. Tandy, and Mr. J. Sinnott, Assistant Superintending Engineers, have been appointed Superintending Engineers. We understand that Mr. Eldridge will take charge of the Midland District, Mr. Trezise of the Electric Light Department, Mr. Plumber of the North Wales District, Mr. Tandy of the South-Eastern District, and Mr. Sinnott of the North-Eastern District.

The salary of Mr. A. L. C. Fell, the chief officer of the L.C.C. tramways, is to be increased from £1,750 to £1,875 per annum on April 1st, 1912.

At the Bermondsey Borough Council meeting last week, Mr. C. J. Oake, a son of a member of the Council, was nominated for the appointment of Third Engineer-in-Charge at the Electricity Works, at a salary of £110 per annum. Strong objection was taken to the nomination, and the Committee were instructed to submit three candidates for the appointment.

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £57 12s. 6d. to £57 17s. 6d. per ton (last week, £57 10s. to £57 15s.).

Change of Address.—Mr. Thomas W. How has removed from No. 15 to more commodious offices at No. 17 Victoria Street, S.W.

Simplex Conduits, Ltd.—This firm have purchased the fittings and art metal business of Messrs. Jesson, Birkett & Co., Ltd., of St. Dunstan's Works, Birmingham, at 9 Newman Street, W. The services of Mr. T. Birkett will be retained.

Brimsdown Lamps.—The Imperial Lamp Works (Brimsdown), Ltd., are extending their offices at Kingsway House to about double the present floor space by taking over the whole of an additional suite of rooms.

We have received from Chas. H. Blume (Western Road, Mitcham, Surrey, and The White Building, Sheffield) one of their useful opal glass "slates" for telephone numbers, which the firm are sending out to their friends.

Messrs. Ferranti, Ltd., Hollinwood, Lancashire, have sent us a miniature meter, similar in appearance to one of their well-known house meters, in which the days are metered instead of ampere-hours, as the apparatus is really a calendar.

Callender's Cable & Construction Co., Ltd., have prepared a most effective photogravure plate representing the Thames-built battleship *Thunderer* as she will be when completed for sea. The main electrical distribution on board this ship will be effected by means of Callender's cable and special boxes.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Mather & Platt.—Including £19,879 brought forward, the available balance for 1910, after providing for depreciation, was £129,600. A 10 per cent. dividend, and a bonus of 2 per cent., are recommended on the ordinary shares, carrying forward £37,600.

Bruce Peebles & Co.—After meeting mortgage interest, a loss of £7,275 is shown in the accounts for 1910. All contracts left unfinished by the old company have now been completed satisfactorily.

Metropolitan District Railway Co.—Presiding at the half-yearly meeting last week, Lord George Hamilton said there had been an increase in the number of passengers carried of 7·82 per cent., which constituted a record for the company. It is hoped to increase the number of trains to forty per hour in the near future. Reference was made to the Bill which the Company has in Parliament. (See ELECTRICAL ENGINEERING, Jan. 5th, p. 4.)

London Electric Railway Co.—Lord George Hamilton presided at the half-yearly meeting of this company last week. The revenue from the three companies now represented by the London Electric Railway Company shows an increase of £3,997. The extension of the Bakerloo line from Edgware Road to Paddington is to be undertaken, satisfactory arrangements having been made with the Great Western Railway Company.

SUMMARY

Marconi's Wireless Telegraph Co. have been successful in their action against the British Radio-Telegraph & Telephone Co., in respect of the first of the three patents which are alleged to be infringed. Mr. Justice Parker holds that this patent, covering the use of two circuits in both transmitter and receiver, tuned and linked together by a transformer, is valid and not anticipated by any previous work. He further holds that the defendants' apparatus infringes every essential feature of the patent, and that the substitution of an auto-transformer for a two-coil transformer is of no import, as the latter is not an essential feature of the Marconi patent. (Page 89.)

The Manchester Electricity Committee have replied to the criticisms of the Gas Committee with regard to their policy. They deal at length with the suggested unfair cutting of prices and the inadequacy of the annual contribution from the Electrical Department to the relief of rates. It is also suggested that the Electricity Department should now have a share in the street lighting of Manchester, which has hitherto been the monopoly of the Gas Committee. (Page 89.)

The Chelsea Council have accepted a tender of the Gas Light and Coke Company for street lighting at a price above that offered by the Chelsea Electricity Supply Company. Until the latter entered a protest, they were not allowed to tender at all. (Page 90.)

Mr. L. F. Mountfort read a Paper last week before the Birmingham section of the Institution of Electrical Engineers, on the electrical undertaking of the Birmingham, Tame and Rea District Drainage Board. Centrifugal pumps driven by squirrel-cage induction motors are largely employed, and part of the power is obtained over an overhead transmission line from a destructor station. (Page 90.)

Some new alternating current motor starters are described and illustrated. (Page 92.)

An illustration is given of a lighting fitting for suspension from tramway span wires. (Page 92.)

Particulars are given of an aluminium 3-core cable. (Page 92.)

The Midland Railway Co. have constructed a new electric power station for the supply of current for driving the locomotive, signal, and carriage works, and the lighting of the offices, &c., at Derby. The main generating sets are driven by Willans "disc and drum" turbines, each for an output of 1,250 kw., running at 3,000 r.p.m. Special arrangements are made for obtaining circulating water from the river. (Page 93.)

Our report of the adjourned discussion on high-tension transmission before the Institution of Electrical Engineers appears this week. The discussion is to be further continued to-night. (Page 96.)

In a Paper read before the Manchester Section of the Institution of Electrical Engineers, Messrs. A. P. Fleming and R. Johnson discussed the breakdown of the insulation of high-pressure windings due to chemical action. Ozone and nitric acid formed by brush discharge in cavities destroys most insulating materials, mica excepted. Various methods of obviating the trouble were suggested. (Page 97.)

A letter from Mr. G. Wilkinson, of Harrogate, goes into the causes of the economies obtainable by the use of live steam feed water heaters. (Page 98.)

Mr. A. R. Bennett contributes some observations, in our correspondence page, on the early history of loading telephone lines. (Page 98.)

Demonstrations of electric and gas lighting for railway stations are being made in Birmingham. (Page 98.)

Some notes on the progress of electrical iron and steel furnace work in Scandinavia are given under "Electrometallurgy and Electrochemistry." (Page 99.)

Among the specifications published by the Patent Office on Thursday was one by the British Thomson-Houston Co., for a traction controller, with separate drums for each motor, loosely arranged on a common spindle, so that any one motor can be cut out by fixing

Hosted by Google

the corresponding drum relative to the spindle. G. F. Fuller describes a dry cell, which is sealed up air-tight to prevent evaporation until required for use. (Page 100.)

SOME notes are given in a short article on some Continental and American submarines. (Page 101.)

AN arbitration is taking place in London to determine the price to be paid by the Belfast Corporation for the Cavehill and Whitewell tramways.—The Bethnal Green Council have decided not to take a supply of electricity in bulk from the Shoreditch Council.—An effort is to be made by the Islington Lighting Committee to push shop lighting more vigorously.—At the last meeting of the Marylebone Council, it was stated that nothing has come of the proposal to supply electricity for electrical vehicles at ½d. per unit.—The Board of Trade is to be asked to revoke the powers of the Scarborough Tramways Co. (Page 102.)

A 300 kw. three-phase induction motor is required at Brighton; switchboard extension at Edinburgh; four electrically-driven centrifugal pumps at Calcutta; and cooling tower at Halifax. Electrical stores are required by the Hornsey, Ilford, Bristol, and Acton Councils, and the Great Central Railway Co. Loans are proposed as follows:—Dover (£2,000); Ealing (£20,000); Kettering (£13,100); and Stepney (£3,060). (Page 102.)

THE City of London Electric Lighting Co. recommend a dividend of 7 per cent.; National Telephone Co., 6 per cent. on the deferred shares; London Electric Supply Corporation, 2 per cent.; and the Charing Cross, West End, and City Electricity Supply Co., 5 per cent. The London, Brighton & South Coast Railway Co. have entered into a new contract with the London Electric Supply Corporation for a further 13,000,000 units per annum. (Page 103.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, FEBRUARY 23RD.

South Wales Institute of Engineers.

7 p.m. At Park Place, Cardiff. "Breaking High and Low Potential Circuits," by A. G. Collis.

Institution of Electrical Engineers.

8 p.m. Adjourned Discussion on Long-Distance Power Transmission.

SATURDAY, FEBRUARY 25TH.

Association of Mining Engineers.

2.30 p.m. *Newcastle Branch.* At Milburn House. (1) "Electricity in New South Wales Collieries," by E. K. Scott; (2) "Oils for Transformers and Switches," by G. W. Humphrey; (3) "Considerations Specially Relative to Small Colliery Installations," by T. Thompson.

3.30 p.m. *Notts and Derbyshire Branch.* At University College, Nottingham. (1) "Oil for Transformers and Switches," by G. W. Humphrey; (2) "The Use of a Milli-Ampere Testing Set," by E. E. Beadsmore.

5.30 p.m. *Warwickshire and S. Staffs Branch.* At Imperial Hotel, Birmingham. "Considerations Specially Relative to Small Colliery Installations," by T. Thompson.

TUESDAY, FEBRUARY 28TH.

National Electrical Manufacturers' Association.

2.30 p.m. Annual General Meeting at Institution of Electrical Engineers.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. At University. "Heating Effects in Cables," by C. J. Beaver.

SATURDAY, MARCH 4TH.

Junior Institution of Engineers.

3 p.m. Visit to the L.C.C. generating station, Greenwich.

Annual Dinner of Newcastle Section I.E.E.—The annual dinner of the Newcastle Section of the I.E.E. was held on Thursday. Among those present were Mr. S. Z. de Ferranti, Mr. J. F. C. Snell, Mr. C. H. Merz, Mr. R. B. Morison, and Mr. H. W. Clothier. Mr. Ferranti, in reply to the toast of the Institution of Electrical Engineers, said we were coming to the time when the country was becoming more and more electrical; but notwithstanding all that had been done, it was hard to realise what a very small amount of electrical work had been done in relation to the immense requirements of the future.

[The Gas Department of the Manchester Corporation are complaining that the Electricity Department, who do not contribute to the same extent towards relief of rates, are therefore able to quote low prices for power and are taking away their power consumers. The Electricity Department reply that they have to supply the tramways at cost price and have to make heavier allotments to sinking fund, so that they are equally burdened, and suggest that the Gas Department should no longer have a monopoly of street lighting.]

Reader of "Electrical Engineering":—I wish you boys would not quarrel; there is plenty of sand for both of you, and it doesn't matter where you dig it.

THE WIRELESS TELEGRAPH PATENT CASE

Marconi Patent declared Valid and Injunction Granted

MR. G. MARCONI and Marconi's Wireless Telegraph Co., Ltd., have been successful in their action against the British Radio-Telegraph & Telephone Co., Ltd., in respect of the first and most important of the three patents in question, namely, No. 7,777 of 1900. Mr. Justice Parker gave judgment with regard to this patent on Tuesday, declaring the patent valid, and holding that the defendants' apparatus contained everything of real value in the Marconi patent, and therefore infringed it. Judgment was therefore given for the Marconi Co., subject to appeal, with costs, an injunction against further infringement, and damages. Concise reports of the proceedings at the trial were given in ELECTRICAL ENGINEERING of Dec. 15th and 22nd, 1910, and Jan. 19th last. The actions in respect of the other two patents are to stand over for the present.

Mr. Justice Parker's judgment, the reading of which took over an hour and a half, commenced with a clear summary of the history of wireless telegraphy previous to the date of the patent in question. His lordship stated that though the importance of tuning to obtain selectivity had been well recognised, and Lodge had clearly explained the difficulties met with, no one had succeeded in making a transmitter both a persistent oscillator and a good radiator until Marconi used a closed oscillating circuit inductively coupled to an open aerial circuit by means of a transformer, the two circuits being tuned to one another as described in the 1900 patent. He thought that the effect of the arrangement was perfectly clear, although the object of tuning the circuits was nowhere expressly stated in the specification. It was evident that Marconi desired to make the primary circuit a reservoir of energy and to build up the oscillations in the radiating circuit on the principle of resonance. A transformer had previously been used to step up the pressure in the receiving circuit, and so in this patent Marconi only claimed, in respect of the receiver, the tuning of the two circuits to one another and to the transmitter. The possibility of an accumulative effect depended upon there being loose coupling, as if the circuits were too closely interlinked inductively, the reaction of one upon the other prevented their oscillations being free and independent. He was satisfied that the couplings of the transformers described in the specification were sufficiently loose. The direction to tune contained in the specification premised a direction to couple loosely. He interpreted the patent to cover the substitution of two circuits for one in the case of both transmitter and receiver, the circuits being tuned and linked by a transformer. The utility of the patent was undoubted; it had immediately doubled the distance of communication and had made selectivity practicable under certain conditions.

With regard to the alleged anticipation by Braun, his lordship held that Braun had no intention of tuning at all. The letterpress of the patent contained not the slightest suggestion of the problem dealt with by Marconi, and it appeared that Braun expected the frequency of the oscillations of his primary circuit to be forced upon the secondary circuit, as would result with a very tight coupling. In applying Braun's patent, one would not necessarily arrive at Marconi's arrangement. As to the alleged want of subject-matter, there was no novelty in the use of two circuits in the receiver, but it was new and not obvious to utilise the principle of resonance between these circuits. The adjustment of Tesla coils to get the maximum effect was a different problem altogether; there the tuning was to cure the necessary evil of loose coupling and not to get an accumulative effect. His lordship also dealt in some detail with the earlier patents of Lodge, Thompson, and Tesla, which had been put forward by the defendants as anticipating Marconi, but concluded that none of them gave any indication of the solution of the problem as given by Marconi. He therefore held that the Marconi patent was valid.

Turning to the question of infringement, his lordship held that the defendants' apparatus contained all the essential features of Marconi's patent. It was contended that the coupling used by them between the oscillating and radiating circuits was not a two-circuit transformer, but a one-to-one auto-transformer or an inductive shunt, and that all mutual induction could be eliminated. Further, it was claimed that this one-to-one coreless auto-transformer was new since the date of the patent, and was therefore not an equivalent as regards infringement. His lordship concluded, however, that the name transformer had reference to the effect produced, namely, conversion from electric to magnetic energy and back to electric energy, and though originally applied to a two-coil device, was now rightly applied also to a single winding device, which gave the same effect whether there was a change in pressure or not. The suggestion that there was no conversion and reconversion in the one-to-one auto-transformer in the defendants' apparatus could not be sustained. The experts had agreed that if the working of the device were considered at different instants in the cycle of operations, there were times when the energy in the secondary was the result of induction. In 1900, the substitution of an auto-transformer for a two-coil transformer would not have been subject-matter for a patent. He did not think that the use of a two-coil transformer was an essential feature of the patent, the merit of which was in the idea and not in the means of carrying it out. It did not matter whether one or two coils were used for the inductive link. When a patent was for a combination of parts or a process, and that combination or process produced new and useful results, everyone who produced the same results by using the essential parts of the combination or process was an infringer, even although he had omitted some unessential part or step and substituted another which was equivalent to that omitted. The defendants' apparatus was essentially the same, and therefore infringed.

Mr. J. Hunter Gray asked for costs on the higher scale and for three counsel, but Mr. Justice Parker allowed the latter only. A certificate of validity of the patent was granted, and an order made granting an injunction against the defendants and an inquiry to determine damages. If an appeal is lodged within fourteen days, the injunction will be suspended as relating to infringing apparatus already supplied until judgment has been given in the Appeal Court.

THE MANCHESTER GAS AND ELECTRICITY DEPARTMENTS

ON page 75 of our issue for February 9th we discussed the dispute which has arisen between the Manchester Gas and Electricity Departments. The matter has arisen out of criticisms of the policy of the Electricity Committee. Briefly, these criticisms are: (1) it is alleged that for certain purposes electricity is being sold below cost; (2) that insufficient provision has been and is being made for depreciation; and (3) that the amount paid in relief of rates by the Electricity Department compared with the amount paid by the Gas Department is altogether insufficient.

A very lengthy reply to these criticisms has now been prepared by the Electricity Committee; it outlines the whole history of the Manchester Electricity Department. Incidentally, it is interesting to note that Alderman Gibson, Chairman of the Gas Committee, and the chief critic of the policy of the present Electricity Committee, was Chairman of the Electricity Committee in the early days.

The charge that electricity is being sold below cost applies particularly to power supplies and the supply to tramways, and the Gas Committee have not been able to avoid the common fallacy of assuming that the average costs must represent the cost of each individual supply. The "reply" points out that the costs depend on load factor and that the supply to some consumers necessarily costs less than the average, and to others greater than the average.

As regards depreciation, it is mentioned that the Corporation are under no obligation, legal or prudential, to do more than repay capital within the "lives" of the assets concerned. Legally the obligation ends when the statutory sinking fund has been provided, but voluntarily the Committee have thought fit to supplement this sinking fund by building up a substantial renewals fund. Owing to the delay in starting this latter fund it has been necessary to appropriate all surplus revenue during the past few years. It is pointed out that all the assets acquired up to 1900 have been replaced, and the Department stands as if it were established on that date.

Next comes the question of "unfair" competition, the Gas Committee having put forward a special list of 34 firms who, it was alleged, had previously been customers of the Gas Department, with a turnover of £10,000 per annum, representing a profit of £1,000. The Electricity Committee state that in the majority of cases the Gas Department had already lost the consumers through the installation of private steam generating plants, and through competition by the Electricity Committee, not "by unfair means at cut-throat prices." The words in inverted commas are those employed by Ald. Gibson. No less than thirteen of the firms mentioned have been consumers on the books of the Electricity Department for eleven years, and several do not take any power from the Corporation at all, but have their own generating plants. In another and earlier list of power consumers, although it represents many thousands of horse power obtained by the Electricity Department, less than 100 h.p. were formerly driven by gas. Objection is taken to the claim by the gas interests that details of every contract should be made public, an objection which, it is said, has been supported by the Local Government Board at a Manchester inquiry.

A point against the Gas Committee is that hitherto they

Hosted by Google

have had a monopoly of street lighting, and the suggestion is made that the Electricity Committee should now receive fair consideration in this matter and share in this remunerative business. It is the opinion of the Committee that it is futile to hope that there should be no competition between the two Committees, as this would be a reflection on municipal direction of trading interests. As to the suggestion that a larger sum should be paid to relief of rates, apparently by increasing prices, it is pointed out that the charges for power supply have been passed by the Council, and that the Gas Committee repeatedly overlook the fact that nearly £1,000,000 have been invested in machinery for supplying the tramways, from which no profit is obtained. Further, the general supply to the outdistricts of the Greater Manchester area will for some time to come involve a serious loss, put roughly at £22,000 per annum at present.

STREET LIGHTING IN CHELSEA

Grievances of the Supply Company

THE London Electric Supply Companies certainly have cause for complaint at their treatment by some of the London Borough Councils in the matter of street lighting. Following the curious action of the Works Committee of the Holborn Borough Council, which was discussed in our last issue, comes an instance at Chelsea where the Lighting Committee were prepared to accept an offer from the Gas Light & Coke Co. without even asking for a tender from the Chelsea Electricity Supply Co., and did eventually accept the gas tender, although it was higher than that for electricity.

As we pointed out last week in connection with our article on the Holborn lighting, all the streets in Chelsea are lighted by gas, the contracts for which have about two years to run. Apparently, in order to avoid meeting the competition of electric lighting, which obviously is becoming embarrassing, the Gas Light & Coke Co. offered to forego the period still to expire of the existing contract if the Council would award them a fresh contract for seven years. Quite accidentally the Chelsea Electricity Supply Co. heard that the Lighting Committee had recommended the Council to accept the offer, and an immediate protest brought the message that if the Electricity Company desired to submit a scheme they must do so in six days. No specification was offered, and obviously it was impossible to ascertain the requirements of the Council and to prepare a tender in so short a time. Another protest was therefore made, and the Borough Surveyor informed the company on December 2nd that if they desired to do so, they could submit a scheme for the lighting of the whole of the borough within twelve days. The company immediately set to work, and collected particulars of the present number and situations of the gas lamps, and prepared the details of a complete scheme. The scheme prepared was very similar to that in Marylebone, viz., metal filament lamps in the gas standards; as no specification could be obtained of the illumination or candle-power desired, the company selected lamps of stated wattages, which they thought suitable for adequate lighting of the streets. The price quoted by the Chelsea Electricity Supply Co. was £5,762, whilst that of the Gas Light & Coke Co. was £5,865. It will thus be seen that on a seven years' contract there would have been a considerable saving to the ratepayers by accepting the electric lighting tender.

As a matter of fact, the tenders were only considered by the Lighting Committee about half an hour before the Council meeting on December 21st, so that there could have been no proper deliberation on the matter, and the committee's recommendation that the Gas Company's tender should be accepted was immediately adopted by the Council without discussion. Further, a request by the Chelsea Electricity Supply Co. that one or two streets or portions of streets might be reserved for experimental electric lighting, in order that the Council might obtain some experience and make comparisons with gas-lighted streets, was ignored.

Railway Electrification.—It has been authoritatively announced that the London & North Western and the Great Central Railway Cos. have under consideration the conversion to electric traction of nearly 200 miles of track in the Manchester district.

Central Technical College, Old Students' Association.—The thirteenth annual dinner of this Association was held at the Trocadero Restaurant last Saturday. Mr. W. J. Pope, F.R.S., the President, was in the chair, and the evening was a most successful one. An innovation was introduced in having several small tables instead of one large one, so that students who were at College more or less at the same time were seated together. The speeches were few in number, and an excellent musical programme was provided. Mr. W. Duddell, F.R.S., was elected President for the ensuing year. Old students of the Central who have not yet joined the Association should lose no time in sending in their names to Dr. E. Frankland Armstrong (98 London Road, Reading), the energetic honorary secretary.

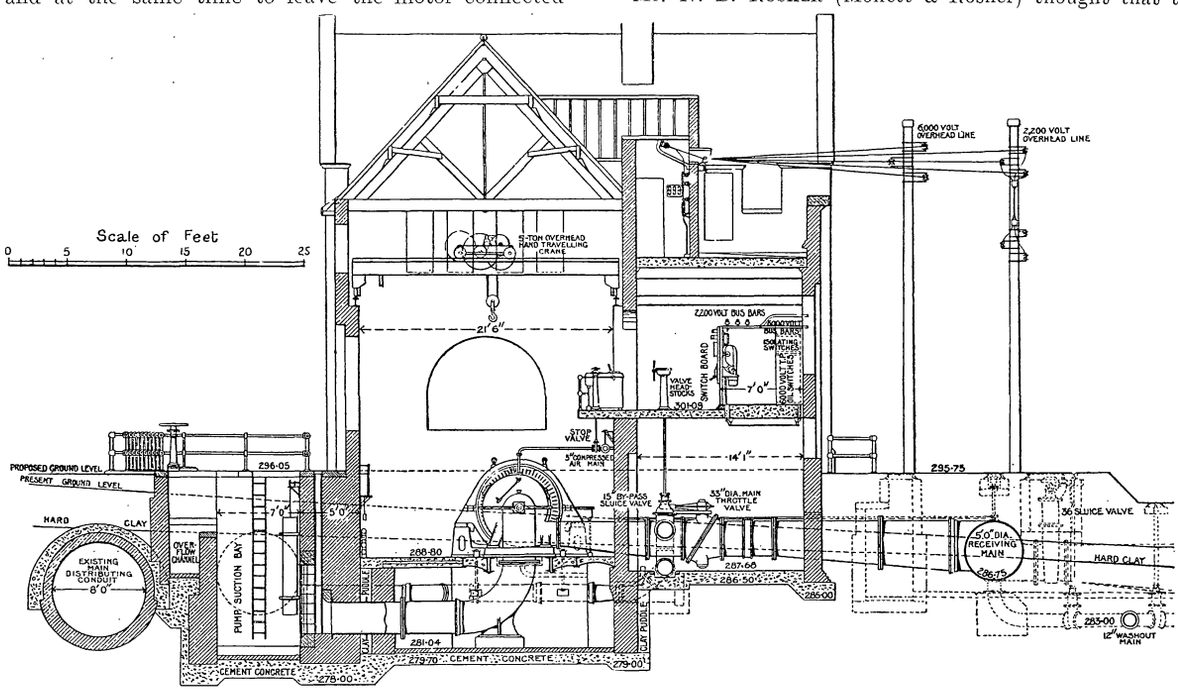
ELECTRIC POWER IN THE BIRMINGHAM DRAINAGE SYSTEM

A PAPER by Mr. L. F. Mountfort, entitled "The Electrical Undertaking of the Birmingham Tame and Rea District Drainage Board," was read before the Birmingham Local Section of the Institution of Electrical Engineers on Wednesday, February 8th. An electrical power distribution system was introduced by the Board in 1905 to replace a group of independent outlying steam pumping plants. Power is derived principally from a destructor station in the Nechells district, and distributed at 2,250 volts three-phase. An additional coal-fired boiler is provided, and two 115-kw. generators are installed. The line is of copper on creosoted wooden poles, except at road crossings, where underground cable is used, and is about 5½ miles long. As a rule, each sub-station contains a transformer in a room adjoining the motor and pumps, and in two cases the low-tension transmission is carried a short distance outside the sub-station for miscellaneous power purposes. The motors connected now aggregate 360 b.h.p., the maximum demand is 150 kw., the load factor 40 per cent., and the diversity factor 2·40 per cent. A standby supply from the Aston Corporation mains is also available, and is sometimes employed on peak loads. The drop in the line is rather large at heavy loads, even reaching 12 per cent., but this does not occur during hours when lighting is required. The cost per unit for power averages 0·875d.

Some notes were given in the Paper on the various processes in sewage disposal to which electric power may be applied, from which it was seen that the incidental power required for various purposes, apart from pumping, may in large works amount to 100 b.h.p., with a fairly good load factor.

The author then passed on to describe in some detail the electrically-driven pumping plant for sewage and storm water at Nechells. When complete this will represent some 1,000 h.p. for lifting the sewage and distributing it over a large area of bacterial filters. The rate of flow varies enormously, but the plant is designed for a maximum of 70,000 gallons per minute. Very heavy peaks are produced by storm conditions, and the annual load factor is as low as 3·5 per cent. Centrifugal pumps are used exclusively. Power is supplied from the Corporation mains at 6,000 volts three-phase through a paper-insulated lead-covered armoured cable, which crosses under the River Tame 3 ft. below its bed. This is connected at a steel terminal pole to an overhead line, 750 yards in length, protected by horn lightning arrestors, and provided with an earth wire. This line runs alongside the 2,250-volt line from the destructor station, and the way they enter the station is seen in the figure which shows the general arrangement of the plant.

The author describes some trouble experienced with the horn arrester, which, when first put in, used to flash over from no apparent reason. They have worked better since 500 ohm graphite resistances were placed in series, and the gaps were shielded by an expanded metal screen from snow.



Of the pumping sets, two are designed for 4,700 gallons per minute, and the three large sets, of which two only are in place, have a capacity of 20,200 gallons per minute. A special pattern of centrifugal pump is used, in which a very flat pressure curve is obtained over the best range of efficiency by making the vanes of the pump disc radial at the outlet edge instead of with a large backward curvature. Thus a variation in pressure of only 15 per cent. is obtained between full and half load. These pumps were made by Messrs. W. H. Allen & Co., of Bedford.

Each pump is direct-coupled to a three-phase squirrel cage, 50-cycle induction motor, with a rating about 33 per cent. above the power required on normal load, to provide for the increased power required in this type of pump with a drop-in head. The smaller motors are designed for 55 b.h.p. at 360 revs. at 2,000 volts, and the larger ones for 225 b.h.p. at 194 r.p.m. on the 6,000-volt circuit. Divided end rings were first tried to improve the starting torque, but afterwards abandoned owing to the current fluctuations caused. The motors are started up by half-voltage tappings from autotransformers. In the case of the motor last installed, a special starter has been employed. This consists of a drum-type switch mounted in a separate tank, and two autotransformers and two choke coils, also in separate oil tanks. The choke coils are inserted between the "starting" and "running" position, so that there is no break in the circuit during the change-over, and are cut out before the running position is fully reached, the whole operation being performed by a single movement of the switch handle.

Hosted by Google

The 2,000-volt bus-bars are in two sections, one set being supplied from the 6,000-volt mains through step-down transformers, and the other set from the Drainage Board power station. When destructor steam is not available the supply is taken from the 6,000-volt feeder, which is also used to help the existing station during times of heavy load, or when steam is low, and no difficulty has been experienced in running the two supplies in parallel. If necessary, one small pumping set can be operated from each supply, without the necessity of running in parallel. The transforming plant consists of three single-phase 100-k.v.a. oil-cooled transformers, with a ratio of 6,000 to 2,200 volts, and one 30-k.v.a. three-phase transformer with a ratio of 2,200 volts to 200 volts.

The 30 twelve-inch sluice valves about the filter beds are all electrically worked from the pumping station, and for this purpose an overhead pole-line has been erected alongside the valves for supplying current to the small driving motors. Each sluice valve has a small ½-h.p. three-phase enclosed motor mounted on a bracket, and operating through spurwheel and worm-gearing, and the time taken to open or shut the valve is about two minutes. Two triple-pole double-throw switches are provided in each motor circuit, one mounted on the station switchboard and the other fixed on the sluice valve, acting as a limit switch to break the circuit when the valve has reached the top or bottom of its travel, and at the same time to leave the motor connected up in the opposite direction when the switch at the station is thrown over. These switches are operated by a travelling nut actuated by the gearing on the valve, and some difficulty was experienced at first in obtaining a suitable switch owing to the two motors being worked in parallel, it being impossible to ensure that both motors should cut out at precisely the same moment.

CROSS SECTION AT NECHELLS PUMPING STATION.

Some figures of costs are given, which work out to a cost per W.H.P. hour of 5·15d., and the paper concludes with some curves of the torque of the motors under starting conditions. It may be mentioned that the main contractors for the generating station were the British Thomson-Houston Co., Ltd., Rugby. For the sewage pumping station, the contractors for the whole of the electrical equipment, with the exception of the 225-h.p. motors, were Messrs. Johnson & Phillips, Ltd. The 225-h.p. motors were supplied by Messrs. Crompton & Co., Ltd.

At the close of the Paper the author described an extraordinary effect on the barbed aerial earth wire; a short circuit occurred on the L.T. windings of a transformer, and the effect of this was made manifest in the aerial earth wire by a number of the barbs, over a length of approximately two feet, being bodily displaced and bunched together. To have allowed of the movement of the barbs the strands of the aerial must presumably have become untwisted, but when discovered the strands appeared as usual.

The discussion was opened by Mr. J. D. WATSON, engineer to the Drainage Board, who gave particulars of the inception of the scheme. Mr. W. J. LARKE (British Thomson-Houston Co.) made some criticisms on the estimates of comparative cost of gas plant *versus* electricity, and remarked on the increasing use of squirrel cage motors instead of the slip ring type. Mr. W. F. MILNES (Birmingham Corporation) also disagreed to some extent with these estimates.

Mr. A. H. MORTON (D. & A. H. Morton) agreed that the whole of the destructor plant should be under one management, in order to get the best results. He considered that in many cases reciprocating engines and pumps were more suitable for pumping sewage than the system described.

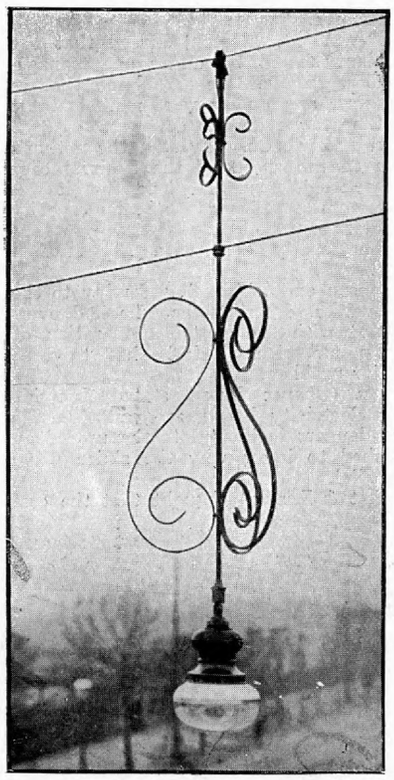
Mr. S. P. SMITH (General Electric Co.) disputed the author's statement that a reduction in the speed of the squirrel cage motors necessarily reduced the efficiency. He held that it was quite unnecessary to instal motors of 33 per cent. greater capacity than the pumps, as the motors can be easily designed so that their overload capacity can readily deal with any unusual demand made on the pump.

Mr. A. L. RAWLINGS (Johnson and Phillips), referring to the electrically operated sluice valves, described how he had overcome difficulties in connection with the electrical operation of a large number of railway points with which he had to deal, and which was a very similar problem.

Mr. A. LINDSAY FORSTER (Chance Bros.) stated that his unbiassed opinion was that electricity had the advantage. He considered that there were dangers incidental to the use of an aerial earth wire. He wished to know why the sluice valve motors were worked in parallel.

Mr. N. B. ROSHER (Moffett & Rosher) thought that the cost of 0·875d. per unit for the destruction plant was decidedly high in view of the fact that steam was provided free; it was about the same as paid for that part of the supply that was bought.

Dr. G. KAPP (Birmingham University) described a drainage installation with which he was connected 15 years ago, and where he installed seven squirrel cage motors having 6 per cent. slip and coupled to water wheels. On receipt of a signal in the power house that water was rising in any one district, the motor in that district would be started by simply dropping the voltage of the generators which fed the motors on that side of the power house and then switching in the required motor. He did not believe in guard wires beneath overhead lines, but preferred an electrically operated relay at the generating station, which would operate when the electrical centre of gravity of the system had been disturbed by a broken live wire coming in contact with the earth. With regard to the statement that the horn type lightning arrester is unsuitable for use at 6,000 volts, owing to the smallness of the gap allowing particles to lodge, a gap of one inch might be used at this pressure if a very thin pointed wire were fixed to one horn and terminated at the correct sparking distance for 6,000 volts from the other horn. On a high pressure surge occurring it will first of all discharge across the fine wire gap, and the small arc set up would enable, so to speak, the main body of the surge to discharge across the wide gap, due to the decreased dielectric strength of the wide gap caused by the discharge across the narrow gap.



Mr. MOUNTFORT, in his reply, defended his figures of costs, and said that the sluice valve motors were worked in parallel in order to reduce the numbers of conductors.

STREET-LIGHTING FITTING

THE accompanying figure illustrates a street lighting fitting introduced by the Wardle Engineering Co., Ltd. (196 Deansgate, Manchester), for suspension from the span-wires between tramway poles. A convenient and effective arrangement is to hang one such fitting on either side of the road midway between the trolley wires and the poles. The lantern is of the well-known "Streetlite" pattern, with a spun-metal case and an aluminium reflector, and can be provided with one or more high candle-power metal filament lamps. The lamps may be wired in series and supplied from the trolley line, or may be connected with the lighting mains if preferred. At Barrow these fittings have been suspended from the ordinary span wires and an additional span wire above, which may support a guard wire. It is found that an effective illumination with a minimum of shadows is produced, and that the fittings are inexpensive to install and not unsightly.

WARDLE SUSPENSION FITTING.

WESTINGHOUSE STARTERS

THE British Westinghouse Electric & Manufacturing Co., Ltd. (Trafford Park, Manchester), have drawn our attention to a line of starters which possess some interesting features. Fig. 1 illustrates a double automatic open-type starter for slip-ring motors, which has been designed to control both the rotor and stator circuits, thus obviating the use of separate main switches. It is provided with automatic overload and no-voltage release, and fully protects the motor against overload and failure of supply on one or all phases. All release coils are in the stator circuit, and do not prevent the use of brush-lifting and short-circuiting gear. Renewable contacts are provided in all sizes. These starters can be used with three-phase motors having two-phase three-wire or three-phase rotor windings; two-phase three-wire motors with rotor windings, as above; or with two-phase four-wire motors with rotors as above. In the latter case, however, it is necessary to take one line of one-phase direct to the motor. The resistances are either of the cast grid or the Westinghouse patent unit type, and are designed to start motors against their full-load torque up to 50 h.p.

For use in fiery mines, textile mills, chemical works, damp situations, &c., the British Westinghouse Co. recommend the use of their oil-immersed starters, as illustrated in Fig. 2. We are informed that the total immersion of all contacts in oil provides perfect protection against the ignition of inflammable gases and explosive dust-laden atmospheres. The mechanism and arrangement of these starters are similar to the above described open pattern, or can be supplied to control the rotor circuit only. Attention is also drawn to an ammeter attachment, which can if required be fitted to all these starters. This provides a ready means of checking the power being used, and indicates at once if the machine is running inefficiently or is being overloaded. Further, it shows the attendant the normal full load, and also, if required, the maximum starting current. He then knows at once when starting up if the machine is not in working order or if he is starting too quickly. The normal full-load current of the machine is indicated in red on the scale.

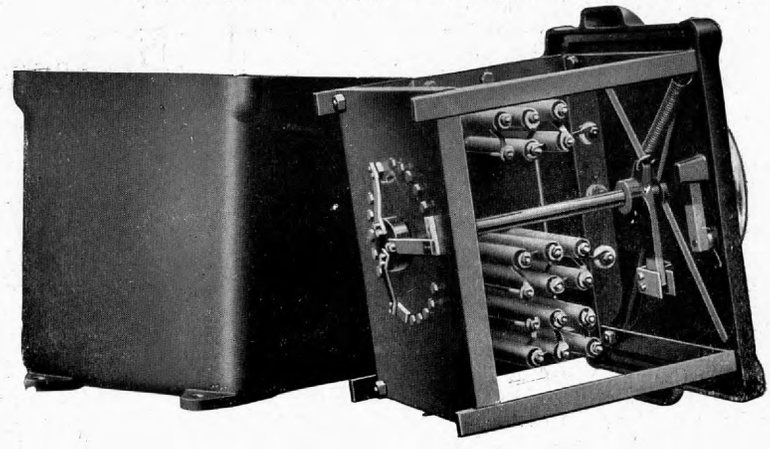

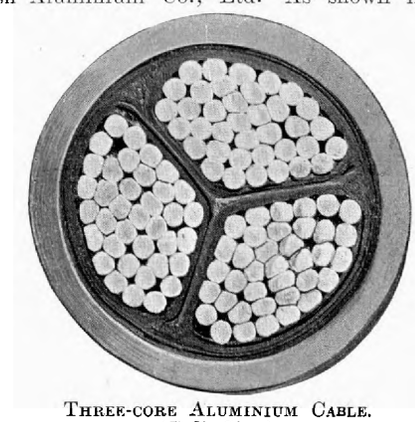

FIG. 2.—OIL-IMMERSED STARTER FOR MINES, &C.

ALUMINIUM 3-CORE CABLE

THE accompanying illustration is from a photograph of a section of a three-core aluminium cable supplied by the British Insulated & Helsby Cables, Ltd., to the order of the British Aluminium Co., Ltd. As shown in the illustration, the cable is paper-insulated, lead-sheathed, served with a covering of jute, and each core consists of 37 wires, 0·118 in. in diameter. The sectional area of conductor is therefore 0·4 sq. in. which is equivalent in conductance to 0·24 copper. It supplies three-phase current at 550 volts across phases to an electrically-driven pump in the works, and is 100 yards in length. We understand from the British Aluminium Co. that the cable was purchased some five weeks ago, when the prices of copper and aluminium were £59 and £72 per ton respectively (corresponding to about 7·6d. and 10d. per lb. of wire), and that the respective prices were £1,090 per mile for the copper cable and £880 per mile for the aluminium cable.

THREE-CORE ALUMINIUM CABLE.

NEW POWER STATION AT THE MIDLAND RAILWAY WORKS, DERBY

FOR some time the small electric power station, which the Midland Railway Co. established at Derby in 1896, has been inadequate for the electrical requirements of the company's large works and offices, and as, on account of lack of both condensing facilities and space, further extensions were impossible, the decision was arrived at last year to put down an entirely new up-to-date steam-driven power station, which would enable the economies of electric driving to be taken advantage of throughout the works. The old station was intended originally for lighting, but later a considerable power load was added. The construction of the new station has been pushed forward with great rapidity. The final decision to proceed was only arrived at in March, 1910, and the work of drawing up specifications was commenced. The first sod was turned on the site on June 26th, and by October 21st last some of the plant was running on load. The old station has now been dismantled.

The site of the power house, separated from the main locomotive works by a canal, and within 200 yards of the river Derwent, is excellent as regards coal and condensing water supply, as well as possibility of extension; its position also has the advantage of being near the centre of gravity of the load. The plant capacity is at present just about 3,000 kw., and power is supplied to the adjoining locomotive and signal works, stores, &c., and is also transmitted at a higher voltage to the carriage and wagon works a short distance away. When the portion of the scheme for converting to electric drive in the works already in hand is complete, the locomotive and signal shops, &c., will require some 1,100 kw., and the carriage works a further 700 kw. The lighting of the general and other offices, &c., accounts for about 200 kw., and doubtless, in course of time, the present gas lighting in the railway station and other parts of the premises will also be supplanted by electric light.

As shown in Fig. 1, the canal between the locomotive works and the power house is spanned by a bridge, which forms a coal- and ash-conveyer, as well as the run for the outgoing feeder cables and the feed water supply pipes. Coal is raised by a bucket elevator from the 20-ton hopper into which it is emptied from the wagons, and taken by a belt-conveyer inside the bridge across the canal, and in a straight line over the coal-bunkers, into which it is distributed by suitable deflecting plates. Separate motors drive the elevator and conveyer, and the whole arrangement is simple and straightforward. The bridge was constructed by the Railway Co., and the conveying plant was manufactured by Messrs. Leech, Goodall & Co. As only fine coal is used, a flat belt can be employed; this is of waterproof canvas, 185 ft. long by 18 in. wide. A 10-ton crab by Messrs. Royce & Co. runs on the bottom flange of the girders, and is now used for the conveyance of ashes. It was, however, of great utility for the transport of machinery, &c., during erection.

The station itself is a brick building consisting of parallel engine and boiler rooms. The boilers are three in number, each of the Stirling Boiler Co.'s five-drum pattern for 20,600 lbs. per hour, 170 lbs. pressure, and are provided with Messrs. Heenan & Froude's "Tester" superheaters, giving 150° F. superheat. Each boiler has 480 3¼ in. tubes, and heating surface of 6,021 sq. ft., and is fired by two automatic stokers by the Underfeed Stoker Co., arranged to burn low-grade "smudge." As regards flues, the three units are entirely independent, and, as shown in Fig. 1, each has its own steel chimney. These are 60 ft. in height and 4·11 ft. internal diameter, lined with firebrick half-way up, and were made in the company's own shops. Forced draught is used, and each boiler has its own Heenan & Froude fan, driven by one of the Midland Railway Co.'s own make of variable-speed motor. The fans each give normally 12,000 cu. ft. of air at 2¼ in. water gauge, but can work up to 15,000 cu. ft. at 2¾ in. The flue gases are sampled continuously by a Simmance-Abady CO_2 recorder. It is intended ultimately to supply a certain amount of steam for heating purposes, &c., in the works. The main steam range consists simply of one header, which can be suitably sectionalised, and the necessary branches direct from the boilers and to the generating sets. It is all of steel with welded flanges and branches, and was supplied by Messrs. Aiton & Co. The valves throughout are of Messrs. Hopkinson's make. Feed water is obtained from a softening plant in the locomotive works, with an alternative town main supply. One steam and one electric feed pump are installed, the former by Messrs. J. P. Hall & Co., and the latter a Rees-Roturbo centrifugal set, driven at 2,250 r.p.m. by a 15-h.p. variable-speed motor. The feed piping is of cast iron in duplicate. A Lea recorder can be used to

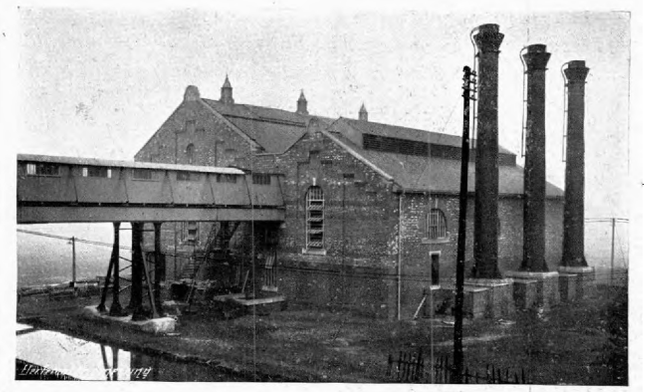

FIG. 1.—VIEW OF POWER-HOUSE SHOWING BRIDGE AND STEEL CHIMNEYS.

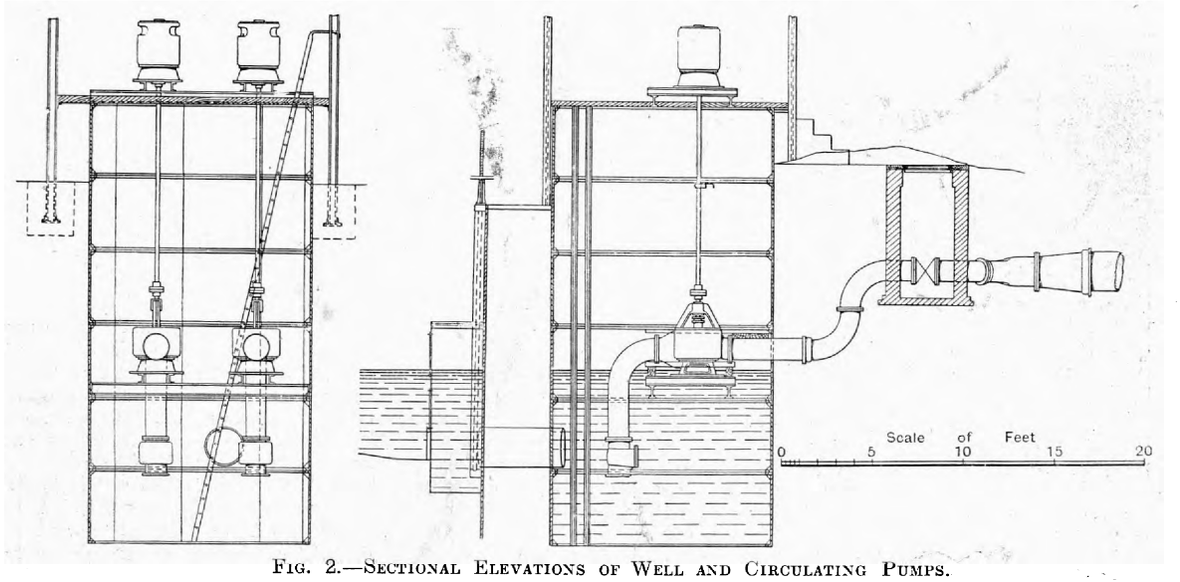

FIG. 2.—SECTIONAL ELEVATIONS OF WELL AND CIRCULATING PUMPS.

measure the flow into the hot well from any or all of the condensers.

Some interest attaches to the condensing water arrangements, which may be described before proceeding to the engine room plant. The condensing water, which, as already stated, is derived from the river Derwent, is pumped up by one of two vertical spindle Rees-Roturbo pumps, each of a capacity of 2,200 gallons per minute, placed in a well alongside the river, and driven by vertical shaft 25-h.p. variable-speed continuous-current motors of the Midland Railway Co.'s own manufacture, running at 400 r.p.m. These motors are controlled entirely from starters in the engine room, to which both main and shunt leads are taken over a pole line. The water is taken through buried pipes 2 ft. in diameter to the condensers, and returned to the river, and the outlet is arranged to be drowned at all levels of the river to maintain the syphon action. Replaceable straining screens are placed in the well, but no special arrangements for reversing the flow in the pipes are provided. A steam ejector removes air from the pipes, and a small pump is also to be installed for this purpose. A section of the well is given in Fig. 2.

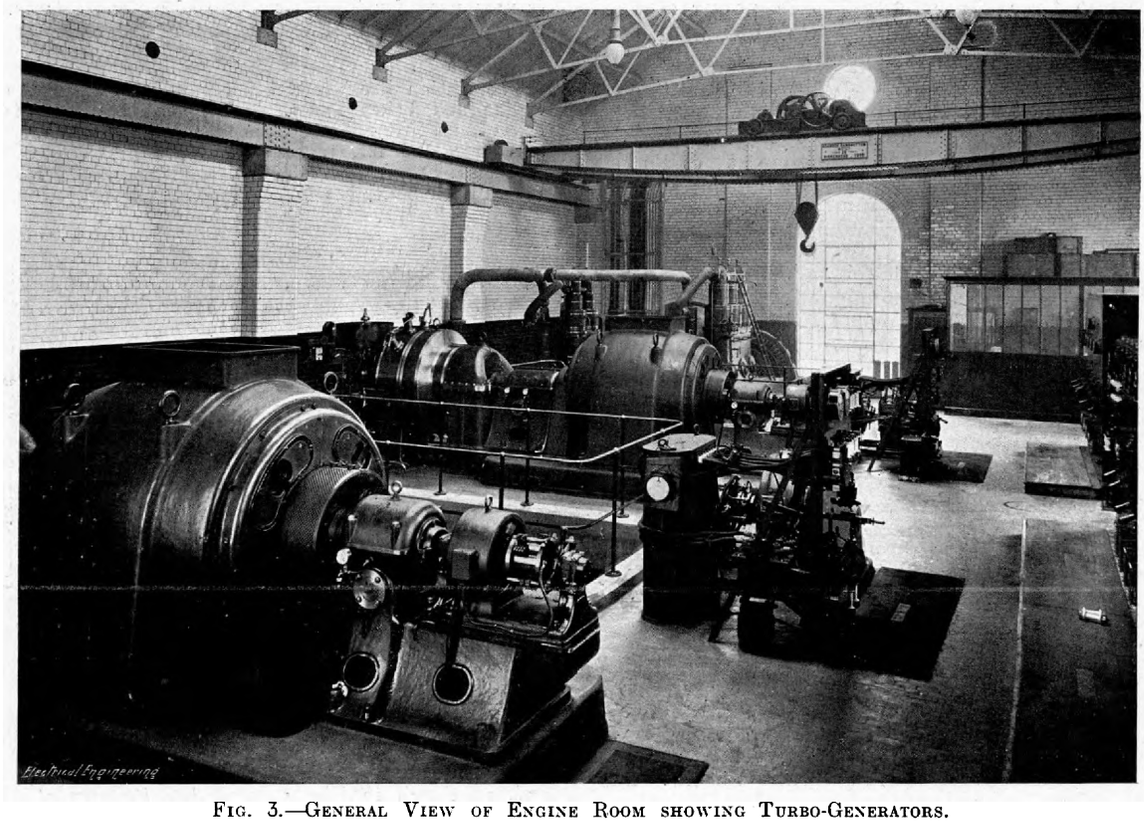

FIG. 3.—GENERAL VIEW OF ENGINE ROOM SHOWING TURBO-GENERATORS.

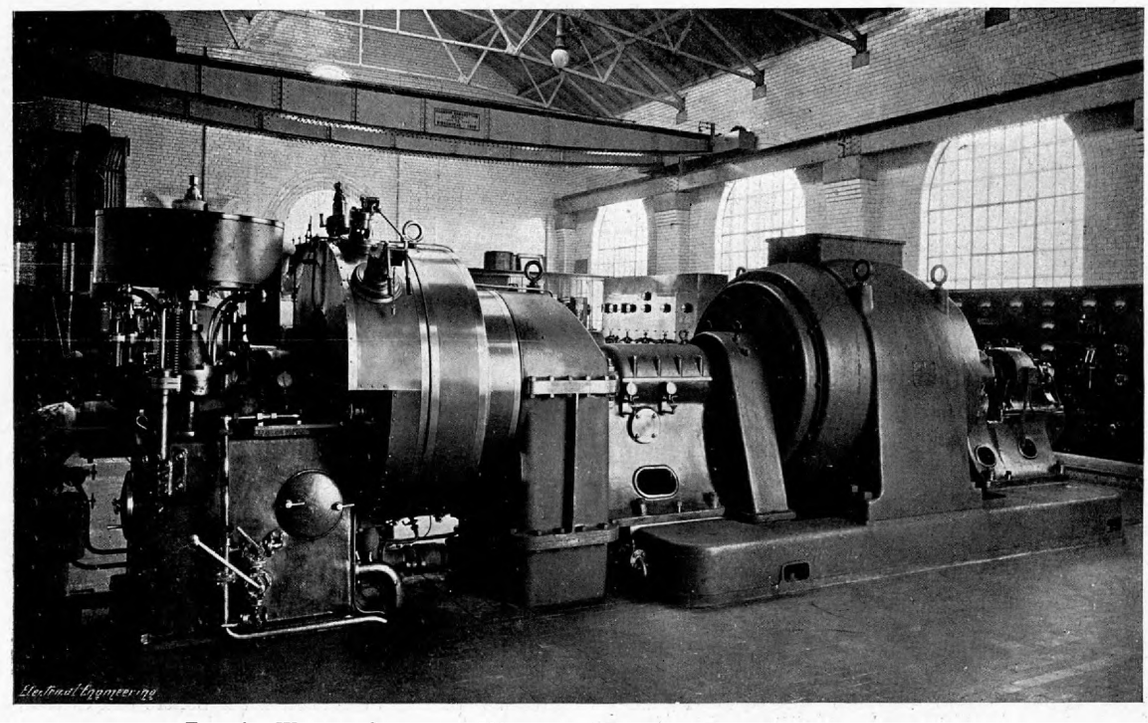

FIG. 4.—WILLANS-SIEMENS 1,500 K.V.A. "DISC AND DRUM" TURBO-ALTERNATOR.

A view of the engine room is seen in Fig. 3. Attention is at once arrested by the compactness of the two main turbo-generating sets, which in spite of their capacity of 1,500 K.V.A. are only 25 ft. in length

Hosted by Google

over all. The turbines are of Messrs. Willans & Robinson's new "Disc and Drum" type, which is much shorter than the purely reaction pattern formerly built by them, and the total size of the sets is further reduced by the fact that they run at as high a speed as 3,000 r.p.m. A view of one of the sets is given in Fig. 4, and a cross section is shown in Fig. 5. The turbines are of interest as being among the first of this type of as large a size to be put to work. In these turbines the steam is first supplied to two impulse rings from the main nozzles, and then passes to five stages of three rows each of Parsons reaction blading. There are altogether 14 nozzles all in the upper half of the case; of these, four are permanently open, three are opened and closed automatically by a steam relay controlled by the difference in steam pressure between the steam pipe and steam chest, and two more sets of three and four respectively can be opened by hand in case of overload. In addition to the ordinary governing, the usual Willans emergency governor is fitted and forced lubrication at 10 lbs. per square inch is supplied to all the bearings. Each set has its own condensing plant with Edwards type air pumps and vacuum augmenters, situated immediately below, and Messrs. Alley & Maclellan's pattern of automatic atmospheric valves are provided for free exhaust in case of failure of the vacuum.

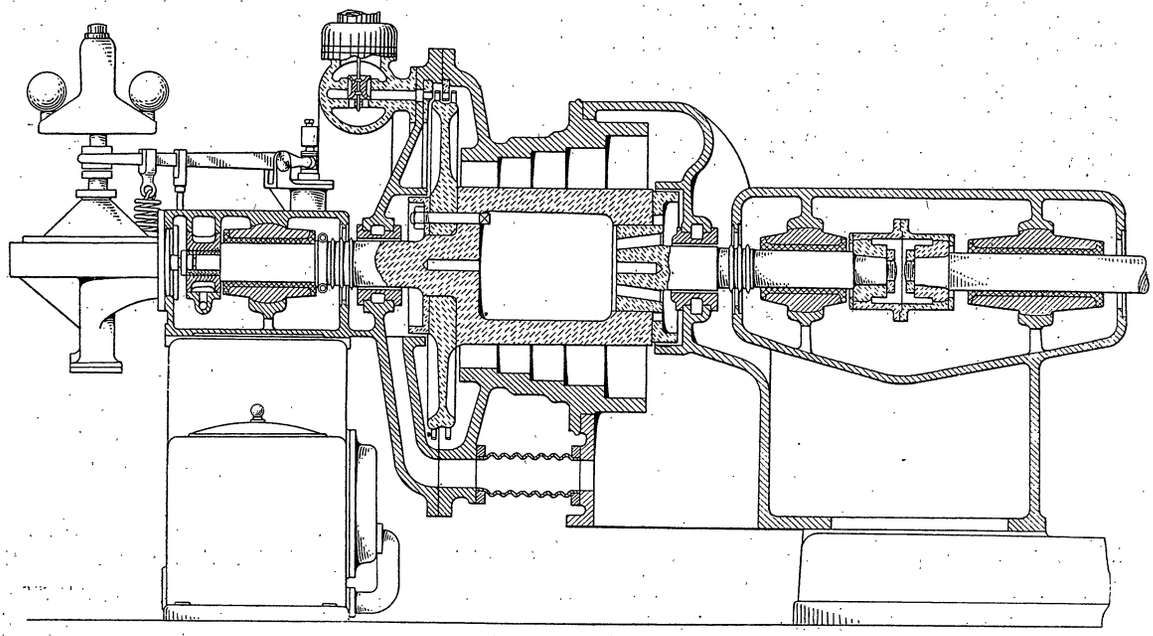

FIG. 5.—CROSS SECTION OF WILLANS "DISC AND DRUM" TURBINE.

The alternators coupled to these turbines are of the latest high-speed pattern of Siemens Brothers Dynamo Works. In view of the high speed they have two-pole rotors. They are of the enclosed self-ventilating pattern, drawing air through ducts from below the floor and expelling it through open chimneys into the engine room. Each machine is rated at 1,250 kw. or 1,500 K.V.A. at 0·8 power factor 460 volts three-phase 50 cycles. Direct coupled interpole 110-volt exciters are provided on each set, and the maximum excitation provided for is 125 amperes. Regulation is by both shunt and series rheostats. The sets have shown good figures for steam consumption on test, especially at medium loads.

Besides these two sets there are two smaller Scott & Mountain alternators of 250 kw. and 160 kw. respectively, driven by Willans reciprocating engines, moved from other stations of the company. These exhaust into a common condenser by Messrs. Story, of Manchester, and are used for light loads. The only other plant in the engine room is a pair of 150-kw. Westinghouse rotary converters, which provide a continuous current supply for cranes, and certain other variable-speed motors in the works and for the station auxiliaries. These are fed through autotransformers placed together with their own switchgear close to the machines (see Fig. 3), and are always started up from the A.C. side by reduced voltage tappings. A fine 15-ton three motor-traveller by Adamson, Ramsbottom & Co. spans the engine room.

The position of the switchgear can also be seen in Fig. 3. The main board is by Messrs. Cowans, Ltd., and is arranged in a straightforward manner, with oil-switches behind the slate panels, and an exceptional amount of light and space at the back of the board. The main generator switches have instantaneous reverse current releases, but the smaller generators are also protected by overload relays with time-elements. Overload relays are provided on the feeder panels, and it should be mentioned that all the trips are worked off the A.C. circuit. Only one set of 'bus-bars is provided. There are in all four generator panels, three transformer panels, for the transmission to the carriage works, four feeder panels, two lighting panels, a testing panel, and a spare panel. The synchronising gear is of Messrs. Everett, Edgecumbe & Co.'s standard pattern, and their instruments are used throughout the board. A very simple leakage-indicating device is employed, consisting of a group of four lamps, one between each phase and earth, and the other shunting a resistance between the neutral point and earth. Inequalities in the glowing of the phase lamps immediately signal on which phase a fault lies, and the excessive current to earth from the neutral causes the fourth lamp to light up brightly. The indications are, however, slightly complicated by the fact that the A.C. and D.C. are connected owing to the use of autotransformers with the rotary converters.

Three Westinghouse 400-K.V.H. transformers in the basement transform up to 6,600 volts for the carriage works feeders, and for the high-tension side a special board, constructed by the Midland Railway Co., but employing Ferranti switches, &c., has been installed. The H.T. gear is in cells behind the board, and three transformer and two feeder-panels are provided. The tripping in this case is D.C. from the circuit of one of the exciters, and change-over switches make connection to whichever one happens to be running.

The transmission to the carriage works is by duplicate feeders, consisting of paper-insulated lead-covered cables supplied by British Insulated & Helsby Cables, Ltd., and a transformer sub-station is provided at the further end. The low-tension distribution at the carriage works is principally overhead. The 440-volt A.C. feeders to the locomotive works, &c., are carried over the bridge and run for the most part over the roofs and high up along the walls of the shops. They, and also the less extensive D.C. cables for the cranes and variable-speed motors, are three-core bitumen-insulated cables, but inside the shops plain braided aerial cables on insulators are used. A part of the D.C. distribution is effected by bare trolley wire. The work of changing over from the old methods to electric driving in the works is being rapidly pushed forward. The Midland Railway Co. have themselves electrical shops of considerable proportions, established originally for repair work, but now build a large number of their own motors. Except for the special cases mentioned above, where D.C. drive has special advantages, induction motors are employed throughout

Hosted by Google

the works, and a combination of group and individual drive is adopted.

The lighting of the offices, stores, &c., is now practically entirely by Osram lamps, and these are run at 2×100 volt networks, supplied by balancing autotransformer, each connected across a 270-volt leg of the star-connected 460-volt circuit, the tappings being arranged so that the neutral is in the centre of the winding, and a certain number of primary turns beyond the outers at both ends. There are three 60-kw. and one 30-kw. transformers at suitable points arranged in this way.

We wish, in conclusion, to record our indebtedness to Mr. H. Fowler, Chief Mechanical Engineer to the Midland Railway, for permission to publish this description, and for putting drawings, photographs, and particulars at our disposal, as well as to Mr. J. Dalziel, who, under Mr. Fowler's direction, designed and supervised the work. We would also express our thanks to both these gentlemen, and to Mr. C. G. Conradi and other of Mr. Dalziel's assistants, for much kind assistance and hospitality on the occasion of our visit to the station.

HIGH-TENSION TRANSMISSION LINES

THE two Papers on this subject by Mr. W. G. Taylor and Messrs. R. Borlase Matthews and C. T. Wilkinson, which were read and discussed at the Institution of Electrical Engineers on January 26th, were further discussed on February 9th. Abstracts of the Papers and a report of the first evening's discussion were given in ELECTRICAL ENGINEERING, February 2nd, p. 57, and the discussions at Newcastle and Manchester were reported in the issue of February 9th. The discussion is to be continued to-night.

Mr. S. G. REDMAN (Merz & McLellan) showed a number of slides of H.T. transmission work carried out in the north-east coast district, where there are at present about 80 miles of 20,000-volt overhead work, and extensions now in hand for a further 50 miles. The first lines put up about six years ago had "A" poles with 40-yard spans, but the spans had since been increased to 80 yards and more. The original practice of having two circuits on one pole had been abandoned, as there were difficulties in screening one line while the other was being worked on. Experience on the north-east coast had shown that an earthed conductor above the line was not a certain safeguard against lightning. He regarded it even as a source of danger, and said that better results had been obtained by placing it below. The standard "A" poles were 40 ft. long and 6 ft. in the ground, the insulators being on a tripod bracket. The earthed wire underneath the conductors sometimes formed the suspension for the lead-covered pilot cables. These had caused some trouble through the lead cracking, but this had now been overcome by avoiding sharp bends. The railway companies insisted upon the same precaution being taken with wires crossing goods lines as for passenger lines. The guard consisted of triangular wooden frames supported by heavy steel cables. In the middle of the span there was an earthed bar which a broken wire was bound to touch. The whole of the lines on the north-east coast were protected with balance gear. On no occasion had they had a wire fall, and although in one or two cases the wires had come away from the fastenings to the insulators, and had touched another wire, they had not broken, and the protective gear had immediately cut out the particular section. The slides included an instance of a 6,000-volt transformer with its switchgear, mounted on a pole for supplying a small village eight miles from Newcastle.

Mr. A. P. TROTTER said that the cost of E.H.T. switchgear at terminal stations was about proportional to the pressure, so that it was rather doubtful if we should have lines in this country long enough to make it worth while running at the high pressures mentioned in the Papers. It seemed probable that we should not go much further than 20,000 volts with ordinary A.C. supply. Somebody had recently stated that Great Britain was behind as regards pressures and lengths of overhead transmissions, due largely to the stringent restrictions of the Board of Trade. This might be so, but he had not come across these restrictions himself. At present there was a limit in pressure for ordinary alternating current overhead work, namely, 250 volts, and anything over that had to comply with certain regulations, be it 2,500, 25,000, or 250,000 volts. In this connection he also drew attention to the fact that Mr. Ferranti twenty-two years ago startled England and the whole of the world with a 10,000 volt system, using a concentric system of mains which had been absolutely safe. Mr. Highfield, a few years ago, had referred to the possibility of a 120,000-volt continuous-current scheme in this country, and he looked forward to the realisation of this with great interest. This hardly indicated that Great Britain was backward in these matters. He did not agree that wooden poles were practically a thing of the past so far as this country was concerned, although it might be so in America, where the process of creosoting was practically unknown, and was almost impracticable on account of the great distances the poles would have to be caried. There seemed to be a great difference of opinion as to the life of wooden poles. This had been put as low as seven or eight years, but in the discussion on Mr. Wade's Paper four years ago, 50 years was given, whilst Major O'Meara put the life at from 30 to 40 years as the average for a well creosoted pole. In certain soils it might be reduced to 15 or 20 years. The Board of Trade regulations did not limit the span between poles, they merely prescribed a factor of safety. There had been a proposal to carry cables across the Tyne with a half-mile span, but the cost of the towers killed it, and a tunnel had to be built. He had also discussed carrying cables across some of the valleys in South Wales, whilst Edmundsons' Electricity Corporation would shortly be carrying high-pressure conductors across Hayle Harbour (Cornwall) with poles 146 ft. high and a 600 ft. span. He wished some engineer would go into the question of flexible poles from a practical point of view. It was necessary to know the stress which was going to be put upon the pole when it was pulled over by the breaking of the line. The clashing of wires together was a point to be reckoned with, and there was also a difficulty of the wires swinging in big waves, which raised the question of the binding of the wire to the insulator. In this country we had been very careful to fix the wires to the insulators so that they could not move at all. In conclusion Mr. Trotter asked whether way-leaves in America, which seemed to be a trouble as they are here, were granted by the Local Authorities for running cables alongside roads, and whether railway companies granted way-leaves to run alongside their tracks, enabling way-leaves on agricultural ground to be avoided?

Mr. J. S. PECK (British Westinghouse Co.) said that cases were only likely to arise where the whole power available at any point could be used within an area, such that the distances would only require pressures up to 200,000 volts. The suspension insulator could no doubt be developed to make 200,000 volts quite possible. The E.H.T. direct-current system was ideal as regards the transmission line, but it was the insulation of the generators and motors which had retarded its development. He did not know of any condenser which could be connected direct to improve the power factor. It was useful to remember in connection with inductance calculations that by doubling the diameter of the wire it was possible to double the spacing with the same inductive drop, and the converse was also true. It would be necessary to use some form of load equaliser for motors as large as 5,000 or 6,000 h.p., connected to a long-distance line. He regarded it as unnecessary to put lightning arresters on the low-tension side of the transformer, because it was possible to insulate the few turns of the winding against any excess pressure. With regard to Mr. Taylor's remarks as to regulation and capacity current of the line, he pointed out that as the capacity current of the line was constant, it would not in itself improve the regulation, which was dependent upon the load. The capacity current might cause the pressure at the receiving end to be higher than at the generating end, however, and it was possible by the use of synchronous machinery at the receiving end to compensate automatically for the fall in pressure with increasing load. He then described a new type of lightning arrester for circuits up to 100,000 volts, consisting of a series of blocks of concrete impregnated with a substance to render them to some extent conducting. Sheets of expanded metal were placed between the succsssive blocks, and were shunted by spark-gaps.

Mr. H. W. CLOTHIER (Messrs. A. Reyrolle & Co.) remarked that five different systems of protection were shown in the diagrams of Mr. Taylor's Paper, and it seemed that breakdowns were regarded as inevitable, but he preferred to so design the switchgear that the faulty part was cut out without causing a cessation in the supply. The balanced system of protection was a far sounder method than any described in the Paper. An earth wire underneath the cables gave a better chance of obtaining sufficient current to earth, in the event of a break, to trip the release. He suggested the possibility of the ground line enclosing the pilot wire.

Mr. W. B. ESSON thought it was quite a misnomer to refer to flexible poles. The primary idea was not to give flexibility but simply to save the cost of materials by having lighter poles specially made to withstand wind pressure at right angles to the line. Aluminium cables, although these were half the weight of copper cables for the same conductivity, were 30 per cent. greater in diameter, and offered greater surface to wind pressure in proportion to the weight. He believed that he had himself originated the rule that the distance between wires should be one foot for every 10,000 volts. It was particularly above 100,000 volts that there was need for star connection to reduce the pressure between the wires and earth. Whilst there might never be any necessity for very high voltages, it should be remembered that it was easier to work lines at 60,000 volts than 30,000 volts, because the surges in the line were proportional to the current and not to the voltage.

Mr. A. A. CAMPBELL SWINTON thought the real limiting factor as regards pressure was the point of brush discharge. One way of increasing the pressure was to use larger wires, such

Hosted by Google

as of aluminium or even iron or steel. The condition of the surface of the wire had an enormous effect in connection with brush discharge. If it were very smooth there was very much less tendency to brush discharge. He would like to know whether these losses increased with time due to the effect of the atmosphere upon the wires. Another method might be to cover the wires with insulating material, but it was doubtful whether solid insulation would really give a better result than the layer of air round the wire.

Dr. M. KLOSS (Siemens Bros. Dynamo Works) said that though there did not seem to be a great demand for high-tension lines in the near future in this country, there was no doubt that many more would shortly be installed abroad. He referred to several long-distance lines carried out by his company. Continental practice was to have spans from 400 to 650 feet, and a maximum stress in copper wire of 22,700 lbs. per square inch. For railway or telegraph line crossings, they attached two auxiliary pieces of wire about 4 feet long to the conductor, and tied all three to separate insulators. For protection against lightning, &c., no overhead aerial wire was used, but the lines were protected at both ends, and sometimes at intermediate points. With regard to corona effect, he thought the loss up to about 115,000 volts was due to the charging current. The corona loss seemed to start at that point, and to be proportional to the pressure above that point.

Mr. B. M. JENKIN (Messrs. Kennedy & Jenkin), on the point of the limiting voltage in this country, called attention to the fact that by doubling the pressure it was possible to transmit twice as much power by only altering the insulators to take the higher pressure, thus practically reducing the cost of the line per kw. transmitted to one-half.

CHEMICAL ACTION IN H.-T. WINDINGS

IN a Paper read before the Manchester Section of the Institution of Electrical Engineers on February 14th, Messrs. A. P. Fleming and R. Johnson described researches into the causes of the chemical action and consequent breakdown in the windings of high-voltage machines. Their investigations show that no case of chemical action has been observed on windings having a lower voltage than about 3,500 to earth; and that such action only occurs where air-pockets are present, and then only when the voltage across them is high enough to produce a discharge. While the action commences on the surfaces of the insulation exposed to air-pockets, the gases produced may be carried beyond the zone where they are formed, and produce action on other portions of the insulation. The action of the products of the discharge—whether these be ozone, oxides of nitrogen, nitrous or nitric acid—on the insulation is most commonly one of oxidation, and the effects produced are as follows: Untreated cellulose materials have their fibrous structure destroyed, and disintegration follows. The oils and gums in insulating varnishes are subjected to super-oxidation and yield organic acids. Linseed oil is most readily affected, but certain asphaltum compounds are attacked only to a limited extent. Mica is itself unaffected, but the cements used in building it up are liable to attack. The authors also find that the production of nitric acid is not essential for deterioration of the insulation to occur, although, when it is produced, the action is greatly accelerated. The final disintegration of varnish-treated materials is greatly accelerated by the action of the released organic acids. Failure due to chemical action is almost invariably the result of a short circuit between turns, and not a breakdown of the slot insulation between windings and frame. The short circuit is caused either by a destruction of the insulation on the conductors, which allows the turns to make actual contact, or by the hygroscopic and therefore conducting matter formed between conductors when nitric acid is present. The authors' experiments showed that unless the air in the cavities of the winding is replenished by "breathing," the chemical action will cease. They also find that when the stress is very high, deterioration other than that due to chemical action may be produced. Thus, if the insulation is made up partly of materials such as mica, of high specific inductive capacity, and partly of material such as paper, of low specific inductive capacity, the insulating value of the latter may be destroyed on the application of a high voltage without the insulation as a whole breaking down, as has been proved before in the case of cables. They conclude that for the range of voltages at present used, failure of machines from chemical action is not to be expected when the average stress across the slot insulation is less than about 35 volts per mil, with any of the methods of winding and insulating commonly employed. A much higher average stress than 35 volts per mil is safe when the size and number of conductors permits the best method of grouping and insulating to be employed, and when the interstices are properly filled with an asphaltum compound. The Paper contains detailed suggestions in this respect. Mica is recommended for use between turns, and the more thorough impregnation of the windings before and after applying the slot insulation is urged. Finally, the authors point out that the green discoloration which frequently occurs on coils treated with linseed oil gum varnishes should not be confused with the chemical action due to high voltage. Such discoloration is quite harmless with the best makes of varnishes.

DISCUSSION.

Mr. C. J. BEAVER (W. T. Glover & Co.) confirmed the authors' views regarding the formation by the action of ozone of super-oxidation products of linseed oil on varnished cambric and cotton coverings. These products were acid, soluble in water, and attacked fabrics and metals. Fabrics impregnated with asphaltum dissolved in a suitable solvent were better than the same fabrics impregnated with the same compound in a molten state, and it would seem better to use varnished fabrics and to keep the maximum stress within limits. Metal foil in the slot insulation connected to one of the conductors to lower the potential gradient should be worth trying. The principle had been used successfully by the speaker's firm for cables from 50,000 to 100,000 volts.

Mr. MILES WALKER (British Westinghouse Co.) described experiments demonstrating that the current flowing through the insulation was partly a capacity and partly a conduction current. The curve representing the power lost per cycle in the insulation showed that the insulation behaved like a number of condensers in series with a number of resistances. The resistance was much decreased as the temperature was raised, and it was necessary to specify the working temperature before the thickness of insulation could be decided upon, as if the heat cannot be dissipated the insulation might heat up and finally break down under a comparatively low stress. This had occurred in the case of several H.T. transformers.

Mr. W. CRAMP (Municipal School of Technology, Manchester) pointed out that the Paper was confined to A.C. machines only, and would require considerable modification to include D.C. machines. He thought that a certain amount of oxides of nitrogen were produced, however weak the discharge. Ozone alone could not produce the effects noticed. It had been found that an extremely unstable compound of nitrogen and oxygen was produced by the electric discharge, and this was a powerful oxidising agent. The presence of moisture considerably accelerated this action. He had found varnishes prepared from paraffin wax very satisfactory, but even paraffin wax became oxidised at very high pressures. It had been shown that the production of ozone was proportional to the frequency, and more trouble was therefore to be expected with high-frequency machines.

Mr. H. D. SYMONDS (British Westinghouse Co.) described a case of breakdown due to destruction of the insulation. The presence of nitric acid was proved in this case. Contrary to the authors, he thought that the action was accelerated by the presence of copper, as a deliquiscent salt is formed as soon as the insulation gets tacky. With regard to the use of a metal sheath round the conductors and on the surfaces of the insulating tubes, he had obtained good results by painting these with an aluminium paint. Test coils which had been running at 6,600 volts for nearly two years showed no signs of destruction of the insulation.

Mr. P. V. HUNTER (Merz & McLellan), in a written communication, described the destruction of a 20,000-volt insulator bolt of Muntz metal enclosed in an insulating tube. The nitric acid fumes generated by the silent discharge penetrated into microscopic cracks in the bolt, and caused these to widen until ultimately the bolt gave way. He preferred one conductor per slot for stator windings whenever this was possible.

Mr. J. S. HIGHFIELD (Chief Electrical Engineer, Metropolitan Electric Supply Co., London) wrote stating that the coils he had used recently for H.T. windings were wholly insulated with mica and a filling compound. Small spaces were left, due to the contraction of the compound on cooling, but these had caused no difficulty. He believed 10,000 volts to earth was the maximum pressure at which it was commercially sound to wind machines, even of large size. Turbo-alternators should not be wound for such high pressures, as in the case of a burn-out the whole winding is destroyed, whereas in slow-speed machines only one or two coils would be damaged. In his opinion the maximum pressure to earth for machines of 3,000 kw. and under should not exceed 5,000 volts.

Mr. H. W. TURNER (Stirling Varnish Co.) suggested that the windings of machines should be treated immediately after a prolonged overload test when the moisture is driven out, with a non-volatile air-drying varnish to fill the interstices, and then be allowed to cool before applying the flash test, as this otherwise caused the formation of nitric acid. He confirmed the author's statement as to the harmlessness of the green discoloration produced on certain varnishes. Proper drying and baking facilities were seldom provided in works, the temperature of the ovens being generally too low or irregular. It was unfortunate that untreated cotton and other cellulose materials were often used. Proper impregnation while hot with non-volatile black varnishes to eliminate cellular air spaces would prevent chemical action.

The authors have submitted a written reply to the discussion.

CORRESPONDENCE

LIVE STEAM FEED WATER HEATING.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—As one who has manufactured and sold large numbers of live steam feed water heaters for boilers during the last few years, which are in use in all parts of the world, I have been much interested in the articles and correspondence which have recently appeared in the technical press arising upon the published results obtained by Prof. Gibson in his researches at the University College, Dundee.

The opinion amongst engineers as to the efficacy of live steam temperature feed water is sharply divided, and a number of correspondents have tried to explain away Prof. Gibson's results by stating that the increased evaporation with steam temperature feed water is due to priming. That this is not so is proved beyond contention by the fact that where superheaters are used it is found that the superheat is higher with live steam feed water in use than where the feed water is used from the economiser direct. If, as the said correspondents have alleged, water were carried over with the steam there would be a drop of temperature in the superheater. Increased superheat is realised in all cases under equal conditions, and this effectively disposes of the contention that live steam heating produces wet steam.

There is another curious result which I have observed on many occasions, *i.e.*, where full steam temperature feed is used there is a decided increase in the temperature of the water from the economiser. The increase may be anything from 10° F. upwards; and this greater activity in the economiser shows that live steam feed water has also a beneficial effect on combustion, probably due to hotter boiler surfaces presented to the flues, which allow the flames to reach further without being damped out by the otherwise cooler surfaces which obtain with the lower temperature feed water.

It is a fact that in many instances years ago the application of live steam feed heaters resulted in failure, but this was due to the want of knowledge as to the conditions which must obtain in order to ensure beneficial results. The comparatively few engineers who have had extended experience in the application of live steam heaters have no difficulty in showing continuously economical results, but they would not think of putting heaters to work under conditions such as have been named, and which have resulted in failure and disappointment.

Yours faithfully,

GEO. WILKINSON.

Harrogate, Feb. 18th, 1911.

LOADING TELEPHONE LINES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Absence from London caused me to miss the discussion on Major O'Meara's Paper on the loading of long telephone lines, but it may not be too late to add a few particulars thereto. I see that doubt exists as to when Mr. Oliver Heaviside's investigations were first translated into practical action. Mr. Heaviside discussed two methods of improving the efficiency of long-distance lines: (1) by leaks (which was not new); (2) by reducing resistance and increasing inductance. The former plan I tested practically in 1888, when erecting the first trunk lines through Fife for the purpose of bringing Dundee and Aberdeen into communication with the Scottish southern systems. The line from Stirling to Dunfermline and thence on to Burntisland was furnished with weatherproof shunt coils at every half-mile, this section being approximately midway between Edinburgh and Glasgow and Dundee. The line spoke quite well over the longest distances which could then be brought into circuit, about 200 miles, roughly, but not appreciably better than it did on a wet day without the shunts. It was, of course, an early observation—anterior to Mr. Heaviside's work—that long lines spoke better in damp than in dry weather, the uniform leakage due to wet insulators being decidedly better than very high insulation, at least for the distances then practised. It chanced that Lord Kelvin, then Sir William Thomson, asked me soon after the coils were fitted if anything had been done in this direction, and was delighted and very much interested on hearing about the Stirling-Dunfermline trunk, about which he made minute inquiries. He then spoke of the inductance theory, mentioning Mr. Oliver Heaviside's name with much appreciation, although I am not sure that the Paper on the subject had then appeared in print. I had, however, previously heard of the theory in some way. Lord Kelvin said that probably a practicable way to apply the inductance method would be to insert coils at intervals along a line. If I am not mistaken, Mr. Heaviside did not himself suggest loading lines with coils till the first volume of "Electromagnetic Theory" appeared in 1893. The copper wire with which the trunks were run provided speaking good enough for existing purposes, and I did not think it worth while, especially in view of the negative results obtained from the shunts, to trouble about inserting coils on any of the lines. But Mr. Heaviside's labours did save the National Telephone Co. a little money on one occasion by preserving in use an iron wire that would otherwise have been scrapped. Selkirk was originally joined to Galashiels by a single No. 11 galvanised iron junction wire about six or seven miles long. When the copper metallic circuit trunks were extended from Edinburgh to Galashiels and Hawick in 1889, it became necessary to turn this into a metallic circuit in order that Selkirk might use the trunks to best advantage. This was done by running a No. 14 copper alongside, and crossing it every half-mile with the iron, so that the loop was half copper and half iron in alternate half-mile lengths. Of course, the iron brought resistance with it as well as inductance, but mixing it with copper enabled it to be used over the longest lengths then available, which a loop composed wholly of No. 11 iron could not have been without notable disadvantage to the speaking. Both this line and the shunted Dunfermline trunk were still at work when I resigned from the National Telephone Co. in 1890. I understand that the foreman, Mr. A. Maclean, who erected the shunts, is still with the company, and will surely recollect them. The Selkirk compromise, I learnt two or three years ago, was well remembered by Mr. C. M. Gardner, who was local manager in the Galashiels District in 1889. The sale of the trunks to the Post Office, where inductance for telephone lines was not then believed in, put a stop to such experiments; but I think I have said enough to show that Heaviside was not, in the early days, ignored entirely by engineers of his own nationality.

I am, sir, yours, &c.,

A. R. BENNETT.

Queen Anne's Chambers, Westminster, S.W.,
February 16th, 1911.

RAILWAY STATION LIGHTING

THE London & North-Western Railway Co. recently invited the electricity and gas departments of the Corporation of Birmingham to submit schemes and to give demonstrations with a view of improving the lighting of the New Street Station. The high-pressure gas system has been installed on one platform, and the electric system on another. This latter has been arranged by Mr. Haydn T. Harrison for Mr. R. A. Chattock (Chief Electrical Engineer to the Birmingham Corporation), and four distinct schemes are shown. Suspended from the roof on one side of the footbridge are seven fittings, each containing three Osram lamps. These are hung at a height of 14 ft. 6 in. above the platform, and suitably spaced to give even lighting. They are controlled by two switches, so that one, two, or three lamps in each fitting may be turned on as required. Besides these, there are four "Excello" flame arc lamps, hung with counterweights so that the height may be adjusted. On the other side of the footbridge are thirteen fittings, each containing three Osram lamps. These are so spaced that a high degree of illumination can be obtained without the aid of arc lamps. These fittings are arranged on two switches, and the wiring is such that alternate lanterns can be switched off. A high degree of illumination on the platform has been aimed at, and special precautions have been taken to avoid glare. The lanterns have special reflectors to equalise the distribution over the platform and to prevent dark patches. All the lamps are hung from the roof. The switching arrangements allow part of the lights to be turned off between train times, or during the night. An official inspection of the electrical installation was made on February 14th. The work has been carried out by Messrs. Reynolds & Bradwell, of Birmingham.

The Institution of Civil Engineers.—The annual conversazione of the Institution has been fixed to take place on Thursday, June 29th, at 8.30 p.m., in the Royal Albert Hall.

The Telephone Service.—In a Paper read before the London Chamber of Commerce on Friday, Mr. H. L. Webb recommended that as an alternative to the acquisition of the whole telephone system of the country by the State at the end of this year, a "Telephone Authority" should be created on the lines of the Port of London Authority, which would take over the telephone plant both of the National Telephone Co. and of the Post Office.

Earthing Resistances for Lightning Arresters.—Difficulties have often arisen on large transmission systems with regard to the choice of suitable resistances for placing between protective spark-gaps and earth, as where the power behind the discharge is considerable, damage is liable to be caused to the resistances. The vessels containing liquid resistances have blown to pieces, and even carborundum rods have been rendered useless by a heavy discharge. To overcome these difficulties, Messrs. Reyrolle & Co. have introduced a special form of resistance in the form of woven asbestos resistance nets immersed in oil in strong cast-iron tanks, provided with suitable porcelain insulated terminals, the resistances for the three phases being contained in the same tank. We understand that these are in very successful use on the north-east coast transmission systems.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

The *Board of Trade Journal* states that H.M. Legation at Stockholm now reports that the experimental furnace established at Domnarfvet with the object of ascertaining whether it was possible, on a commercial basis, to smelt iron ore and produce pig-iron by electricity derived from water-power, has proved a success; at all events the expenses incurred are said to have been made good by the sale of the pig-iron produced, and the experimental furnace has now been replaced by a new furnace on a larger scale. It is proposed to build ten such furnaces, each to use 4,000 h.p.

The Legation at Christiania sends the following particulars with regard to the electric smelting of iron ore in Norway. Of the four principal undertakings in Norway, the Tinfos Paper Mills, near Notodden, in Telemarken, uses a process stated to be the invention of Messrs. Blakstad, Holta & Co., of Skien, and of Mr. Bie-Lorentzen. It is stated that experiments have been conducted since January, 1910, with such success that the directors of the company have decided to erect works for electric smelting in connection with foundries and steel-works, employing up to 15,000 h.p. from a power station now under construction at Hitterdal Lake; 5,000 h.p. is to be available by next summer, and the remainder by 1912. Mr. O. H. Holta, of Skien, is stated to be the promoter of the undertaking, but communications regarding it should be addressed to the Tinfos Papirfabrik, Notodden, Norway.

The "Aktieselskabet Hardanger Elektriske Jern-og Staalverk," at Odda, Hardanger, will employ the Swedish Grönwall method, of which the patent for Norway is held by the Norwegian Electro-Metal Co. Power will be derived from the Tysse Falls. The estimates for the equipment of the works provide for two furnaces of 2,900 h.p., one steel furnace of 800 h.p., and rolling mills with a producing capacity of 6,800 tons of billets. These last, it is calculated, could be delivered at British ports at a price of about £8 per ton. Communications regarding these works should be addressed to the A/S. Norsk Elektrometal, Christiania.

The "Nordenfjeldske Grubecompagni," Trondhjem. This company intends to employ the Lyons method as used at Héroult, California. It is stated that the company intend next spring to erect a furnace similar to the Héroult type, and that considerable iron deposits and waterfalls in the Tromsö district have been acquired. Communications regarding this company should be addressed to Hr. Ingeniör Boholm, Trondhjem.

The Ulefos Ironworks will adopt the methods of the Tinfos Paper Mills and of Mr. Bie-Lorentzen, and also the patents of the Norwegian Electro-Metal Co. Satisfactory trials are said to have been made, and plant for a second electric smelting furnace has been ordered and is expected to be at work shortly. The furnace now being used is supplied with power from the Fehn Mines power station. In future, power is to be derived from a new works which is now approaching completion. The water power of the Eidsfos and the Vrangfos Falls has been acquired for the same purpose, and is being kept in reserve for future extensions. Communications regarding these works should be addressed to Hr. Kammerherre D. Cappelen, Ulefos Jernverk, near Skien.

Arrangements are being made for very complete representation of British chemical and physical apparatus at the forthcoming International Exhibition at Turin, and two actual laboratories are being equipped to show processes at work. The organisation of these exhibits is in the hands of Dr. F. Mollwo Perkin.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

MOTORS AND GEARING.—A pamphlet from the British Thomson-Houston Co., Ltd. (Rugby), gives full details of a series of small motors for continuous current ranging up to 2 h.p. These are of particularly substantial design, and can be arranged as protected, ventilated, or totally enclosed machines. These are provided with laminated poles, and all the refinements of electrical design which distinguish the company's machines of larger size. They are known as type D.A., and are standardised for no less than 16 different voltages ranging from 110 to 530. Another new list deals with the use of worm reduction gears with motors, and illustrates the forms of gear standardised by the company in actual use.

SWITCH FUSES.—Another of the British Thomson-Houston Co.'s new lists deals with porcelain handle switch fuses of a design with several good points to recommend it.

ELECTRIC IRONS.—The British Thomson-Houston Co. have also issued a new list of their "Calorite" flat-irons, which were described and illustrated in ELECTRICAL ENGINEERING, Dec. 8th, p. 777.

CO_2 RECORDERS.—Leaflets have been issued by the Albion Recorders Co. (427 Tower Buildings, Water Street, Liverpool) describing the construction and use of this firm's CO_2 recorder. The simplicity and strong construction are claimed to eliminate the necessity of skilled attention, while the cost of working it is under 1d. per day. The control of the firing provided is claimed to effect a saving of from 5 to 15 per cent. in fuel.

CORONATION ILLUMINATIONS.—A special catalogue of materials, fittings, devices, &c., for Coronation illuminations is being issued by Siemens Brothers Dynamo Works, Ltd. (Incandescent Lamp and Fittings Department, Tyssen Street, Dalston, N.E.). This contains particulars of the company's "Brolite," which has porcelain insulation, aluminium holders, and can be made watertight by rubber sleeves. Various other accessories are listed, together with a fine collection of crystal glass and other devices.

INSULATORS.—A price list from the Sloan Electrical Co., Ltd. (12 Golden Lane, London, E.C.), covers porcelain insulators of all classes, leading-in tubes, cable suspenders, iron brackets, pins, and stay-rods for pole-line work, and a patent wooden plug for fixing insulators in brick or stone. The pamphlet is well arranged; dimensions and prices being given under each item illustrated.

CORONATION ILLUMINATIONS.—An advance copy is to hand from the British Westinghouse Electric & Manufacturing Co. (Supply Department), of a special catalogue of enamelled wood letters and designs, with rows of coloured or frosted lamps, special reflectors, which can be made up into crowns and stars, "Trafford" illumination strip and other accessories for illuminations. Some very effective illustrations of illuminated buildings are also included.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

CORONATION ILLUMINATIONS.—A handsomely illustrated brochure containing a number of night photographs of buildings, garden arches, &c., outlined with "Striplite" and miniature lamps, has been issued by the Electrical Co., Ltd. (122 Charing Cross Road, London). Full particulars and prices of the various patterns of "Striplite" are given, together with various forms of rosette signs and round bulb lamp decoration chains. A one- or two-way mercury flasher for from 1·5 to 24 amperes is also described.

MOTOR CONTROL APPARATUS.—A new catalogue from the British Westinghouse Electric & Manufacturing Co., Ltd. (Trafford Park, Manchester), illustrates a considerable range of motor starting and controlling apparatus, including ordinary lever and multiple switch starters, field regulators, oil-immersed starter, complete motor panels, pillars, and control boxes, as well as drum type controllers and special oil-immersed controllers for mines. The A.C. starting gear is particularly complete, comprising some compact enclosed star-delta switches, complete auto-transformer starters, and the new A.C. starters referred to on another page of this issue. Liquid starters and automatic slip regulators are also included.

We have received from Messrs. John Swain & Son, engravers, a wall calendar decorated with a splendid specimen of their three-colour art reproductions.

Physical Society.—At the meeting of the Physical Society on January 27th, Prof. F. T. Trouton showed a simple apparatus for demonstrating the phase difference between the primary and secondary currents of a transformer. These currents energised two electromagnets with their planes at right angles, and the speed of a copper disc between them showed the torque due to the phase difference between them. The effects of different cores in the transformer were shown. Prof. J. A. Fleming then read a Paper discussing a method of comparing the resistance to high frequency and steady currents of a conductor by a differential air thermometer. Another Paper by the same author, in conjunction with Mr. G. B. Dyke, described an apparatus for measuring the energy losses in condensers traversed by high-frequency oscillations. It was seen that the condenser could be regarded as equivalent to a hypothetical series resistance of a value such that the total resistance is inversely proportional to the square of the current. In a further communication the same author showed some resonance curves with impact and spark ball dischargers. With the spark ball discharger, for close coupling, the resonance curve has three peaks which correspond with the free oscillation period of the secondary and with the two-period oscillations set up by the reaction of the secondary upon the primary circuit. As the coupling is weakened the double-period oscillations die out, and only the free oscillation of the secondary survives. A certain coupling, not far from 10 per cent., gives the maximum current in the secondary circuit in the form of a free oscillation. If the secondary circuit is more highly damped, then the two-period oscillations are more strongly marked, and the maximum free period oscillation has a lesser maximum value. With an impact discharger the double-period oscillations are only apparent when the coupling exceeds about 30 per cent. The curves show how very quickly the primary spark is quenched when using the impact discharger.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published February 16th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

29,785/09. **Traction Controller.** BRITISH THOMSON-HOUSTON Co., H. C. HASTINGS, and W. L. WISE. This is a reversing controller for series-parallel control, and permits of a faulty motor being cut out without interfering with the remaining motors. A separate drum is provided for each motor or group of motors. These are mounted loosely on a common spindle with means for locking them so as to rotate with the spindle. Each drum carries three sets of contacts; one set engages the fingers when the handle is in the "reverse" position, another when the handle is set for forward running, and the third set engages with the fingers in such a manner that the corresponding motor or group of motors is cut out. Thus, to cut out a motor, the corresponding drum is fixed in this position, while the others are free to rotate with the spindle. Four figures.

1,649/10. **Oscillation Apparatus.** PROF. E. WILSON and W. H. WILSON (London). An inductance is connected with a source of current. The primary winding of a transformer and a capacity connected in series are connected directly across the inductance, so that both condenser and inductance receive energy from the source. On disconnecting the source, the energy of the inductance surges into the condenser, and after the first oscillation the condenser and transformer primary winding are short-circuited so that the condenser then discharges directly through the transformer. A rotary commutator to reproduce this cycle of operations is described. The apparatus is stated to be particularly suitable for wireless telegraphy and X-ray work. Nine figures.

2,300/10. **Dry Cells.** G. F., G. J., and L. FULLER (London). Dry cells for hot climates, or to withstand continued storage, are made air-tight to prevent evaporation until the cell is to be used. Another improvement described is the formation of the carbon in the shape of a screw to enable the contact with the manganese block to be improved. Four figures.

4,599/10. **Terminals.** R. W. PAUL (London). A terminal especially suitable for stranded conductors consists of a threaded male portion with an axial slot wide and deep enough to take the largest cable to be clamped. The bottom of the slot is rounded and flush with the shoulder on the base. A nut is screwed over the terminal on to the conductor, and may be locked by passing a pin through the nut and the slot in the terminal. Three figures.

9,209/10. **Arc Lamp Globe.** ALLGEMEINE ELEKTRICITÄTS GES. To prevent the deposit on the inside of the globes of enclosed flame lamps, the upper portion is provided with an air jacket of glass to keep it hot. The fumes are thus condensed only on the lower portion of the globe, where a deposit does not interfere with the light radiation. A device for regulating the air pressure in such a jacket is described. Three figures.

10,595/10. **Heating Apparatus.** EVERSHED & VIGNOLES, LTD., A. SCHNEIDER and W. CLARK. A heating element consists of a resistance wire wound longitudinally or spirally in grooves on a tube of soap-stone or steatite. An envelope of copper entirely surrounds the coil, and has an extension passing up the centre of the core. The insulation between the copper and the wire may be mica, but is preferably air only. The copper envelope is in direct contact with the body or vessel to be heated. Three figures.

28,382/10. **Magnetic Blow-out for Arc Lamps.** A. BISSON and G. BERGÈS (Paris). A blow-out arrangement for flame lamps with converging carbons consists of two core-less coils of different numbers of turns, the individual fields of which interact to produce a horizontal field across the arc. Three figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: BRITISH THOMSON-HOUSTON Co. *(General Electric Co., U.S.A.)* [Electrodes] 17,278/10.

Dynamos, Motors and Transformers: WITTEK [Motor control] 30,262/09; MASCHINENFABRIK OERLIKON [Driving of ring spinning machines] 2,237/10; ELECTRIC CONSTRUCTION Co. and PENSABENE [Control of induction motors] 4,736/10; SIEMENS BROS. DYNAMO WORKS *(Siemens Schuckertwerke Ges.)* [Commutation of frequency converter] 5,479/10; SIEMENS-SCHUCKERTWERKE GES. [Motor control] 14,345/10; FRIED. KRUPP A.-G. [D.C. machines] 25,167/10.

Electric Ignition: CUNNINGHAM [Magneto armatures] 3,802/10; MALSON [Electric blasting fuses] 17,694/10.

Electrometallurgy and Electrochemistry: LAKE *(Fabrik Elektrischer Zünder-Ges.)* [Production of porous electro-deposits] 5,691/10; ANSON, HENDERSON, and EASTICK [Primary cells] 8,996/10.

Heating and Cooking: CUTLER [Liquid heater] 13,864/10.

Incandescent Lamps: BRITISH THOMSON-HOUSTON Co. *(General Electric Co., U.S.A.)* [Manufacture of ductile filaments of refractory metals] 2,759/10.

Instruments and Meters: SPALAZZI [Device for transmitting angular movements to a distance] 2,633/10; BRITISH THOMSON-HOUSTON Co. *(General Electric Co., U.S.A.)* [Measuring instruments] 6,894/10.

Storage Batteries: APOSTOLOFF and DE KARAVODINE [Manufacture of plates] 66/10.

Switchgear, Fuses, and Fittings: BRITISH CONTINENTAL ELECTRICITY Co. *(Brodie)* [Current limiting device] 2,097/10; HERBING [Oil-switch cable box] 2,311/10; ADAMS MANUFACTURING Co. *(Cutler Hammer Mfg. Co., U.S.A.)* [Switches] 2,981/10; POOLEY [Motor starters] 3,068/10; BRITISH THOMSON-HOUSTON Co. and WEDMORE [Leakage indicators for D.C. systems] 6,292/10; STANIAR and CLEGG [Fixing wiring conduit] 6,589/10; LAMB and KELVIN & JAMES WHITE, LTD. [Controlling devices] 7,260/10; DRUSEIDT [Switches] 9,399/10; HOADLEY and TINDALL [Limit switch] 10,654/10; RAUSCH [Switches] 10,799/10; HIRST and COATES [Insulating device for lamp-holder] 13,481/10; DEUTSCHE GASGLÜHLICHT A.-G. (AUERGESELLSCHAFT) [Lamp globe supports] 17,011/10; SCHATTNER [Electrically-operated switches] 22,842/10.

Telephony and Telegraphy: MARTIN [Telephone exchange] 30,458/09; GRAHAM [Telephonic apparatus] 10,965/10; CONNER and PEEL CONNER TELEPHONE WORKS, LTD. [Telephone receivers] 13,177/10; GOLDSTEIN and POOL [Central battery signalling system] 16,330/10.

Traction: CONSOLIDATED BRAKE & ENGINEERING Co. and LUARD [Vacuum brakes] 6,301/10; A.-G. BROWN, BOVERI ET CIE. [Electrically-propelled vehicles] 6,404/10.

Miscellaneous: SHORT [Electromedical apparatus] 2,187/10; SWAN, HUNTER, & WIGHAM RICHARDSON [Minimising oscillatory movements of ships, &c.] 6,878/10; REID and GOOD [Electric clocks] 11,494/10; BRITISH THOMSON-HOUSTON Co. *(General Electric Co., U.S.A.)* [Governors for centrifugal compressors] 12,946/10; SOC. ANON. ATELIERS H. CUENOD [Automatic electric governors] 20,957/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Arc Lamps: SIEMENS-SCHUCKERTWERKE GES. [Search lights] 28,356/10.

Dynamos, &c.: ALLGEMEINE ELEKTRICITÄTS GES. [Polyphase commutator machines] 1,942/11.

Telephony, &c.: SOC. DES TELEGRAPHES MULTIPLEX (SYSTÈME E. MERCADIER) [Mono-telephonic relays] 29,271/10.

Traction: PIEPER [Electrically-driven vehicles] 1,776/11.

Miscellaneous: ADAM [Electric tightening device for cable conveyors] 1,909/11.

The following amended Specification can now be obtained.

BRITISH THOMSON-HOUSTON Co. *(General Electric Co., U.S.A.)* [Electrical propulsion of ships] 19,872/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Dynamos, &c.: A. P. STECKEL [Electric clutch and brake mechanism for rolling-mills, &c.] 23,557/03; C. S. SCHULTZ [Electric reversing mechanism] 23,958/03; BRITISH THOMSON-HOUSTON Co. *(General Electric Co., U.S.A.)* [Control of A.-C. and D.-C. compensated series traction motors] 23,817/04, and [Rotors for turbo-alternators] 22,262/05.

Electric Ignition: H. M. CROUAN [Sparking plug] 25,582/97.

Electrometallurgy, &c.: J. HARGREAVES [Carbon electrodes] 25,519/97.

Instruments, &c.: G. F. MANSBRIDGE [Iron-free variable inductance] 22,206/05; BRITISH THOMSON-HOUSTON Co. and F. HOLDEN [Mercury ampere-hour meter] 22,620/05.

Switchgear, &c.: H. P. DAVIS [Circuit-breakers and fuses] 11,445/99; T. BELL and S. S. BERRY [Tumbler switch] 21,720/99.

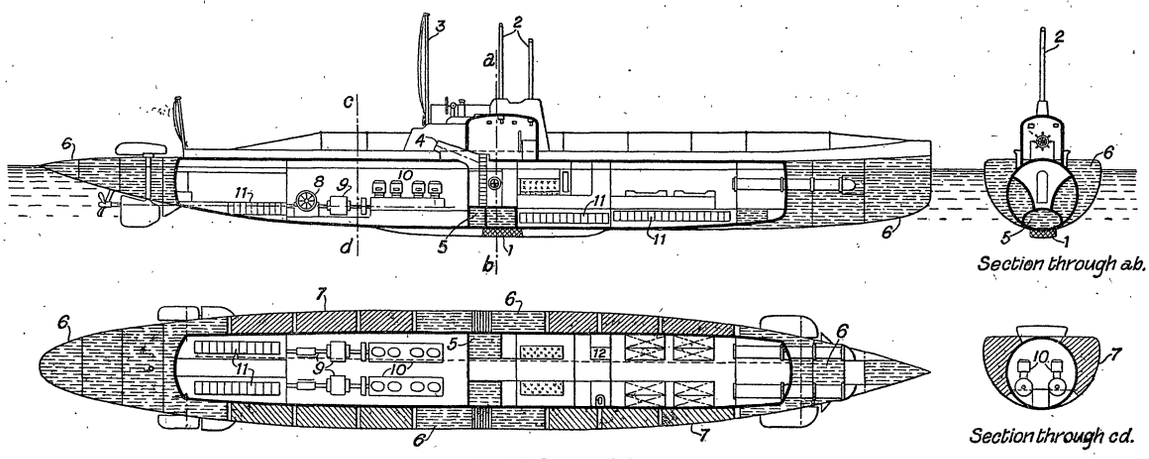
Telephony, &c.: J. STOVER [Signalling apparatus] 19,411/00; D. MURRAY [Perforated tape machines] 21,880/01.

Traction: BRITISH THOMSON-HOUSTON Co. *(W. B. Potter, U.S.A.)* [Electric braking] 21,651/99; BRITISH THOMSON-HOUSTON Co. *(E. A. Sperry, U.S.A.)* [Multiple-unit control] 21,656/99; BRITISH THOMSON-HOUSTON Co. *(C. E. Barry, U.S.A.)* [Multiple-unit control] 21,657/99; W. GRIFFITHS and B. H. BEDELL [Collector for surface-contact system] 21,974/01; A. BROWN and L. W. CROSTA [Rail grinder] 23,796/03; J. F. DINEEN [Surface-contact switch] 22,616/05.

Miscellaneous: J. J. HICKS and G. H. ZEAL [Bell alarm] 25,125/97; H. H. LAKE *(Economic Machine Co., U.S.A.)* [Electrically released stop-motions for printing presses] [illegible]151/02.

Hosted by Google

CONTINENTAL AND AMERICAN SUBMARINES



A FEW particulars of the "Germania" type of submarine built by the Krupp firm at Kiel for the German, Norwegian, Russian, and Austrian navies are given in *Le Génie Civil* (Paris). One of these boats, the *Kobben*, supplied to the Norwegian Navy, is of the following approximate dimensions:—Length, 129 ft.; beam, 12 ft.; draught, 9 ft. 6 ins.; surface displacement, 205 tons; submerged displacement, 255 tons. The hull is double, and the main fuel and water-ballast tanks occupy compartments between the inner and outer shells. The general arrangement of the boat and the position of the oil engines and motors forming the propelling machinery are seen in the figure. The engine-room and a portion of the storage battery are situated aft, the interior adjusting ballast tanks are amidships below the conning tower, with its pressure gauges and periscopes and control apparatus, while the forward part of the boat is devoted to the crew's quarters, the torpedo-room, and the main portion of the battery. The positions of the vertical and horizontal rudders are also shown.

The boat is driven by twin screws with reversing blades by a pair of four-cylinder marine type Diesel engines of 220 h.p. each, using heavy oil fuel, so that the dangers of the highly volatile spirit used in other submarines are avoided. The two electric motors coupled to the shafts are used alone when running submerged, and supplied by the battery. Each is rated at 125 h.p., and the capacity of the battery is 590 kw. hours. The maximum surface speed is 12 knots and the submerged speed is 9 knots. The radius of action at the surface when running at a cruising speed of 9 knots is 1,450 miles, and when submerged it can run 45 miles at 6·5 knots. The ordinary crew numbers six. When running on the surface, the air from the engines is drawn from the engine-room and fresh air enters through pipes. When submerged, an elaborate arrangement of air-cooling and purification is used which permits of the boat remaining under water for 24 hours without inconvenience to the crew. The preparations for diving occupy three to five minutes.

The engine-room also contains various electrically driven pumps, air compressors and fans. The battery spaces are stated to be hermetically sealed. Rapid emptying of the water-ballast tanks can be effected from a reservoir of compressed air kept constantly charged, and increased buoyancy can be obtained in case of accident by detaching a 5-ton keel. An important feature is a telephone equipment, by which communication can be established with a sunken submarine through a cable attached to a buoy which can be released from the interior. The design of the 12 new seagoing submarines which the German Navy will have completed by the end of the year is based on the type we have described.

An account is given in *The Electrical Review* and *Western Electrician* of a trip from Quincy, Mass., to Bermuda and back (about 1,600 miles), made last summer by one of the submarines of the United States Navy, the *Salmon*. It is stated that this record voyage is largely due to her improved electrical equipment, although, naturally, few details are available. The boat is a development of the original Holland type, and is 135 ft. long and of 14 ft. beam. She is a twin-screw craft, propelled on the surface by two 300 h.p. petrol engines, and when submerged by electric motors supplied by storage batteries. Owing to improvements in the electrical equipment, a maximum submerged speed of 12 knots is obtainable, which is stated to be considerably higher than that of any European submarine. The radius of action when submerged has also been increased to 115 nautical miles at an economical speed. There has also been a considerable reduction in the time necessary to change from surface to submerged running conditions, a change which can now be accomplished in three minutes. During speed trials a surface speed of 14 knots has been maintained for 70 hours continuously, but the run to Bermuda was carried out chiefly at a cruising speed of from 6 to 10 knots. Electricity is used for various auxiliary purposes on board, such as for ventilation, working air-compressors, &c., and also for cooking. She has dived to a depth of 200 ft., which is stated to be considerably in excess of the depths accomplished by European submarines.

It may be interesting, for the sake of comparison, to recall the principal data of some of the French "submersibles" which were given in ELECTRICAL ENGINEERING, June 2nd, 1910. The latest boats there described are considerably larger than either of those described above. They displace 800 tons, and are equipped with engines of about 2,000 h.p. Their submerged speed, using only the electric motors, is, however, only 10 knots. The smaller class to which the ill-fated *Pluviôse* belonged displaced 398 tons, and were designed for a submerged speed of 7¾ knots. It is believed that the French Admiralty contemplate the building of submarines of 1,000 tons displacement.

SUBMARINE *Kobben*, SUPPLIED TO THE NORWEGIAN NAVY.

Telegraph Traffic and Movements of Cable Ships.—The Indo-European Telegraph Co.'s lines were down between Odessa and Kertch on the 14th inst., but were repaired on the same day. The cable between Constantinople and Odessa also stopped working on the 14th inst. On the 16th inst. the cable between Lagos and Kotonou was interrupted. The *via* Hanekin, Batoum, and Tao routes were repaired on the same day. The Compagnie Français des Cables Télégraphique has just finished with repairs in the West Indies, but now has to give attention to its section between Australia and New Caledonia, which broke down on the 18th inst. The Eastern & South African Telegraph Co. suffered interruption to their cables between Madagascar and Reunion, and Reunion and Mauritius, on the 19th inst., which isolates the island of Reunion. On the 20th inst. the cable between Lagos and Kotonou was restored. Our last advices *re* the c.s. *Mackay-Bennett* were that she was engaged at Havre on the section running from there to Waterville.

LOCAL NOTES

Belfast: *Cavehill and Whitewell Tramways.*—An arbitration commenced in London on Friday to determine the price to be paid by the Belfast Corporation for the Cavehill and Whitewell Tramways Co. Mr. Lynden Macassey is arbitrator. A few years ago the Corporation decided to purchase these lines at the price of £60,000, but the Bill was rejected in Parliament, as the majority of the ratepayers considered the price excessive. The press are excluded from the inquiry now being held.

Blyth: *Tramways.*—The Ashington Council have asked the Blyth, Newbiggin, Bedlington, and North Seaton Councils to attend a conference, with a view to the promotion of a tramway scheme for the district.

Gravesend: *Tramways.*—It is stated that a private firm has proposed to connect the tramways systems at Dartford and Gravesend, thus making it possible to travel from London to Gravesend by electric car.

Leeds: *Coronation Illumination.*—The City Council is recommended to make a fixed charge of 7s. 6d. to cover the cost of inspecting and connecting Coronation illumination installations. This charge is to include supply of current for a week.

London: *County Council: Tramways.*—At the meeting on Tuesday the proposal to remove the horse tramways in Liverpool Road was referred back. During the course of the discussion the Chairman of the Highways Committee said that the tramway receipts showed a tendency to decline, being now 10·35d. per car mile, against 12·16d. in the early years of the service.

Bethnal Green: Electricity Supply.—After another heated discussion the Council have decided not to enter into an agreement with the Shoreditch Borough Council for a supply of electricity in bulk, but will negotiate with a view to the Shoreditch Council supplying individual consumers in Bethnal Green.

Hampstead: Tramways.—On condition that the L.C.C. withdraws the proposal to construct tramways from Finchley Road to Chalk Farm, from Maida Vale to Upper Avenue Road, and from Marylebone Road to Swiss Cottage, together with the clauses requiring the Hampstead Council to contribute towards the cost of street widenings for the Edgware Road tramways, no opposition is to be made to the other proposed tramways in Hampstead.

Islington: Shop Lighting.—Mr. Albert Gay, the Borough Electrical Engineer, has called the attention of his Committee to the displacement of electric lamps outside shops in the main thoroughfares by gas, and suggests that some action should be taken to meet this competition.

Marylebone: Supply of Electrical Vehicles.—At the last meeting of the Council, Councillor Duncan Watson referred to the recent scheme for supplying energy to electrical vehicles at ½d. per unit as "an impudent advertisement on the part of some of the Council's officials." The Chairman of the Electric Supply Committee stated that nothing had come of the proposal.

Scarborough: *Suspension of Tramways.*—The Corporation have resolved to apply to the Board of Trade for an order determining the powers of the Scarborough Tramways Co., on the ground that the tramways have been discontinued for a period of three calendar months.

Trowbridge: *Electric Lighting.*—A contract has been signed with a Bristol company for the erection of an electric generating station. The company to be formed will be a non-statutory concern, and the agreement provides for the Council's support in the event of a Provisional Order being applied for. In the meantime, the Council give their consent to the breaking up of the roads for the purposes of the undertaking. Further, the Council has the right to purchase at the end of 21 years or every subsequent seven years.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Brighton.—A 300-kw. three-phase induction motor-generator is required (see an advertisement on another page).

Dover.—A loan of £2,000 is to be taken up for plant extensions to supply St. Margaret's Bay district.

Ealing.—An inquiry was held this week concerning a loan of £20,000 for electrical extensions.

Edinburgh.—Tenders are invited by March 7th for switchboard extension. (See an advertisement on another page.)

Halifax.—A water-cooling tower is required for the Electricity Works. Particulars from the Borough Electrical Engineer, and tenders by February 28th.

India.—The Calcutta Electric Supply Corporation, Salisbury House, London Wall, require four electrically driven centrifugal pumps. Specifications from Messrs. Kennedy & Jenkin, 17 Victoria Street, London, S.W.

Kettering.—It is proposed to extend the plant at the power station at an estimated cost of £13,100.

London: *Stepney.*—The Finance Committee of the L.C.C. recommend a loan of £3,060.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

GREATER LONDON.

Tenders are invited for the wiring of the Trade School for Girls, Belvedere Place, S.E. (See an advertisement on another page.)

It is proposed to rebuild and enlarge Gresham College, Basinghall Street.

PROVINCES.

Aberdeen.—Additions to factory of Messrs. G. Mellis & Son, Ltd., in Russell Road. Additions to Engineering Works in Ashgrove Road. Architect, George Watt. New church and hall at Mounthooley.

Belfast.—New hospital, Templemore Avenue.

Edinburgh.—Tenders are invited for the electric lighting of 41, Lauriston Place. Clerk to School Board, Castle Terrace.

Fifeshire.—New school at Wemyss.

Glasgow.—Electric lighting of Cathcart Street School.

Guildford.—The question of electric lighting of the Guardians' premises has been referred to a Committee.

Horsham.—Electric lighting at Workhouse.

Liverpool.—Home for sick nurses at Mill Road Infirmary.

Manchester.—Municipal School in Atherton Street.

North Berwick.—Convalescent Home. Borough Surveyor.

Paisley.—New school in Renfrew Road.

Perth.—New Infirmary.

Plymouth.—Completion of St. George's Church.

Rhondda.—New school at Tylorstown.

Wigan.—Elementary school at Goldborne.

Worksop.—New church.

MISCELLANEOUS

Acton.—Tenders are invited for a twelve months' supply of house fuse-boxes, low-tension cables, lead-covered cables, and steel conduits. Particulars from the Town Clerk, and tenders by February 28th.

Bristol.—Tenders are invited for arc-lamp carbons, globes, joint and fuse boxes, meters, &c. (See an advertisement on another page.)

Great Central Railway Co.—Tenders are invited for various stores, including electric light materials. Particulars from the Stores Superintendent, Gorton, Manchester, and tenders by March 7th.

Hornsey.—The Council require a supply of meters, distribution, joint and fuse boxes, cable, &c. Particulars from the Borough Electrical Engineer, and tenders by March 6th.

Ilford.—Tenders are invited for arc-lamp carbons, cables, incandescent lamps, joint-boxes, and meters. Particulars from the Electrical Engineer, and tenders by February 28th.

London: *Fulham.*—The Council invite tenders by March 1st for a year's supply of electrical stores.

Hackney.—The Electricity Committee recommend the installation of two water-tube boilers, pump, pipework, &c., at an estimated cost of £4,300.

Marylebone.—The date for receiving tenders for stores has been extended until March 15th. Particulars were given in our last issue. (See an advertisement on another page.)

Russia.—The *Board of Trade Journal*, quoting from the "Official Messenger," states that arrangements have been made for the erection of five wireless telegraph stations in 1911, namely, two in the Far East and one each at Reval, Taganrog, and Novorossisk.

A project is under discussion for the construction of an electric tramway forty-six miles long from Moscow to Troitsko-Sergievskiy, at an estimated cost of £918,000.

In the proposed Budget for 1911 a large sum is included for radio-telegraph apparatus.

Nottingham.—The Tramways Committee anticipate an expenditure of £42,906 in the coming financial year on tramway track reconstruction.

Hosted by Google

South Africa.—It is stated that the encouragement given by the Durban Council to domestic uses of electricity has created a demand for electric ovens.

Twickenham.—The Council invite tenders for lighting the whole or a portion of their streets by electricity. Particulars from the Surveyor, Town Hall.

TENDERS RECEIVED AND ACCEPTED

Dublin.—Messrs. Wm. Coates & Sons, Leinster Street, Dublin, have secured the contract for the electric lighting of the whole of the new and old buildings at the Richmond Asylum. Over 2,000 lights are to be installed.

Fleetwood.—The tender of Messrs, Dick, Kerr & Co. for a new balancer booster set at £165 has been accepted.

Grimsby.—The tender of Messrs. J. Beckitt & Co. for the electric lighting of the Municipal Hall, Victoria Street, has been accepted at £24 3s.

Horsham.—A contract has been placed with Messrs. Chamberlain & Hookham, Ltd., for a twelve months' supply of 12-ampere meters.

London: *L.C.C.*—The following tenders were received for the electric lighting of the Wandsworth fire station:—A. Hawkins & Sons, £157 10s.; Malcolm & Allan, Ltd., £174; W. J. Fryer & Co., £190 10s. The lowest tender is recommended for acceptance.

The following tenders have been received for the overhead electrical equipment of the Old Kent Road Stores Depôt:—Johnson & Phillips, £219 17s.; G. E. Taylor & Co., £233 4s.; Clough, Smith & Co., Ltd., £265 9s.; Dick, Kerr & Co., Ltd., £274; and E. Lawrance & Sons, £340. The tender of the first-named is recommended for acceptance.

Hammersmith.—Messrs. Cowans, Ltd., are to supply 20 additional switchboard panels at £16 6s. per panel.

A contract is to be entered into with the Premier Accumulator Co., Ltd., for maintaining the battery at the electricity works at £45 per annum for ten years.

Four transformers are to be hired from the British Electric Transformer Co. for one year in connection with the Shepherd's Bush Exhibition, at the charge of £135.

Wolverhampton.—The tender of the British Electric Transformer Co., Ltd., for two 300-kw. transformers at £456 has been accepted.

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £57 10s. to £57 15s. per ton (last week, £57 12s. 6d. to £57 17s. 6d.).

Bankruptcies.—J. Perkins, 30A Ebrington Street, Plymouth, has been adjudicated bankrupt.

The first meeting of creditors in the bankruptcy of George Barker, electrical engineer, of Leeds and Harrogate, will be held, on March 3rd, at 11 a.m., at the Courts of Justice, Clifford Street, York.

J. W. Barnett, electrical engineer, 25 Waterloo Road, Burslem, trading as Barnett and Hyde, has been adjudicated bankrupt.

A receiving order has been made against George Barker, electrical engineer, Wood Grove, Roundhay, Leeds, and John Street, Harrogate.

A receiving order has been entered against V. G. Burkit, electrical engineer, 38 Park Row, Bristol.

Liquidations.—A meeting of the Contraflo Condenser Co., Ltd., will be held at 3 and 5, Crown Court, Old Broad Street, London, E.C., on March 6th, at 12 noon, to hear the liquidator's account of the winding-up. A similar meeting of the Contraflo Continental Patents Co., Ltd., will be held on the same day at 12.15 p.m.

A meeting of the Yorkshire District Light Railways Syndicate, Ltd., will be held on March 7th, at 4 Central Bank Chambers, Leeds, at 12 noon, to hear the liquidator's account of the winding-up.

Coronation Illuminations.—Siemens Brothers' Dynamo Works, Ltd., remind their friends of the necessity of applying early for designs for special Coronation-illumination schemes. Orders and inquiries can only be dealt with in strict rotation. Although they are prepared to quote for complete schemes, the firm will, in accordance with their usual practice, sublet the actual wiring and erection to contractors to whom they will be pleased to send copies of the new list mentioned in another column.

APPOINTMENTS AND PERSONAL NOTES

After some opposition a proposal to increase the salary of Mr. T. Roles, City Electrical Engineer at Bradford, from £600 to £700 per annum as from April 1st next, with two subsequent yearly increases of £50 each, has been passed by the Corporation.

A solid silver rose-bowl on an ebony plinth has been presented to Alderman F. Larard in appreciation of his many years' connection with the Hull Tramways undertaking.

Mr. H. Ranson, of Falkirk, has been appointed Borough Electrical Engineer at Falkirk at a salary of £200 per annum. Mr. Ranson is at present Assistant Electrical Engineer to the Scottish Electric Power Co., at Falkirk.

Mr. J. W. Oake, Chairman of the Bermondsey Lighting Committee, has resigned. It will be remembered that at the last meeting of the Council Mr. Oake's son was nominated for the post of third engineer-in-charge at the Bermondsey Electricity Works, but the recommendation was referred back.

A charge engineer is required at the Avonmouth sub-station of the Bristol Electricity Department (see an advertisement on another page).

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

City of Buenos Aires Tramways (1904).—A balance dividend of 1s. 3d. per share is recommended for 1910, transferring £3,800 to general amortisation fund, and carrying forward £65.

Dundee & Broughty Ferry Tramways Co.—Interim dividend of 6 per cent. on the preference shares.

Dublin & Lucan Electric Railway Co.—Dividend of 5 per cent. on the preference shares, carrying £521 forward.

City of Buenos Ayres Tramway Co. (1904).—The net revenue for 1910, consisting of annuity payable by the Anglo-Argentine Tramways Co., amounted to £65,865. A dividend of 5s. per share is recommended, transfering £3,800 to General Amortisation Fund, and carrying £65 forward.

Smithfield Markets Electric Supply Co.—There was a net profit of £1,445 15s. for 1910, of which £1,000 are transferred to sinking fund for redemption of debenture stock, and the balance carried forward.

Mansfield & District Tramways.—The net profit for 1910 was £2,483. A dividend of 3 per cent. is recommended, transferring £1,200 to depreciation, and carrying forward £447.

London United Tramways.—The net revenue for 1910, after meeting debenture interest was £30,814, of which £30,000 are transferred to renewals and contingencies fund, and the balance carried forward. The net revenue increased by £7,788. During the year over 3,500 rail joints have been cast welded, practically the whole of the rolling stock has been completely overhauled, and sixty cars have been equipped with covered tops. In addition, new chain-grate stokers have been installed at the power station.

Oxford Electric Co.—Dividend on ordinary shares at the rate of 4¼ per cent. for December half-year, making 7¼ per cent. for the year.

Anglo-Argentine Tramways Co.—The net revenue for 1910 was £65,865, and after paying a dividend of 5s. per share for the year, £3,800 have been transferred to general amortisation fund and £65 carried forward.

Bath Electric Tramways Co.—At the annual meeting last week it was stated that the Company's net revenue had increased by £2,236. It is proposed to issue debentures in order to extend the tramways to Saltford and in other directions.

Dublin United Tramways Co.—Mr. W. M. Murphy presided at the half-yearly meeting in Dublin last week, and specially referred to the question of track renewal, for which no less than £12,000 had been set aside that half-year. He said it was to their interest to maintain the undertaking in as perfect a condition as possible, as in the unlikely event of the local authorities wishing to purchase, the "then value" of the undertaking would be greater than was represented by the capital account of the company, and, moreover, they were entitled to 30 per cent. for goodwill. The large number of accidents on the company's lines was commented upon by one shareholder, but the Chairman replied that, in comparison with other companies, they were not paying excessively for insurance.

Liverpool Overhead Railway Co.—The net balance available for dividends for the December half-year is £11,672, and dividends of 5 per cent. on the preference shares and 1½ per cent. on the ordinary shares are recommended. The number of

OSRAM·LAMPS

Hosted by Google

passengers carried was 5,391,300, compared with 5,215,551 in the corresponding period last year.

Yorkshire (West Riding) Electric Trams.—After meeting all charges, but not declaring any dividend on the ordinary shares for 1910, there is a balance of £2,000.

British Electric Transformer Co.—There was a net profit of £12,187 for 1910, and a dividend of 6 per cent. for the year is declared on the ordinary shares.

City of London Electric Lighting Co.—After placing £45,000 to reserve, and £4,000 to dividend equalisation fund, a dividend at the rate of 7 per cent. per annum is declared upon the ordinary shares, carrying forward £27,000.

National Telephone Co.—There is an available balance of £430,840 14s. for the December half-year, and after meeting the first, second, and third preference share dividend and 6 per cent. per annum on the preferred stock, a dividend of 6 per cent. per annum is recommended on the deferred stock. The sum of £200,000 is to be transferred to reserve and £2,091 carried forward.

London Electric Supply Corporation.—The net balance available for 1910 is £39,272, and a dividend of 2 per cent. is declared upon the ordinary shares, transferring £5,000 to reserve, and carrying forward £3,660. A new contract for the supply of power to the London, Brighton, & South Coast Railway Co. up to 30,000,000 units has been entered into for 14 years, and 14,000 h.p. of additional plant have been ordered.

Northampton Electric Light & Power Co.—A dividend of 6 per cent. has been declared upon the ordinary shares for 1910, carrying forward £1,572.

St. James & Pall Mall Electric Light Co.—At the annual meeting last week it was stated that the agreement with the London Electric Supply Co. to manage the portion of that company's business in the St. James & Pall Mall Co.'s area had worked satisfactorily.

Bournemouth & Poole Electricity Supply Co.—A final dividend at the rate of 6 per cent. per annum for the December half-year, making 5½ per cent. for the year, has been declared.

Kensington & Knightsbridge Electric Lighting Co.—The net revenue for 1910 is £8,875, and a dividend at the rate of 10 per cent. per annum is recommended for the half-year, making 9 per cent. for the year. The balance carried forward is £1,500.

Bastian Meter Co.—The accounts for 1910 allow of a 3¾ per cent. dividend on the ordinary shares, carrying forward £646.

Westminster Electric Supply Co.—After allowing for depreciation, sinking fund, &c., the net balance for 1910 is £40,936. A dividend at the rate of 10 per cent. per annum is recommended on the ordinary shares.

South Metropolitan Electric Light & Power Co.—The net profit for 1910 was £10,546. After meeting the first and second preference dividends, carrying £2,000 to depreciation, and writing £800 off balance of Crystal Palace account, the sum of £1,242 is carried forward.

Charing Cross, West End, & City Electricity Supply Co.—The accounts of the West End undertaking for 1910 show a profit of £19,954, after allowing for the interim dividend on the ordinary shares. A final dividend for the second half of the year, making 5 per cent. for the year, is recommended, carrying forward £9,954, against £5,163 last year. The City undertaking shows a balance of £23,576, after meeting the preference dividend, compared with £13,288 last year.

Underground Electric Railways Company of London.—The accounts for the second half of 1910 shows a surplus of £26,428, and after paying interest at the rate of 1 per cent. on the 6 per cent. income bonds, a balance of £262 is carried forward. Seven of the eight new Parsons' turbines are now working at Lot's Road, and two sets of storage batteries, each of 5,000 ampere hours capacity, and a 1,500 kw. turbo-alternator have been installed during the past six months. The output during the half-year was 66,038,900 units, against 62,500,000 units during the corresponding period of 1909.

NEW COMPANIES

NATIONAL HYDRO-ELECTRIC COMPANY OF MONTREAL.—This company has been formed in Canada with a capital of £250,000.

NORTH LANCASHIRE TRAMWAYS POWER & CONSTRUCTION SYNDICATE: Registered by Milner & Bickford, 10 Moorgate Street, E.C. Capital, £10,000. Constructors of tramways, railways, &c.

LESKOLE & CO.: Palace Works, Enfield. Capital £1,000. Consulting, advisory, or superintending electrical and mechanical engineers.

CARBORUNDUM.—Registered by Treherne, Higgins & Co., 7 Bloomsbury Square, W.C. Capital, £10,000. To adopt agreement with the Carborundum Co. (U.S.A.).

JOHN HIND & SONS, 9 Ulster Chambers, Belfast. Capital, £5,000. To acquire electrical and general engineering business of John Hind, jun.

ELECTRIC HIRING SYNDICATE, Bank Buildings, Kingsway, London. Capital, £1,000. First directors, J. L. Nicholson and R. Borlase Matthews.

CARNET & PEARN.—Registered by Jordan & Sons, 1 Chancery Lane, London, W.C. Capital, £4,000. Electrical engineers and contractors.

PORLOCK & DISTRICT ELECTRIC SUPPLY CO., West Cottage, Porlock. Capital £2,500. Electric supply in Porlock and elsewhere.

Institution of Electrical Engineers: Students' Section.—The annual dinner of the Students' Section was held on Saturday, under the chairmanship of Mr. E. W. Moss, at the Trocadero Restaurant, London, and was most successful. The toast of the Institution was proposed by Mr. A. J. Paterson, vice-chairman of the Students' Section, and was responded to by Mr. S. Z. de Ferranti, President of the Institution. Referring to educational matters, Mr. Ferranti said that there was a tendency to set the standard of knowledge too high, and the standard of application too low. Knowledge was too often obtained to reach the standard and to pass examinations, and the application of it neglected. When anything new was learned, the student should think how to apply the new fact. There were unfortunately many teachers with immense knowledge, but who were bad teachers because they did not appreciate the importance of this application. In proposing the toast of the Students' Section, Mr. W. H. Patchell emphasised the necessity for learning foreign languages and for business training. He also referred to the importance of a sound knowledge of mechanical details. Too many failures of electrical apparatus were due to bad mechanical construction. Mr. E. W. Moss replied, referring to a possible visit of the Students' Section to Norway and Sweden, and asking that the Council of the Institution should have abstracts printed of the students' papers. Prof. S. P. Thompson, replying for the colleges, upheld Mr. Ferranti's views on educational methods, and pointed out how the application of odd facts in science often led to great advances, instancing the case of the peculiarity of erbium in giving a line spectrum, which was applied with such success in the incandescent gas mantle. Responding for the guests, Major O'Meara said that administration in technical questions should be conducted by technical men, and urged the students to aim at becoming administrators.

CROSBY LOCKWOOD & SON'S NEW BOOKS

THREE-PHASE TRANSMISSION. A Practical Treatise on the economic conditions governing the Transmission of Electric Energy by Underground and Overhead Conductors. By WILLIAM BREW, M.I.E.E., late Chief Expert Assistant, Dublin Corporation Electricity Supply. 186 pages, 82 Illustrations. Demy 8vo, **7s. 6d.** net. [*Just published.*

ELECTRIC MOTORS: Their Action, Control, and Application. By FRANCIS B. CROCKER, E.M., Ph.D., M.I.E.E., and MORTON ARENDT, E.E. 297 pages, 158 Illustrations. Medium 8vo, **10s. 6d.** net. [*Just published.*

DYNAMO ELECTRIC MACHINERY: Its Construction, Design, and Operation. By S. SHELDON, H. MASON and E. HAUSMANN. Eighth Edition, completely re-written. Crown 8vo. In Two Volumes. (Sold separately.)

Direct Current Machines. 338 pages. 210 Illustrations, **12/-** net. [*Just published.*

Alternating Current Machines. 366 pages. 236 Illustrations, **12/-** net.

ELECTRICITY IN FACTORIES AND WORKSHOPS: Its Cost and Convenience. A Handbook for Power Producers and Power Users. By A. P. HASLAM, M.I.E.E. 328 pages, 70 Illustrations. Large Crown 8vo, **7s. 6d.** net.

A HANDBOOK OF WIRELESS TELEGRAPHY: Its Theory and Practice. For the use of Electrical Engineers, Students, and Operators. By J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E. Second Edition, revised and enlarged. 381 pages, 187 Illustrations. Demy 8vo, **10s. 6d.** net.

WIRELESS TELEPHONY: in Theory & Practice. By ERNST RUHMER. Translated from the German by J. ERSKINE-MURRAY, D.Sc., M.I.E.E., &c. With an Appendix by the Translator. 238 pages. With numerous Illustrations Demy 8vo, **10s. 6d.** net.

SUMMARY

Our monthly supplement on Electrical Engineering in Mines is included in this issue. It opens with an article giving the main features of the report of the Home Office Committee on Electricity in Mines and the proposed new special rules. Reports are given of the adjourned discussion on Messrs. Dixon & Baxter's Paper before the Institution of Mechanical Engineers, describing the electrical coal hoists at Clydebank, and of a discussion by a branch of the Association of Mining Electrical Engineers on three-phase haulage motors. The verdict of the jury, to the effect that the cause of the Hulton Colliery explosion was not electrical, is announced. Other short articles contain a summary of Electrical Mining Patents for February, and descriptions of a transformer for mining bells and some oil-immersed motor starters.

The whole of the printing machinery employed in the production of the *Illustrated London News* and the *Sketch* has been converted to electric drive. Push-button control with solenoid-operated switchgear is adopted for all the larger machines, and the installation possesses several features of especial interest. (Page 107.)

At a meeting of the Illuminating Engineering Society on Feb. 16th, the subject of school lighting was discussed. Some figures of the cost of school lighting were given by Mr. C. A. Baker, of the London County Council, and figures of illumination in various London schools were given by Mr. J. S. Dow. It was shown that the intensity of lighting in German schools is greater than in England, where the average for desks is about 2 ft.-candles. In Germany about 8 ft.-candles is the average. (Page 108.)

A Paper by the late Mr. J. R. Barr, discussed on February 14th by the Glasgow Section of the Institution of Electrical Engineers, explains the conditions essential to parallel running. The author considered that dampers are unnecessary if the natural period of oscillation of the alternator is greater than 1·4 times the period of the impressed engine impulses. (Page 109.)

The subject of gas *versus* electricity was discussed at a meeting of the Dublin Section of the Institution of Electrical Engineers. Some striking examples of the economy effected by the adoption of electric lighting and power were given. (Page 111.)

A sub-committee of the Works Committee of the Holborn Borough Council have drawn up a new scheme for the lighting of the borough, and propose to invite tenders from both the electric lighting and gas companies. (Page 110.)

Among the specifications published by the Patent Office on Thursday was one by the British Thomson-Houston Co. for a process of manufacturing tungsten filaments. The filaments are drawn down from rods of powdered tungsten which have been sintered at a very high temperature, and then allowed to cool very gradually to render them ductile.—Apparatus for the automatic acceleration, switching off, and braking of traction motors according to a predetermined speed-

Hosted by Google

distance curve is described by W. Wittek.—A patent for a belt for train-lighting dynamos expires on Saturday after the full life of fourteen years. (Page 112.)

AT the meeting of the National Telephone Co. last week it was stated that certain differences have arisen between the company and the Postmaster-General which may necessitate arbitration. The company have hopes, however, that arbitration will not be necessary in regard to the valuation of the greater portion of their undertaking. (Page 113.)

THE provisional programme of the convention of the Incorporated Municipal Electrical Association, to be held at Brighton in June, has been issued. (Page 112.)

THE annual dinner of the Manchester Local Section of the Institution of Electrical Engineers was held last week. (Page 113.)

THE Hendon Council have decided to take over the trolley omnibus system which has been running experimentally.—Swansea Corporation contemplate purchasing the local tramways undertaking.—Mr. Stephen Sellon puts the value of the Cavehill and Whitewell tramways at £37,357, and Mr. H. A. Cutler, the Belfast City Surveyor, at £19,371. Arbitration for the purchase of the line is still proceeding.—Halifax Tramways Committee intend to call the attention of the Municipal Tramways Association to the objectionable Standing Order 22.—Mr. Bromley Holmes, Consulting Engineer to the Liverpool Corporation, is in favour of extending the rateable value system of charging.—The adoption of Edison battery tramcars is contemplated in Melbourne. (Page 113.)

A 1,000-KW. turbo-generator is required at Aberdeen; 500-kw. generating set at Eccles; barometric jet condenser at Middleton; two 200-kw. Diesel engine sets at Reigate; cables at Watford and Partick, and two generating sets at Kettering. It is proposed to spend £60,000 upon a new system of generation at Stoke-on-Trent; loans for electric lighting have been sanctioned at St. Pancras, Stepney, and Woolwich; Greenock Corporation are taking up a loan of £22,000, and an interesting scheme for the utilisation of waste heat is under consideration at West Hartlepool. Tramway materials are required at Colchester and Nottingham. (Page 114.)

W. T. HENLEY'S TELEGRAPH WORKS CO., LTD., declare a dividend of 15 per cent.; Notting Hill Electric Lighting Co., 6 per cent. and a bonus of 2 per cent.; the Waste Heat Company, 8 per cent.; Chelsea Electricity Supply Co., 5 per cent. The Welsbach Company is to be reconstructed. (Page 116.)

ARRANGEMENTS FOR THE WEEK

THURSDAY, MARCH 2ND.

Rontgen Society.

8.15 p.m. At 20 Hanover Square, London. "Some Experiments with a 10,000-volt Storage Battery," by A. A. Campbell Swinton.

SATURDAY, MARCH 4TH.

Junior Institution of Engineers.

3 p.m. Visit to the L.C.C. generating station, Greenwich.

MONDAY, MARCH 6TH.

Institution of Electrical Engineers: Newcastle Section.

7.30 p.m. At Armstrong College. "The Laying and Maintenance of Transmission Cables," by C. Vernier.

Royal Society of Arts.

8 p.m. Cantor Lecture I.: "Applications of Electric Heating," by Prof. J. A. Fleming, F.R.S.

TUESDAY, MARCH 7TH.

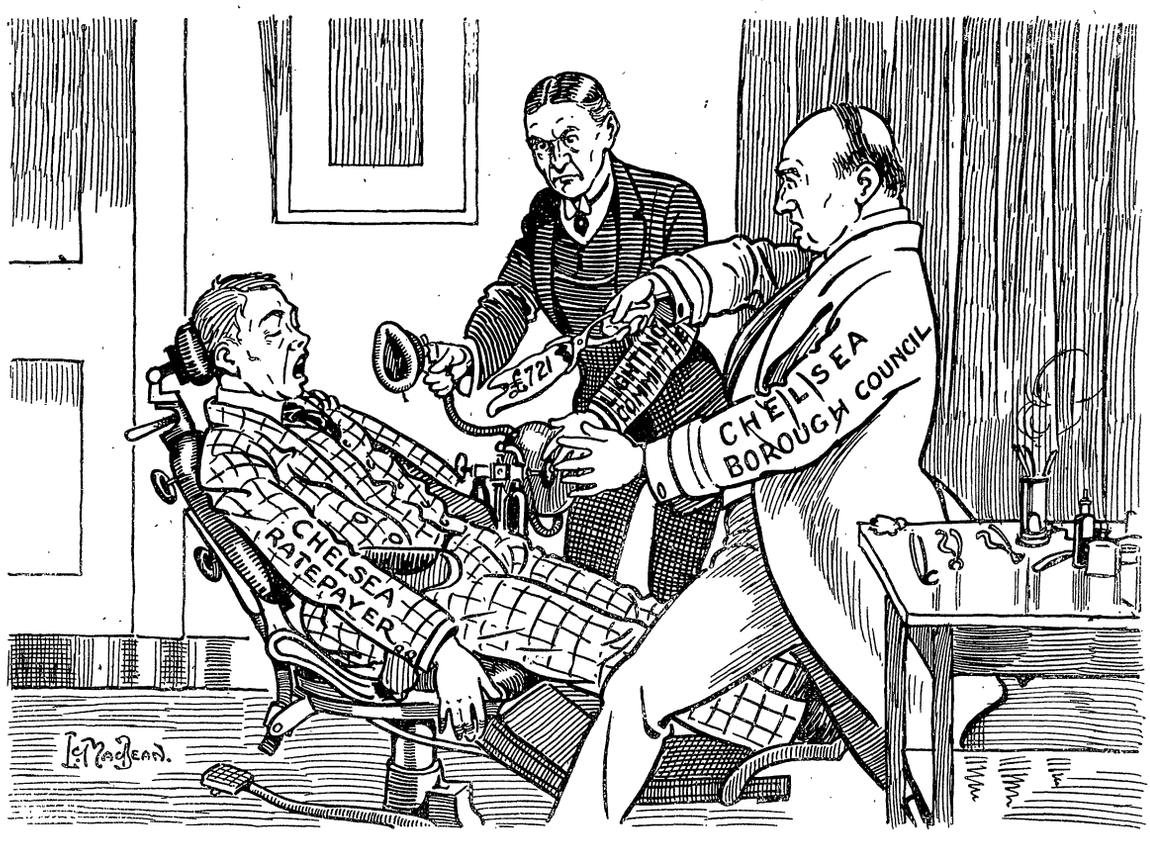
Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. At Municipal School of Technology. "The Development of the Diesel Oil Engine," by W. Cooper.

WEDNESDAY, MARCH 8TH.

Institution of Electrical Engineers: Birmingham Section.

7.30 p.m. At the University. "The Non-Salient Pole Turbo-Alternator and its Characteristics," by S. P. Smith.



THURSDAY, MARCH 9TH.

Institution of Electrical Engineers.

8 p.m. "The Laying and Maintenance of Transmission Cables," by C. Vernier.

Institution of Electrical Engineers: Dublin Section.

8.20 p.m. At Royal College of Science.

"GIVING HIM GAS."

As stated in our last issue, the Chelsea Borough Council, at the instance of the Lighting Committee, have made a contract with the Gas Co. for street lighting for another seven years, although the price paid by the ratepayers will be £103 per year higher than that quoted by the Electric Lighting Co.

Hosted by Google

ELECTRIC DRIVING AT A LONDON PRINTING OFFICE

WITHIN the last two months the whole of the printing machinery employed in the production of the well-known London weekly journals, the *Illustrated London News* and the *Sketch*, has been converted to electric drive. The works have, in fact, been completely reorganised, under the direction of Mr. E. H. Rudd, the general manager of the printing department, and his comprehensive scheme was only rendered possible by the adoption of electric drive. Mr. Rudd has had the assistance of the firm's consulting engineer, Mr. Frank Broadbent, in connection with the electrical portion of the work. The change-over has been effected gradually, so as not to interfere with the regular printing work, and the steam plant is now dismantled. Two horizontal compound engines and two beam engines with their boilers have been displaced, and the release of the valuable space occupied by these for a much-needed extension of the printing plant was an important consideration in determining the proprietors to effect the change. Apart from this, however, a very considerable economy in working expenses will undoubtedly be effected, and the removal of a large amount of shafting will considerably improve the appearance of the rooms and the safety and convenience of working.

The building is situated in Milford Lane off the Strand, and is divided into two portions. The lighting and power

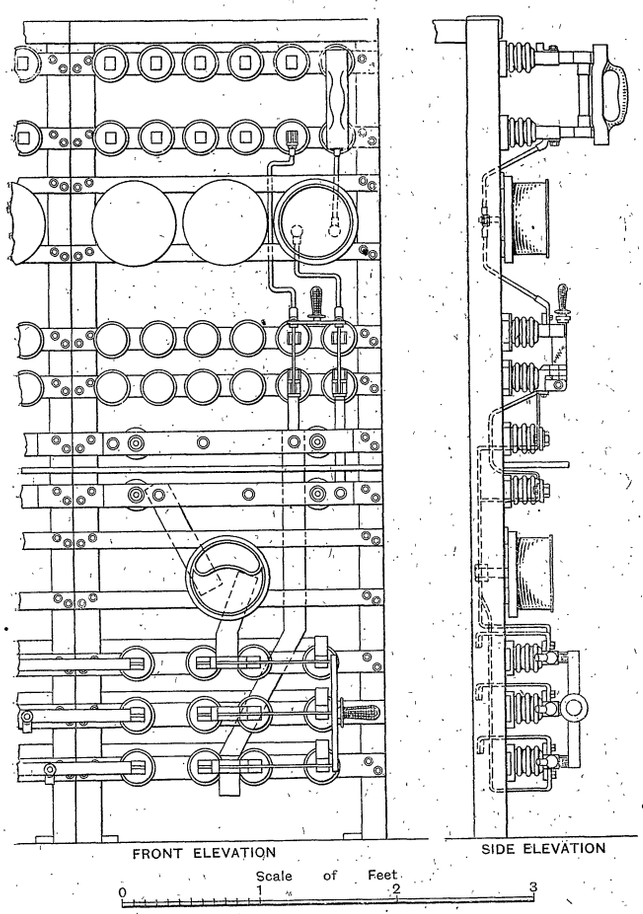


FIG. 1.—SKELETON-PATTERN POWER SWITCHBOARD.

installation is correspondingly divided into two parts, and either section can be supplied from the mains of one or other of two supply companies, the Metropolitan Electric Supply Co. and the Charing Cross, West End & City Electricity Co. Each section is supplied alternately from one of the two companies, a week at a time, in order that they shall share equally the total consumption, but provision is made for switching both sections on to one supply in case of emergency. Each service is three-wire, 200 volts D.C., with 0·5 sq. in. outers. Aron three-wire meters are employed, provided with Merz maximum-demand attachments, which record the maximum demands averaged over half-hour intervals.

The main power switchboard, constructed by Spagnoletti, Ltd., is erected in a separate chamber, together with the lighting boards for the two sections, one on each side. As shown in Fig. 1, it consists of a skeleton steel frame about six feet square, and the fuses, switches, &c., are mounted on porcelain insulators bolted to the steel bars, the switch pivots, connections, fuse blades, &c., being cemented into the insulators. All the connections on the board are of copper strip, and there is no necessity for any space at the back. Eight circuits are provided for, two for 200 amperes and six for 100 amperes. Each circuit has an ammeter, switch-handle cartridge fuses, and a double-pole switch. The leads from this board to the distributing boards on the various floors are heavily braided, armoured, single-core cables, carried along the brick walls. The two 100-volt lighting boards are connected on each side of the three-wire system.

The power distributing boxes on the various floors are of cast-iron, and the armouring of the cables is bonded to them. They have double lids, and only one pole can be exposed at a time. An ammeter is provided at each distributing box with a multiple-contact switch, connected to shunts in all the circuits, so that the current taken by any motor can be

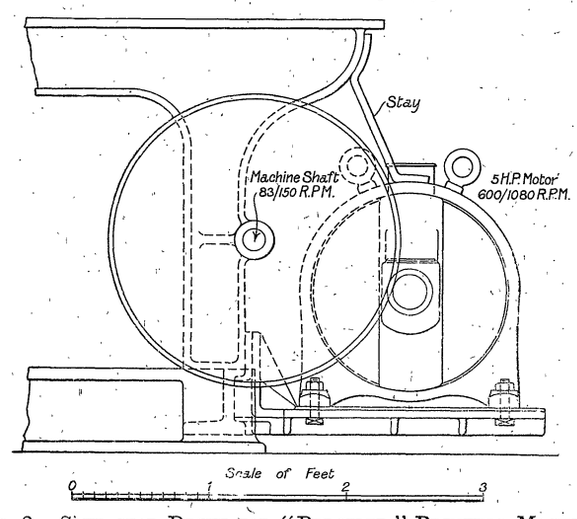

FIG. 2.—SPUR-GEAR DRIVE FOR "PERCELER" PRINTING MACHINE.

measured without interfering with the circuit. From these boxes, armoured twin-core rubber cables are run to the controlling switchgear for the individual motors; the connection between controller and motor is by vulcanised rubber cable in steel conduit. To allow for adjustment of the motor the gland on the motor case is connected to the conduit by a short length of flexible steel tube.

The motors and switchgear were supplied by Messrs. Electromotors, Ltd. (Openshaw, Manchester), to the specifications of Mr. Broadbent. Four large two-feeder "Perceler" flat-bed printing machines are each driven by a shunt motor with spur-gearing bolted up to the machine as illustrated in Fig. 2. A stay is provided to take the upward thrust. The motors are interpole machines with a very wide range of speed obtained by shunt regulation, and are very heavily compounded. The control gear for these large machines is enclosed in a glass-fronted cast-iron box, and is worked from push-buttons on the side of the machine. It consists of a solenoid-operated starter with a separate solenoid main switch and a double-pole manually-operated switch. The shunt-regulating resistance is in a separate box, and as the motors are heavily compounded and the machines rarely run at the highest speeds, there is no provision for ensuring that all the field resistance is out on starting up. Should the machines be set for the highest speed, the motors would practically start up as series motors. During running, the load on the motor fluctuates between 12 and 20 h.p. The machines are stopped by breaking the circuit of the main-switch solenoid and not by short-circuiting it. The control is of Messrs. Marryat and Place's make.

Hosted by Google

Other smaller two-feeder and single-feeder flat-bed machines are driven by smaller motors. Besides the four motors referred to, twelve of 7½ h.p., twelve of 5 h.p., and six smaller ones are installed. Most of the larger ones are driving presses. Spur-gearing with "Unica" pinions is employed in most cases, but there are a few instances of belt drive with jockey pulleys. All the machines have push-button control as described. The folding and stitching machine shafts are controlled by a single solenoid starting switch, brought into action by closing the manually-operated double-pole main switch. The motors for the folders are, in some cases, hung from the ceiling, or supported on brackets from the wall in order to save space, and belt drive has been provided in these cases. Speed regulation is effected in all cases by shunt field control, the use of interpoles and compound windings again making it unnecessary to provide for full field on starting.

In the case of the stitching machines, a very neat arrangement has been produced by mounting them on a platform with belt drive from a line shaft underneath. Among the other machines in use are two large guillotines, three motor-dynamos in the electrotyping room, and a group of bevelling, roughing, and planing machines, &c., in the foundry, driven from line shafting and a single 7½ h.p. motor. The control of these motors is semi-automatic, as in the case of the folders, and a no-voltage release on a switch at the distributing box of this floor protects all the motors against restarting after a stoppage of supply.

Besides the above machines, there are two Cottrell sheet-feed rotary machines, driven by 10 h.p. motors, and equipped with Kohler push-button control. Four push-button stations are provided, one on either side of the delivery end, one at the side of the press, and one underneath, so that the operator can inch the press round when plating the cylinder. Two more of these machines are now being erected, and a further two will be installed shortly. New plant is also to be installed in the foundry; this comprises two new baths, one for electrotyping and one for nickel-steel electros, and a motor-generator capable of supplying 1,600 amperes.

The Chapman Electric Neutraliser is installed in connection with the rotaries and other machines. The object of this device is to dispel the static charge produced on the paper during printing, which causes the sheets to stick to one another and to the machine, and in dry atmospheres produces "offset," bad register, and low working speeds. The "Neutraliser" consists of a small motor with slip-rings to supply an alternating current to a high-voltage transformer, one terminal of the secondary of which is connected by rubber-insulated cable to a series of needle-points placed just above the sheet as it enters and leaves the press. A brush discharge is produced, and this apparently causes the paper to loose its charge. One transformer will supply a number of machines. The sole agent for this device in this country is Mr. John Robertson (Wardrobe Chambers, Queen Victoria Street, E.C.).

A Waygood electric lift with drum-drive for carrying the sheets from the printing rooms to the folding rooms is being erected. This will be a 1½-ton lift, with automatic control from push-buttons at the different floors. Another lift, originally driven from the main shafting with fast and loose pulley gear, is being provided with electric drive by belting the gear up to a motor.

The wiring for the lighting is carried out in solid-drawn screwed conduit, and the pipes are run into the cast-iron switch and ceiling-rose boxes to ensure continuity. All the lights are plain flexible pendants, with enamelled metal shades. There are about 350 lights in all; those along the middle of the rooms and over the machines are 50 c.p., and 32 c.p. along the side benches. Tantalum lamps are employed on account of the excessive vibration due to the machines. A special arrangement has been provided in the compositors' room. Here there is a general illumination by a few 100-c.p. Siemens "Onewatt" drawn tungsten filament lamps, hung high up and provided with white translucent shades, supplemented by 50-c.p. Tantalum lamps, with dark enamelled shades directly over each compositor's desk. The switches are placed alongside each row of desks on the wall, no switch-holders being used. The contractors for the power equipment were Messrs. Electromotors, Ltd., and for the lighting, Messrs. Pinching & Walton.

In conclusion, we should like to express our indebtedness to Mr. E. H. Rudd, General Manager of the Printing Department of The Illustrated London News & Sketch, Ltd., for giving us facilities to inspect the plant, and to Mr. Frank Broadbent for kindly conducting our representative over the premises, and explaining the various features of the installation.

SCHOOL LIGHTING

At a meeting of the Illuminating Engineering Society on Feb. 16th the subject of "School Illumination" was discussed, both from the point of view of natural and artificial lighting. Dr. James Kerr, Medical Officer to the London County Council, and a number of other gentlemen, dealt with natural lighting, and Dr. N. Bishop Harman, Oculist to the London County Council's Education Department, dealt with the subject from the point of view of artificial illumination. The uses of gas and electricity were discussed, and Dr. Bishop Harman expressed preference for 25 volts rather than low candle-power metal filament lamp made for high voltages. He mentioned two hospitals, in one of which the voltage has been reduced to 25, and with metal filament lamps the effect is perfect in flexibility and softness, whilst in the other 240 volts are used and the lighting is hard and wasteful. He also mentioned some experiments with opal shades on 16-c.p. carbon lamps. One shade tried subtended 110° and had a vertical depth of 3⅛ in. This, however, did not cover the lamp, and the filament was exposed to the teacher's eyes. The other was an 80° shade 5 in. deep. It completely screened the filament and increased the light below the lamp by one-third. He recommended that lamps should be hung slightly in front, and to the left of the students' desks at intervals of not less than 6 ft. and not more than 9 ft. with 16-c.p. lamps and 90° shades. One row of lamps could light two rows of desks in this manner, and a very good lighting effect was produced. His experience of reflected lighting, where continuous and detailed work was required, was unfavourable. The system was adopted in the new Anatomical Laboratories at Cambridge fifteen years ago, but it had been superseded by ordinary glow lamps.

Mr. J. S. Dow gave the results of some investigations which he has been carrying out in a number of schools. In the elementary schools illumination on the desks both by electricity and gas was found to be approximately 2 candle feet, and he suggested this being specified as a minimum for this purpose. The average blackboard illumination was somewhat higher. Figures which he had obtained from Germany show that the standard school illumination there is considerably higher, namely, about 8 candle feet. The glare from blackboards was referred to, and the suggestion made that a strip of tubolite along the top would be the best solution.

Mr. C. A. Baker, Electrical Engineer to the London County Council, referred to the difficulty of laying down a standard of illumination, as so many class-rooms are used for different purposes, for which it was necessary to have a different standard of illumination. During the last five years the London County Council have had six colleges, eighteen elementary schools, four secondary schools, and two special schools wired for electric lighting, and 50-c.p. lamps have been adopted. A school to accommodate 900 children costs £300 to wire, the total candle-power being 7,500, which works out to 10·2d. per c.p. installed and 7¾ c.p. per child. All the lamp ends are frosted, and a globe 14 in. by 7 in. is used. It was not usual in wiring ordinary schools, he said, to be able to select the positions for the lamps in quite so methodical a manner as was supposed by many people, the desks being often rushed in at the last moment, and the various points fixed as near as possible before in such positions as could be judged to be most suitable from information given by those interested. He drew attention to the higher standard of illumination necessary in trade schools as compared with elementary schools, and the following figures of the Arts Crafts Schools of the London County Council were given as the illumination on the work tables :—Wood-carving, 30 candle feet; architecture, 7; silversmiths, 4·5; art, 6·5; book-binding, 8; and compositors, 4 to 9.

The discussion will be continued on March 14th.

The Conference between Municipal Engineers and Contractors.—We are informed that after four meetings of the conference between the representatives of the Incorporated Municipal Electrical Association and the Electrical Contractors' Association (Incorporated), it was finally decided that owing to the impossibility of agreement regarding the contentious matter discussed, that the conference be suspended until further notice, and that each side be free to take any action they may think desirable, subject to the resolutions agreed upon. It was further resolved to recommend that a Standing Joint Committee of four on each side be appointed to try and adjust matters of dispute that might arise.

Electrical Trades Benevolent Institution.—It has been decided again to hold a festival dinner of the Electrical Trades Benevolent Institution, and that this shall take place on April 26th, 1911, at the Hotel Cecil. The association has recently had several cases to deal with, and it is sincerely hoped that the electrical trade generally will give it their very full support, so as to enable it to carry out, not only the granting of temporary relief, but to place it in such a position as will enable it to grant pensions to its qualified members or their widows.

ELECTRICAL ENGINEERING

IN

MINES

Correspondence on any of the subjects dealt with in this Supplement is cordially invited from our Readers.

The Editor is willing to insert letters over a *nom de plume*, but Correspondents should send their full names and addresses in all cases.

Letters should be addressed, "THE EDITOR, ELECTRICAL ENGINEERING, 203–206 Temple Chambers, London, E.C.," and should reach this office by the 21st of the month.

Correspondents are requested to write on one side of the paper only.

REPORT OF THE SPECIAL COMMITTEE ON THE USE OF ELECTRICITY IN MINES.

IN their report to the Home Secretary, the Special Departmental Committee appointed to inquire into the working of the existing special rules for the use of electricity in mines, point out that the conditions have altered considerably since the rules came into force some five years ago, and that they need revision. Whereas the early installations were all direct-current plant, the tendency now is to adopt the three-phase system, and this the Committee consider to be a change in the right direction. After receiving evidence from a large number of representative witnesses, the Committee have drawn up a proposed new code of rules which, they suggest, should apply to metalliferous mines as well as coal mines. The rules relate to apparatus below ground only, with the exception of the switchgear at the pit-head controlling the underground distribution system.

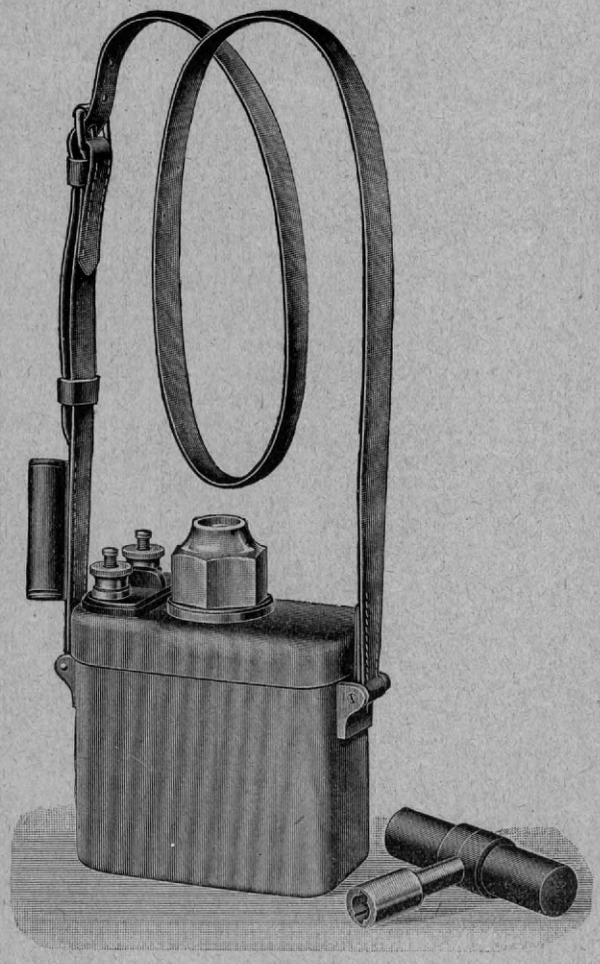
The Committee point out that the number of fatal accidents due to the use of electricity in mines in any one year has never been more than 1·54 per cent. of the total number of fatal accidents in mines, and that most of these electrical accidents are preventible. They consider that electricity should be excluded where outbursts of inflammable gas are very frequent, and the first of the proposed new rules reads as follows:—"The use of electricity is prohibited in any part of a mine where, on account of the risk of explosion of gas or coal-dust, such use would be dangerous to life." In the event of any disagreement as to whether there is danger or not, the question will be referred to arbitration under the Coal Mines Regulation Act. Where inflammable gas, though not normally present, may occur in quantity sufficient to be indicative of danger, certain special precautions, referred to later, are called for. Another new rule prohibits the use of inflammable material in the construction of any room or box containing electrical apparatus, unless the apparatus is so constructed as to obviate the risk of fire.

Whereas the existing rules specify that the local inspector must be notified within three months *after* the introduction of electric power into a mine, the proposed rules provide that notification of the intended introduction of apparatus, and even of the installation of additional plant, must be made, and that the work can only be proceeded with if the inspector does not object within one month. Further, an annual return giving the size and type of apparatus and the circumstances of its use is required, and, as before, a plan of the plant is to be kept up to date. Provision is also made in the new rules for the exhibition of notices prohibiting the handling of plant by other than an "authorised person," directions as to procedure in case of fire, &c.

The Committee do not consider it advisable for the Home Office to approve officially certain types or designs of apparatus, or to issue certificates of competency after examination to persons in charge of plant in mines, but they have specified a number of requirements as regards the design and maintenance of the apparatus. The proposed substitute for Rule 11, requiring the presence in the mine of a "competent" person, specifies that the "electrician," together with the necessary assistants, shall be appointed in writing by the manager, and shall "be competent for the work that he is set to do." No further definition, however, is given as to the "competency" required. Nobody except such an authorised person or a competent person acting under his immediate supervision is to undertake any work where technical knowledge or experience is required in order to avoid danger. The duties and responsibilities of the "electrician" are clearly set forth. He is to make periodical examinations of apparatus, and to test frequently the continuity of the earthing system and all apparatus which is new or has been moved from one part of a mine to another before it is put into service. A log-book is to be kept, and a suggested form for the daily log-sheet is included in the Committee's report. This relates to insulation, reports of routine and special tests, accidents, cases of open sparking, &c., and is to be signed by the electrician and the manager. Certain special precautions and duties with regard to the maintenance of switchgear, machinery, &c., for which the electrician is to be responsible, are also clearly enumerated in the rules. The Committee state, however, in the report that the "electrician" is necessarily under the orders of the mine manager, who is also finally responsible under the Coal Mines Regulation Act, and suggest that the examination for a colliery manager's certificate should require a more extensive knowledge of electrical work than at present. They consider, for example, that the manager should know a good cable-joint from a bad one, and that he should be able to criticise intelligently the maintenance of the electrical plant. Although the "electrician" is directly responsible for the condition of the plant, it is evident that the Committee desire that the main responsibility should rest on the manager himself, but this division of the responsibility raises a debatable question.

With regard to choice of system, the Committee consider that an alternating-current system using high pressure for transmission, high or medium pressures for large motors, and low pressures for small motors and lighting, is safer, more reliable and probably cheaper to instal than a system with medium pressure throughout. Stress is laid upon the necessity for good mechanical construction of machinery, switchgear, and cables, and several new rules in connection with earthing and insulation are proposed.

Whereas earthing is now specified only in the case of cable sheaths and armourings *other* than trailing cables, switch-cases, and machine frames *other* than portable motors, and then only when the pressure exceeds 250 volts, a new rule covers all apparatus at pressures above 250 volts D.-C. and 125 volts A.-C., including trailing cables, joint-boxes, instrument covers, all lampholders unless protected by a fire-proof insulating material, and all machines *including* portable motors. It is further specified that they shall be earthed by connection to an earthing system at the surface of the mine, and that all earth conductors other than the metallic covering of cables shall have a conductivity at all parts and at all joints at least equal to that of the largest conductor supplying the apparatus it is desired to earth. In the case of cables, the metallic covering is to have a conductivity at least equal to 50 per cent. of that of the largest conductor in the cable.



The rule relating to the insulation of a system permits as before the earthing of the neutral point of a three-phase system and the mid-voltage point of any other system both at one point only. The outer conductor of a two-wire concentric system must be earthed. In all cases this earthing is also to be done by connection to an earthing system at the surface of the mine. Means are to be provided for indicating any leakage, but the limit of 1/1,000th of the maximum supply current is not now prescribed. An important new requirement relates to cutting off pressure automatically in the event of a fault or leakage, and the Committee now seek to make this compulsory. This recommendation, if adopted,

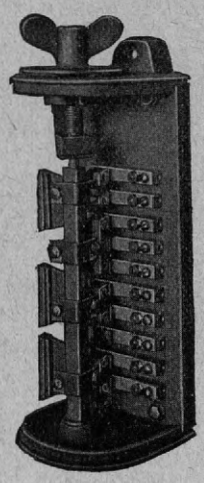
WORKS:—DAGENHAM, ESSEX.

will, of course, entail considerable alterations to existing switchgear.

As is the case at present, high pressures are limited to stationary machines of over 20 h.p. Switchgear, according to the proposed rules, is to be constructed so that the lodgment of dirt or coal-dust on or close to live parts is prevented, and all live parts even at low pressures are to be protected so as to prevent accidental contact by persons. The new rules prescribe that switchgear for cutting off the supply shall be provided at the surface within 200 yards of the pit-head, and that telephonic communication be provided between the shaft-bottom or main distributing centre and this point, an authorised person being available within easy reach of the latter. In a concentric system the switchgear must be so arranged that the continuity of the earthed outer is never broken.

With regard to cables, the proposed rules provide that all multiple-core or concentric cables, other than flexible trailing cables, shall have a metallic sheath where the pressure exceeds 250 volts, where the roadway conveying the cables is also used for haulage, or where there is risk of igniting gas or coal-dust. Single-core cables need not have this sheath, but must either be enclosed in a pipe containing all the conductors of a circuit or must be secured to insulators by readily breakable material. All sheathing or armouring is, of course, to be electrically continuous throughout, and is to be earthed to the earthing system by a connection of not less conductivity than the same length of the armouring. The sheathing is to be protected against corrosion where necessary. Flexible cables for portable apparatus are to be multiple-core, and, if armoured, the armouring is not to be the only earth conductor, but an additional earth wire is to be provided. Proper connectors are to be used. The lampholders of portable lamps are not to be in connection with the guard or other metal-work.

The special precautions referred to above as being required where inflammable gas may occur are, first, the use of motors, cables, apparatus, and signalling instruments especially constructed to obviate the risk of "open sparking." The current is to be switched off immediately sparking occurs or while examination or adjustment disclosing parts liable to spark is being made. Secondly, every electric lamp is to be enclosed in an air-tight fitting, with an hermetically-sealed globe. Thirdly, a safety lamp is to be provided near each motor, and should any indication of fire-damp be given, the attendant must switch off current and report the matter.



The rule relating to shot-firing prohibits the use of current from lighting power circuits for this purpose in any circumstances. The pressure for signalling circuits is limited to 25 volts. Electric relighting apparatus is to be subject to substantially the same regulations as at present, except that its use is prohibited in any part of a mine to which the special precautions apply, namely, where inflammable gas may occur in dangerous quantities. Haulage by electric locomotives on the overhead trolley-wire system is, according to the proposed rules, prohibited in any part of a coal mine, but may be used in mines other than coal mines with the consent of the Home Secretary and subject to any conditions as may be prescribed. Storage-battery locomotives may be used in any mine subject to the consent of the Home Secretary.

Exemption from the requirements of any of the rules can be obtained from the Home Secretary on the ground of emergency or special circumstances, and special exemption from strict compliance with the rules providing for the use of cables with earthed metallic sheathing at or below medium pressure (650 volts), can be obtained if it can be shown that there is no risk of igniting gas, coal-dust, or other inflammable material.

In a memorandum accompanying the proposed rules, several practical points which may arise in the carrying out of the rules are alluded to. It is suggested that the periodical tests of insulation should be made with an ohm-meter giving preferably double the working pressure of the system. A portable testing transformer giving double the normal pressure of the system should also be available in the mine where an A.-C. system is employed. It is stated to be desirable to connect the earthed point of a system to the earthing system, and not to a separate earth-plate. The neutral of a three-phase system should be earthed in any case, but the mid-point of a D.-C. system only if the cables have a metallic sheathing. Such earthing is recommended, however, together with the use of automatic leakage cut-outs, as being the simplest way of indicating a fault. Commenting on the rule as regards connection of all frames, armouring, &c., to an earth-plate at the surface, it is stated that two earth-plates placed 20 or 30 ft. apart and connected together are far better than a single larger plate. A cast-iron plate with pro-

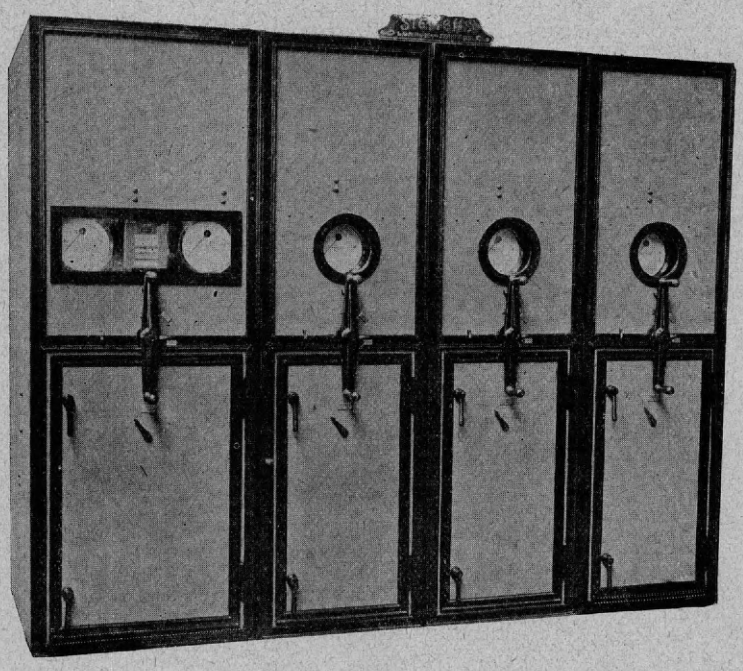
D D O Switch.

jecting forks placed in an upright position and packed hard on each side with broken coke is recommended. The connection should be riveted along the plate, and afterwards soldered along the edges to preserve the contact surface from corrosion. It is noted that the earthing of apparatus is not required for pressures lower than 250 volts D.-C. or 125 volts A.-C., and it is suggested that the pressure for lighting in A.-C. installations should be 50 volts or less. The use of auto-transformers is objected to on account of the risk of the lampholders becoming charged to the primary pressure. For higher voltages than the above limiting pressures, it is suggested that a special earth wire should be provided for earthing each lampholder, or that the lamp and holder should be enclosed in an outer globe, such as is used in battery-rooms, and known as an "acid-proof" fitting. Referring to earth connections, it is stated that a good earth connection should be regarded as of even greater importance than a good connection in the supply circuit.

With regard to the use of high pressures, it is suggested that it is better to transform down for motors of 50 h.p. and under when the supply is at 3,000 volts, and if the supply is at a higher pressure it is recommended to transform down for motors of 100 h.p. or less. Small lighting transformers may be run in solid with insulating compound, while large transformers should be oil-immersed. The secondary circuits should be earthed at one point to avoid risk of the pressure rising to a high value by contact with the primary. Where this is undesirable, as in local lighting circuits, an earth-shield between the windings is recommended. Referring to the construction of switchgear, it is stated that this should be dust-proof, moisture-proof, and so designed as to "prevent open sparking," but no mention is made, either in this case or when referring to motors, of the possibility of securing a flame-proof construction by the adoption of plate-protection or of wide flanges. It is noticeable that the so-called "gas-tight" construction is very properly not insisted upon. To ensure that there shall not be open sparking in the event of a fault in a cable, it is recommended that the metallic sheath nearest the conductors should be air-tight as is a lead sheath, or should be enclosed by another sheath, as when armouring is put over an inner copper sheath with a moderately thick bedding of jute or other material between. In both cases the object is to prevent the arc from penetrating to the outside of the cable before the current is cut off. Wire armouring is preferred to tape armouring, and double to single armouring. It is pointed out that the ends of armoured cable should be finished off by securing the armouring to a spigot or to a gland screwed into the switch-box or cable-dividing box. Cable boxes should be supported on a brickwork base in a recess by the roadside, and bonding of the metallic sheaths inside or outside the box is necessary. Armouring is said to be undesirable for trailing cables. It is recommended that a plug should make the earth connection before the supply connection, but though it is stated that the current should not be on when the plug is being inserted or withdrawn, the use of plugs and sockets automatically interlocked with the switch to prevent this occurring is not referred to. Finally, with regard to the special precautions for places where inflammable gas may occur, it is pointed out that these can hardly be considered "special" requirements, as armoured cables and the best type of switchgear and motors are desirable in any case.



It may be mentioned that in reply to a question in the House of Commons last month, the Home Secretary stated that it would not be necessary to introduce legislation to establish the revised rules, and that he would consider whether steps could be taken at once to bring them into force under the procedure provided by the Mines Regulation Acts.

The Whitehaven Colliery Disaster.—The reports by Mr. R. A. S. Redmayne and Mr. S. Pope on the explosion and fire at the Wellington Pit of the Whitehaven Colliery, in which 136 lives were lost, have been published. The explosion is attributed to the ignition of firedamp and coal-dust; the cause of ignition is not known, but is stated to have been probably due to a defective safety lamp. No electrical plant was used in the pit. Mr. Redmayne suggests that miners working in the neighbourhood of goaves where the roof consists of a bed of hard rock which does not readily fall or bend should be provided with electric lamps instead of oil safety lamps.

ELECTRICALLY OPERATED COAL HOISTS

THE Paper by Mr. Walter Dixon and Mr. J. H. Baxter on "Modern Electrical Dock Equipment," with special reference to electrically-operated coal hoists, was further discussed at the Institution of Mechanical Engineers on Friday, February 17th. We abstracted the Paper and previous discussion in ELECTRICAL ENGINEERING IN MINES for February 2nd.

Mr. WALTER PITT (Messrs. Stothert & Pitt) expressed the opinion that an electric generating station at a dock was a more useful general servant than a hydraulic station, on account of its greater flexibility in transmission of power, and also the various uses to which electrical power could be put, compared with hydraulic power.

Mr. ROGER T. SMITH (electrical engineer, Great Western Railway) advocated the use of belt conveyors in preference to hoists, and pointed out that they needed much smaller motors. A small clay conveyor of the belt type, which his company was using in Cornwall, had shipped 10½ tons per kw.-hour, as against 7 tons per kw.-hour with the Rothesay hoists. He mentioned that the Great Western Railway Co. had ordered twenty-eight "Clyde" electrical capstans on account of their great economy. The maximum demand on the generating station, compared with the slipping rope capstan, was decreased 50 per cent., and the energy by 30 per cent., but much more important was the saving in the cost of ropes.

Mr. C. S. MEIK had come to the conclusion that the capital cost for both types of plant was practically the same; that the cost of power with full load was the same, but on a variable load the electrical machinery had the advantage; that in working and maintenance, hydraulic machinery had the advantage.

Mr. C. J. HOBBS (Hydraulic Engineering Co.) remarked on the full-load condition not having been realised at Clydebank, and objected to the selection of hydraulic machinery for comparisons, which was anything but modern. The hydraulic capstan was not remarkably economical, but it withstood rough usage better than the more delicate electric capstan.

Mr. E. G. BREWER advocated the use of high-capacity coal waggons in conjunction with gravity loading.

Mr. MORRISON expressed the opinion that the authors had done away with the flexibility which was a feature of electric driving by giving each hoist a separate generator, and pointed out that it was necessary to run the flywheel even if only one hoist were being used.

Mr. E. KILBURN SCOTT preferred batteries and boosters to flywheels; and, regarding the question of running flywheel in a vacuum, compared the much greater effect of the vacuum in the case of speeds such as of the Brennan gyroscopes.

Mr. J. A. F. ASPINALL (Lancashire and Yorkshire Railway Co.) had a great deal of both classes of machinery, electrical plant being put in when the load was very variable. He did not think that the authors had had sufficient experience yet to really say that the electrical plant was more economical with regard to maintenance than hydraulic machinery. Electrical appliances which would adjust themselves absolutely to the load would probably show some points in economy, which might compensate for the greater cost of maintenance if this latter were found to exist.

The PRESIDENT (Mr. E. B. Ellington) thought that the matter would have to come up for further discussion in a year or two. The variety of opinions certainly showed that the question of which would be the power of the future for docks had not been finally settled.

Mr. WALTER DIXON and Mr. G. H. BAXTER both replied briefly.

THREE-PHASE HAULAGE MOTORS

A DISCUSSION on three-phase motors for haulage in mines was opened by Mr. J. Simpson at a meeting of the North of England branch of the Association of Mining Electrical Engineers on February 8th. The author briefly considered the points to be noticed in drawing up specifications of such machines. From considerations of weights, speeds, gradients, and distances, the h.p. required is easily calculated, and some 25 to 30 per cent. should be added for rolling friction and contingencies. The motor speed is settled in relation to the gearing and diameter of the drums, having in mind the frequency of the circuit. The speaker recommended wound rotors and an air gap at 1/500th the diameter of the rotor, and advised that maximum efficiency should be sought at ¾ the rated load, and an overload capacity of 2½ times full load specified. He favoured tunnel windings with gun-metal or bronze slip-rings with brushes only on the upper half. A model specification was given based on a 70° F. temperature rise after six hours on full load, or 90° F. after 15 minutes at 50 per cent. overload.

DISCUSSION.

The discussion was opened by Mr. Baxter, who considered that 400 r.p.m. was the best speed for haulage motors. He criticised several points in Mr. Simpson's proposed specification, such as the air-gap being given as a definite fraction of the diameter, irrespective of the weight of the motor and the proportions of the shaft. Mr. Clatworthy asked for opinions regarding the method of bringing out the connection to the star point of the winding. Mr. Park and Mr. Ralph, in connection with air-gaps, favoured adjustable bearings, and some discussion ensued on the relative advantages of split and solid bearings. Mr. Moley raised the question of controllers, and the general opinion was in favour of the drum type. Mr. Simpson in his reply said that in his experience speeds above 400 r.p.m. resulted in objectionable vibration. He considered that much lower speeds should be employed in haulage than in pumping work. He had had trouble with former-wound coils, and much preferred tunnel construction. Large air-gaps were particularly important in haulage motors, as the reversal and backlash of the gear caused excessive wear on the bearings. He much preferred metallic to liquid controllers. He was in favour of bringing out the central point of the windings.

THE PRETORIA PIT EXPLOSION

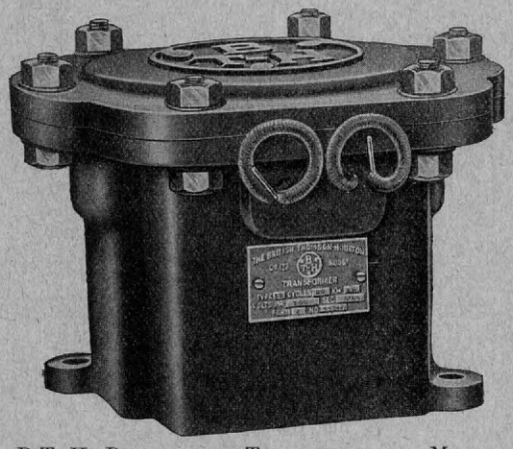
THE inquest on the 344 victims of the explosion at the Hulton Colliery on December 21st was concluded on February 13th, after lasting twenty-seven days. The jury found that the explosion was due to an accidental ignition of gas and coal-dust on the conveyor face in the North Plodder mine, and state that, while the cause of ignition is unknown, it was probably due to a defective or overheated lamp. They add that there was no evidence to prove that the explosion was due to the non-observance of any statutory obligation, but criticise the ventilation of certain headings. Referring to the electrical plant, the jury call attention to the need of skilled supervision, and suggest that switches in places where gas occurs should both break under oil and be enclosed in gas-tight boxes. (The latter suggestion is founded upon mistaken ideas, but it may be presumed that a flame-tight case would meet their desires.) More thorough reporting of ventilation is urged, as well as full investigation into the dangers incident to coal-dust and as to the character of safety lamps. In his summing up, the coroner criticised very severely the reports available on the ventilation. He pointed out that the experts called on behalf of the Miners' Federation supported the view that the conveyor switch caused the explosion, whereas the experts for the colliery company and the Home Office excluded it as a probable cause.

The Home Office inquiry into the cause of the explosion was opened at Westhoughton on February 20th by Mr. R. A. S. Redmayne, H.M. Chief Inspector of Mines. Mr. Tonge, general manager of the Hulton Collieries, has given evidence with regard to the ventilation and the electrical plant, stating, with regard to the latter, that the switchgear was examined daily by a competent electrical engineer. In places where gas was liable to occur, oil immersed and fully protected switches were used, as required by the Special Rules, and he was absolutely sure that the electrical plant had nothing to do with the explosion. He had come to the conclusion that the explosion started near the top of the No. 2 jig in the North Plodder mine, and not at the conveyor face, as suggested by the jury at the inquest. The cause was, he thought, a broken lamp at a fall.

ELECTRICAL MINING PATENTS OF FEBRUARY

AMONG the patent specifications published during the past month of interest to mining electrical engineers, was No. 29,789 of 1909, by E. Gottschalck, of Berlin, for a miner's electric safety lamp. This consists of an accumulator lamp provided with a reflector of glass or porcelain, which is broken if the lamp receives a mechanical shock sufficient to break the lens or lamp. A strip of metallic powder, burnt or deposited on to the back of the reflector, is connected in the lamp circuit, and thus the current is cut off if the reflector is broken.

Specification No. 1,383 of 1910, by Mavor & Coulson, Ltd., and M. Dempster, describes the use of a flexible cable extending from the head to the foot of an inclined working to prevent a coal-cutter from travelling down the incline in the event of the haulage gear failing. The cable can be wound on a drum on the machine, which may be caused to prevent or regulate the downward travel of the machine.



A specification by the British Thomson-Houston Co. and E. B. Wedmore (No. 6,292 of 1910) relates to protective systems for D.C. distribution networks in which the series wound trip coil depends for its operation upon the difference in current between the positive and negative mains feeding the faulty section, and covers the use of shunt windings to render this device more sensitive.

A miner's electric safety lamp with a magnetic lock is described in Specification No. 12,368 of 1910, by P. L. Trin, of Paris. The lock comprises two caps screwed in reverse directions, and a pin passing through both caps and resting on a stop the movement of which is controlled by an electro-magnet.

A TRANSFORMER FOR MINING BELLS

IN view of the troubles sometimes experienced with primary batteries, the British Thomson-Houston Co., Ltd., have brought out the special pattern of transformer illustrated here for the purpose. The transformer is mounted in a strong explosion-proof cast-iron box, having a bolted-down cover with a wide machined joint designed to withstand 140 lb. pressure per square inch. Double-pole fuses of the cartridge type are mounted inside the box and connected in series with the primary coil. The coils are kept apart by a metallic

B.T.-H. Bell-ringing Transformer for Mines.

separator connected to the case to avoid any possible leakage from primary to secondary. The leads are brought out of the box through sealed insulating bushings. The transformer is wound for a normal voltage of 500 at 50 cycles on the primary and 20 volts on the secondary. By an arrangement of clearly marked tappings, inside the case, the secondary voltage may be changed to approximately 17, 15, or 13 volts. The primary may be used on any voltage up to 600 at 50 cycles, the secondary voltages being proportionately increased. The winding is so designed that the secondary coil may be left short-circuited for five minutes without damaging the transformers. The iron loss does not exceed 8 watts.

OIL-IMMERSED MOTOR-STARTERS

A NEW pattern of totally enclosed oil-immersed starter of the star-delta type for squirrel-cage motors has been brought out by George Ellison (17 and 18 Warstone Lane, Birmingham). These are made in two sizes with contacts for currents up to 50 and 100 amperes respectively, and are fitted with a slow-motion device that prevents the operator putting the starter into the running position unless he has first held it in the starting position a certain length of time to allow the motor to get up speed. It is also impossible to leave the starter in the starting position unless held there by hand. They are fitted with a no-voltage release, which, besides giving protection against failure of supply, can be used for stopping the motor from a distance by emergency switches in the no-voltage coil circuit. The overload releases can be fitted with adjustable time lags. In the standard pattern two overload releases and one no-voltage release are provided, all acting on the retaining hook, and the connections are so arranged that the overload coils are not in circuit until the running position has been attained. The releases are adjustable from full load to 60 per cent. overload. In this type two handles are fitted, one for working the starter, and the other, a small one, for tripping. The latter can also be turned in the opposite direction for holding down the releases and preventing them tripping when the starter is being thrown into the running position. This arrangement is, however, not necessary when time lags are fitted. Fuses can be substituted for the releases if desired. These are contained in a separate chamber, the cover of which is interlocked with the starter so that the fuses are not accessible unless the starter is in the "off" position. The fuses are arranged not to be in circuit in the starting position.

Royal Commission on Accidents in Mines.—This Commission, which is quite apart from the Special Committee on the use of Electricity in mines, has practically concluded its labours, and it is stated that the miners' representatives in the House of Commons will press for a new Mines Act this year, based on the recommendations in the report of the Commission.

Articles of Interest to Mining Electrical Engineers published in "Electrical Engineering" during February.

Feb. 2nd.—Monthly supplement on Electrical Engineering in Mines, opening with an abstract of a Paper on electric power in collieries by Mr. J. Miller, expressing a preference for three-phase working, and emphasising the advantages of the bar type of coal-cutter. A report is also given of a Paper recently read before the Institution of Mechanical Engineers describing the electrical coal hoists at Clydebank. Other articles include a description of the electrical equipments of an eastern tin mine and a New Zealand coal mine. A report of a Paper on mining switchgear is also given, and the electrical mining patents published during the month are reviewed.

Feb. 9th.—An article comparing the prices of aluminium and copper cables. Report of a discussion on high-tension transmission. Illustrated description of a three-phase goods locomotive. Report of a discussion on transformer sub-stations.

Feb. 16th.—Literary supplement, with reviews and list of recommended books in all branches of electrical engineering. Announcement of the publication of the report of the Home Office Committee on electricity in mines. Description of a new voltage regulator.

Feb. 23rd.—Some particulars of an electric pumping station. Notes on a new alternating-current starter and aluminium three-core cables. Illustrated description of the new power station at the Midland Railway Works, Derby, with particulars of the new Willans' "Disc and Drum" turbine.

PARALLEL WORKING OF ALTERNATORS

THE Paper on the above subject, prepared by the late Mr. J. R. Barr, for the Glasgow Section of the Institution of Electrical Engineers, was discussed at a meeting of the Section on February 14th. The author points out that the engine governor usually maintains the speed up to full load within from 3 to 6 per cent. of the no-load speed, but must not be so sensitive as to respond to the regular speed oscillations of reciprocating engines. On account of this and friction, there must be a certain change in speed before the throttle valve operates. Consequently, when several alternators are working in parallel, they may be unequally loaded, as the load, and consequently the speed, of any one may vary between certain limits without affecting its governor. The possible difference of loading will be the greater, the smaller the percentage speed drop of the governor, and the wider the limits of speed variation for a given position of the governor. A large governor drop is therefore an advantage in so far as parallel running is concerned, but involves a corresponding variation in frequency. Where this must be the same for all loads it is necessary to alter the sensitiveness of the governor as the load varies, either by hand or automatically. For lighting plants hand regulation is quite sufficient, but for power plants automatic regulation in the form of a relay controlled from the switchboard is essential.

After explaining the phase displacement and consequent synchronising currents resulting from the acceleration or slowing down of the affected alternator before its governor comes into play, the author shows how these currents produce a free oscillation about the synchronous position due to the momentum of the rotating system, and how these oscillations are damped by eddy and local currents in the armature conductors, pole-shoes, amortisseurs, or field-coils, with the result that the alternator ultimately settles down. The periodic time of the free oscillation is shown to vary directly as the square root of the moment of inertia and inversely as the ratio of short-circuit current to normal full-load current. For steady running, the time of swing should be long, and therefore it will be of advantage to design an alternator for a high reactance so as to decrease the above ratio. Machines with inferior regulating properties are therefore well suited for parallel working. Where only free oscillations exist, no trouble will be experienced; thus turbo-alternators having uniform driving torque have given practically no trouble when operated in parallel.

The author then points out that the variation of speed produced by the irregular turning moment of a reciprocating engine may be considered as forced oscillations impressed upon the alternator-field system, and shows how to deduce the consequent phase displacement. This is directly proportional to the coefficient of speed variation or cyclic irregularity and inversely proportional to the number of cycles per revolution. The synchronising torque magnifies this displacement, however, which in turn produces a larger synchronising torque, and to obtain the final value the author applies the method described by Dr. E. Rosenberg, in a Paper before the Institution (see ELECTRICAL ENGINEERING, February 4th, 1909, p. 110). This brings in a "reaction coefficient," q, equal to the ratio of the synchronising torque caused by the phase displacement to the variable oscillating torque due to the prime mover. The final value of the synchronising torque is expressed by $qT/1-q$, where T represents the initial value of the variable oscillating torque obtained from the diagram of crank effort. If $q=1$, resonance occurs, and the final oscillations would be infinite, and this happens when the period of the oscillating torque is equal to the period of a free oscillation. Even when q approaches unity, oscillations started by any small speed variation may increase to such an extent that parallel running is impossible. Although it is desirable to keep the initial displacement small, stable running does not depend so much upon this as upon the value of q.

In actual machines, however, the free oscillations are damped to a more or less extent by the presence of a third torque, due to the eddy and local currents referred to above, which are produced by the oscillations themselves. When amortisseur coils are fitted into the pole-shoes the damping torque will be high. With solid pole-shoes, the higher resistance of the iron will reduce the damping torque. With laminated pole-shoes the torque will be still further diminished, but as the laminations do not permit of large damping currents, the action will go deeper and will be visible in the field coils. The author then shows how to take into account this damping torque, which can be determined experimentally by running the machine as an induction motor and loading on a suitable brake. The slip corresponding to any particular load is measured, and the ratio of brake torque to slip will be the same as the ratio between damping torque and oscillating speed. In spite of the influence of the damping torque the natural period of the alternator should, in general, be at least 1·4 times the period of the impulses impressed by the prime mover. If this condition holds, dampers are quite unnecessary, but when the flywheel effect is such as to give nearly the critical value for parallel working, then the use of dampers may save tons of flywheel. In general, it may be said that dampers should always be used when the natural period is less than 1·4 times the period of the impressed impulses.

In practice a number of machines of different types and speeds may have to run in parallel, and in such cases it is not only necessary to avoid equality between the natural frequency of each machine and the impulses of its own engine, but also with the impulses from the other engines. The prevailing type of engine in this country runs at such a high speed that most of the difficulties are avoided, but in the case of alternators driven by slow-speed engines the possibility of trouble from resonance should be investigated.

The author concludes with some notes on the permissible values of phase displacement and cyclic irregularity, and on the necessary size of flywheels. In medium-speed sets the size of flywheel necessary for mechanical reasons will generally be ample. In a slow-speed engine with a fixed flywheel effect, the critical value can be avoided by increasing the radial depth of air-gap so as to increase the apparent impedance of the armature, and therefore the value of the short-circuit current. Such a procedure may, however, endanger the regulating properties of the alternator.

Before reading Mr. Barr's Paper, Prof. F. G. BAILY referred to the author's short career. He was born in 1885, and served his apprenticeship with Bruce Peebles & Co., Edinburgh, thereafter spending a year at the Leith Power Station. He attended evening and later day classes at the Heriot Watt College, Edinburgh, and then joined the Electrical Construction Co. at Wolverhampton. When only twenty years of age he was sent to East Africa to erect a consignment of plant, and was successful in carrying out the work satisfactorily, although he unfortunately contracted malarial fever, which returned periodically after his return. Since then he has been assistant lecturer of electrical engineering at the Heriot-Watt College. In 1908 Mr. Barr published a book on the "Elements of Direct-current Engineering," and has just completed another work on "Alternating-current Machinery."

Mr. J. S. NICHOLSON (Glasgow University), after referring to the author's earnestness of purpose and keenness for work and to the excellence of his book on direct-current machinery, exhibited some curves of turning moment obtained from the Glasgow Corporation three-crank reciprocating engines, and emphasised the necessity for a careful consideration of the turning-moment diagram before making assumptions regarding the sine curve which may be substituted for the irregular oscillating torque referred to in the Paper. In reply to a question by Mr. Day, Mr. Nicholson said that the displacement, with two of the alternators running in parallel, would be only 1¼ electrical degrees. The usual allowance was plus or minus 3 degrees.

Cumberland Branch of the Association of Mining Electrical Engineers.—Mr. W. Maurice, President of the Association, paid a visit to this branch on February 18th, and gave an address at the meeting at Whitehaven. He outlined briefly the ground the Association was intended to cover, and emphasised that although it was open to all in any way connected with the applications of electricity to mining, it was primarily intended for the interests of the craftsman. There were now ten branches and nearly 1,000 members. He referred to the way in which the growing application of modern engineering methods to mining had drawn a new class of man into the mining industry, and it was this that had led to the foundation of their Association. The installation of electrical machinery in mines had developed into an economic necessity, and had been forced upon mine owners by the increased cost of mining coal, a substantial portion of which has been caused by legislation designed for the protection of the workers. Labour legislation had since 1842 added some £26,000,000, or at least 2s. per ton to the cost of mining coal. The use of electricity enabled the mine owner to meet a portion of these extra costs, but also aided the worker by increasing the number of workable properties. It also made underground work less arduous. There had been an outcry about the dangers of electricity in mines. It was true that there were dangers, but they were more than counterbalanced by the way the application of electricity had lessened other risks. Much was being done to lessen such risks as there were, and at no distant date the use of electricity in mines would be as safe as is humanly possible. Mr. Maurice outlined the organisation of the Association, and also referred to the arrangements for the examination scheme.

VARIABLE SPEED INDUCTION MOTORS

THE induction motor has hitherto been mainly used for constant-speed work, but its inherent good qualities are causing increased attention to be paid to rendering it suitable also for cases where variable speed is essential.

A ready way of doing this is to arrange the stator windings so that the numbers of poles can be varied, while the rotor is provided with the squirrel-cage type of winding. A two to one speed variation can be obtained with a single winding on the stator, and a simple throw-over switch for re-connecting the winding from one number of poles to the other. By using two windings on the stator, each arranged for a two to one speed variation, four speeds can be obtained. For example, if one winding is arranged for four and eight poles, and the other for six and 12 poles, then with a 50-cycle supply synchronous speeds of 1,500, 1,000, 750, and

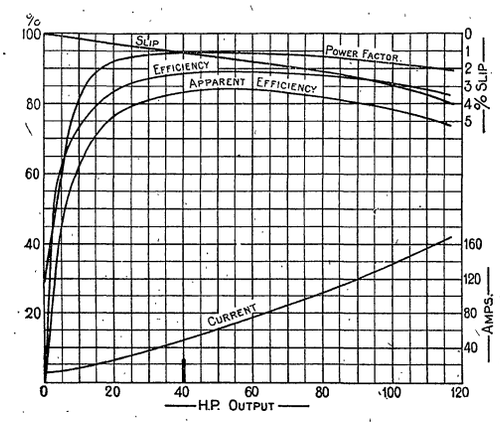

FIG. 1.—CURVES FOR HIGHEST SPEED (4 POLES).

500 r.p.m. are available. As these speeds are obtained without the use of any resistances external to the motor windings, such machines can be designed to operate with high efficiencies.

The British Thomson-Houston Co., Ltd., of Rugby, have recently built several such motors for variable-speed drive, and Figs. 1, 2, and 3 show characteristics obtained from actual tests on a three-speed machine with two windings on the stator, one for four or eight poles, and the other for 12 poles. On a 50-cycle circuit the synchronous speeds were 1,500,

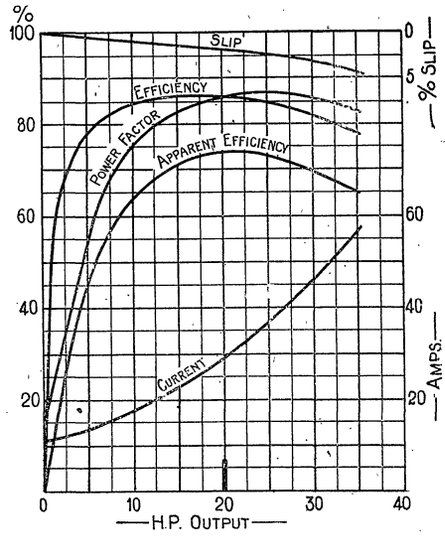

FIG. 2.—CURVES FOR MEDIUM SPEED (8 POLES).

750, and 500 r.p.m., the corresponding full-load speeds being 1,485, 735, and 490 r.p.m. The horse-power ratings corresponding to these speeds were 40, 20, and 14 respectively.

Another machine was arranged for synchronous speeds of 500 and 375 r.p.m. on a 25-cycle circuit, with winding for six and eight poles respectively in the stator slots. A throw-over switch was mounted on the frame for changing over.

While the above type of machine, having several definite speeds, meets the requirements in most cases, it is, however, desirable occasionally to have a machine suitable for operating at any speed from the maximum down to 15 per cent. or 20 per cent. above zero speed. To use an ordinary slip-ring motor with resistances inserted in the rotor circuit to give the total speed variation required is very inefficient. Much more efficient working can be obtained by building the motor with a changeable pole stator winding, and also a changeable pole rotor winding. A straight two to one ratio requires only a single winding on the stator and a single winding on the rotor. A simple throw-over switch on the stator is all that is necessary to change the speed from full speed to half speed, and at both these speeds a highly efficient machine is obtained. To obtain any speed between full speed and half speed and zero speed, it is necessary to insert resistance in the rotor circuit, but it will be readily seen that the losses in reducing the speed of this type of

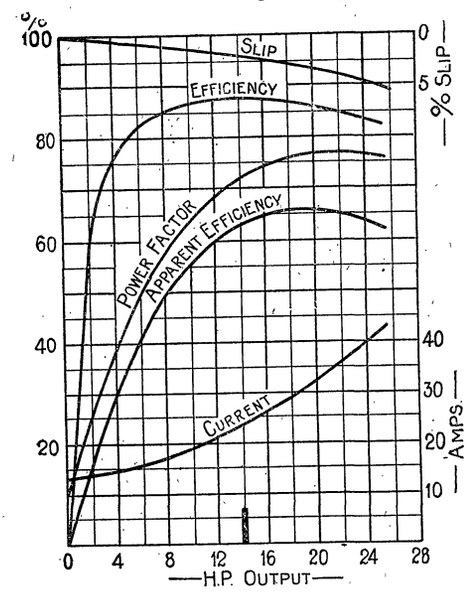

FIG. 3.—CURVES FOR LOWEST SPEED (12 POLES).

machine down to, say, 25 per cent. of maximum speed are much less than if resistance had to be introduced to take care of the complete reduction in speed from full speed down to 25 per cent. of same.

In a motor of this class recently built at Rugby by the British Thomson-Houston Co., Ltd., the rotor was wound six-phase with six slip-rings. No other switching device except the usual controller was necessary in the rotor circuit. The machine in question was built with windings arranged for eight and 16 poles to give synchronous speeds of 600 and 300 r.p.m. respectively on a 40-cycle circuit, the output at these speeds being 15 and 7½ h.p. respectively. A 40 per cent. speed reduction below maximum and the same below half speed was required. The starting characteristics of this machine are similar to those of an ordinary slip-ring motor.

LIGHTING IN THE BOROUGH OF HOLBORN

AS was pointed out in our article on the lighting of Holborn (see ELECTRICAL ENGINEERING, February 16th, page 81), the present gas contracts expire on March 25th, and as no decision has yet been come to with regard to the improved lighting, an arrangement has been come to with the Gas Company for continuing after March 25th on terms of a month's notice.

At the same meeting of the Council a sub-committee of the Works Committee brought up a new scheme for the lighting of the Borough, and recommended that tenders be invited both for electricity or gas. The scheme proposes the use of forty-eight 1,500 c.p. lamps in High Holborn and New Oxford Street; twenty-eight 1,800 c.p. lamps in Kingsway and the High Holborn crossing at Southampton Row; twenty 600 c.p. lamps in Tottenham Court Road; four hundred and five 400 c.p. lamps in seventeen streets; forty-eight 300 c.p. lamps, thirty-seven 180 c.p. lamps, and 1,390 90 c.p. lamps in the remaining streets, the total candle-power amounting to 404,160.

When this report was brought up, it was found that it had not been before the Works Committee, according to the Standing Orders, and after a few minutes' discussion it was referred back in order that the Works Committee should consider a report upon it.

Metal Filament Lamp Tests.—The Westminster Testing Laboratory (York Mansions, York Street, Westminster) inform us that they have completed a series of life tests of fifteen makes of metal filament lamps. Full results are contained in a bound volume, on sale by the Laboratory at the price of £2 12s. 6d. for the first copy and £1 1s. for additional copies.

GAS v. ELECTRICITY IN DUBLIN

THE above subject was discussed by the Dublin section of the Institution of Electrical Engineers on February 9th. Mr. W. TATLOW said that the price of gas in Dublin had recently been reduced, but that the illuminating quality had also been reduced, so that the cost of lighting was now actually greater. The calorific value was now 486 B.Th.U. per cu. ft. For heating, taking gas at 3s. per 1,000 cu. ft., coke at 20s. per ton, and electricity at 1¼d. per unit, the relative number of B.Th.U. obtainable for one penny were: gas, 13,475; coke, 130,700; electricity, 2,720. With electricity, however, the heat could be much more efficiently utilised. As regards lighting, a Dublin hospital had recently replaced incandescent gas burners by 250 35-watt metal filament lamps, and 18 18-watt carbon filament pilot lamps. The relative annual costs were: gas, £155, and electricity £137. Gas cost 3s. 4d. per 1,000 cu. ft., and electricity 3½d. per unit. In another hospital where flat flame burners were replaced by 127 17-watt metal filament lamps and 21 16-watt carbon pilot lamps, the annual gas bill was £240, and the electricity bill is now only £150. A five-foot incandescent burner in Dublin cost 16s. 8d. per 1,000 hours, and a 55-watt metal filament lamp, burning for a similar period, 20s. 8d. There was no gas burner in existence which could compete with a 17-watt metal filament lamp. With regard to power, where a gas engine was running fully loaded all day, it was questionable whether any saving could be made with electricity at 1¼d. and gas at 3s., but where the engine was at times only partially loaded, a considerable saving could be made. Where one large engine was replaced by several motors and the shafting divided up into groups, the saving was very large indeed.

Mr. G. ARCHER (Chief Assistant Engineer, Dublin Corporation) said that flat flame burners in a certain church had been replaced by metal filament lamps of approximately the same candle power. In this case gas cost £20 per annum and electricity only £6 7s. per annum. A large railway engineering shop had used both steam and gas engines, and were now using electric motors only, and were saving something between 30 per cent. and 50 per cent. They found that the steam-engines, when new, were cheaper to run, but after a few years' work the cost rose enormously. Regarding public lighting, they were using 100 c.p. Osrams with very satisfactory results. They obtained an average life of over 1,500 hours.

Mr. W. J. U. SOWTER (Electrical Engineer, Bray) mentioned that in Bray they had not reduced the price of gas, although they had reduced the quality. Although they had no electric power load in Bray, their output was now higher than ever it was before, despite the economy of the metal filament lamp. He could give numerous instances where pounds had been saved by throwing out gas, and he was looking forward to the time when cooking by electricity would be as cheap, or cheaper, than with gas.

Messrs. R. N. Tweedy, G. F. Pilditch, and Wainwright also spoke.

Verband deutscher Elektrotechniker.—The annual meeting of the Verband deutscher Elektrotechniker, the German equivalent of the Institution of Electrical Engineers, will be held this year in Munich during the first fortnight in June. The Elektrotechnische Verein of Munich is arranging to hold an exhibition during that period of domestic, industrial, and agricultural applications of electricity.

The Institution of Electrical Engineers.—The following donations and gifts have been received recently: £200 to the Benevolent Fund from the executors of the late Mr. Gustav Byng, and £21 to the Building Fund from Sir David Salomons. The latter has also presented to the Museum of the Institution a complete Electric Balance by Professor D. E. Hughes, a Door Contact and Bell by Sir Charles Wheatstone, and a Hughes Microphone Model, probably the first ever made. These and other historic electrical apparatus will be on view in the course of a few weeks in a room set aside for the purpose in the basement of the new building.

Obituary.—It is with great regret that we have to record the death, on Wednesday last week, of Mr. Joseph Wetzler, news of which came to hand too late for our last issue. Mr. Wetzler was associated for a very large number of years with electrical journalism in America, first editing the *Electrical World*, and then transferring his services to the old *Electrical Engineer*, which he edited in conjunction with Mr. T. C. Martin until 1898, when that journal was amalgamated with the *Electrical World* of New York. After the amalgamation, Mr. Wetzler started and developed the Electrical Engineer Institute of Correspondence Instruction, and has been settled in this country for several years. His death at the early age of forty-seven will be read of with feelings of regret by the very large circle of friends by whom he was greatly esteemed.

We also regret to hear of the death of Mr. J. McDermott, Managing Director of the Lancashire Electrical Engineering Co., Ltd. Mr. McDermott, who was fifty-three years of age, has been intimately associated with the Electrical Contractors' Association, of which he was a Past President. He was a member of the Conference which met to endeavour to come to an agreement on the wiring question.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

BOILER FEED PUMPS.—The Sun Patent Evaporator Co., Ltd., have sent up a pamphlet describing their patent turbo-pump with renewable liner, specially adapted for boiler feed purposes, with water at any temperature. These can be worked in combination with an ejector which delivers the water to the pump, and avoids the necessity for a first stage of suction impellers. The pump requires no priming, and troubles due to air being carried with the water into the boiler are avoided.

ELECTRIC FURNACES.—A pamphlet from Messrs. Verdon Cutts & Hoult (Town Hall Chambers, 87 Fargate, Sheffield), entitled "Electric Furnaces," dilates upon the advantages of electrical steel manufacture, and gives particulars of an "Electro-Bessemer" process, where the electrical refining is carried out in the same vessel that forms the converter in the ordinary way, avoiding intermediate pouring. Attention is also drawn to the firm's electric welding plants for various classes of work, arc metal-cutting outfits, electrically-heated forges, annealing furnaces, and laboratory furnaces.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

METAL FILAMENT LAMPS.—The accompanying illustration is reproduced from, but does not do justice to, a new show card which Mr. J. Conway Price has just designed for the "Z" Electric Lamp Co., whose lamps, we are informed, are

entirely made, even to the extraction of the metal, in this country. The card, which is effectively printed in eight colours, is 21 in. by 15 in., and the name and address of any agent can be added.

MOTOR STARTERS AND LIFTING MAGNETS.—The second of the series of leaflets published by the Adams Manufacturing Co., Ltd., of Bedford, and describing the latest developments in "Igranic" switchgear, contains prices with illustrations and brief particulars of stator starters for single-phase motors, heavy lifting magnets for engineering works, an automatic change-over switch for switching on an auxiliary supply on the failure of the main supply, and other apparatus.

CONDUIT TUBES AND FITTINGS.—As we go to press we have received the revised "Geekoduct" conduit and accessories list of the General Electric Co. (67 Queen Victoria Street, E.C.). This is particularly complete, and comprises a full range of close-joint brazed and seamless plain conduits of light gauge and heavier gauges in threaded conduit of the welded brazed and seamless varieties, all manufactured at the company's own works at Witton, Birmingham.

The Russian Westinghouse Company.—According to a Reuter telegram from St. Petersburg, the offices of the Westinghouse Company there have been searched by the police, and all the books and documents relating to the St. Petersburg electric tramways have been seized.

The Rating of Electric Automobiles.—An important point to owners of electric cars was raised at the Marylebone Police Court on Monday, when Mr. J. M. Gatti (a director of the Charing Cross, West End, and City Electricity Supply Company) was summoned for keeping a car without a licence. It appears that Mr. Gatti objects to the Treasury regulations, which do not lay down a method of assessing the horse-power of cars other than driven by engines with cylinders, but assume for taxing purposes a minimum of 12 h.p. He contended that his car was sold to him as being of 4½ h.p., and he had originally paid a two-guinea duty. He explained that he had since paid the four-guinea duty under protest, but had refused to pay the Council a "compromise fine." The summons was eventually withdrawn on the understanding that Mr. Gatti's position was in no way prejudiced.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published February 23rd, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications. Names in italics indicate communicators of inventions from abroad.

30,262/09. **Traction Motor Control.** W. WITTEK (Vienna). Automatic gear is described which, when it is switched into circuit, controls the acceleration of the motors according to a predetermined speed-current curve, and also automatically cuts off current and applies the brakes at the correct times in order to follow a predetermined speed-distance diagram. The motor controller is actuated by the movement over contacts of the pointers of an ammeter and a speedometer. Sixteen figures.

66/10. **Storage Batteries.** V. DE KARAVODINE and S. B. APOSTOLOFF (London). Plates are made up with a mixture of lead sulphate and ammonia, which sets hard. The plates are formed in an alkaline bath of ammonium sulphate and ammonia. It is stated that the product is hard, highly porous and conductive, and adheres firmly to the grid.

2,237/10. **Driving of Textile Machinery.** MASCHINENFABRIK OERLIKON (Zürich). An improved automatic mechanism for ring-spinning and twisting frames is described. This not only regulates the speed of the motor in accordance with the different periods of winding the cop, but imparts to the spindles for each stroke of the ring-rail (and more particularly for each stroke during the building of the base of the cop) a variable speed uniformly distributed over the whole length of the layer of thread corresponding at any instant to the diameter of the cop and to the tension of the thread. Six figures.

2,759/10. **Drawn Tungsten Filaments.** BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*). Tungsten powder with a small percentage of carbon is made into a paste with an amalgam binder of bismuth, cadmium, and mercury. This is extruded under pressure through a 40-mil die, and cut into rods about 3 feet long. After baking in a vacuum, the rods are partially sintered in hydrogen. The final sintering is done at a temperature approaching the melting-point of the metal in an atmosphere of hydrogen and nitrogen, and the current through the rods is reduced very gradually during several hours. It has been found that this very gradual cooling results in the tungsten rod being very ductile even at ordinary room temperatures without the necessity for the prolonged mechanical working described in a previous specification. (See ELECTRICAL ENGINEERING, February 16th, 1911, p. 84.)

4,736/10. **Induction Motor.** ELECTRIC CONSTRUCTION Co., LTD., and N. PENSABENE. This patent covers a polyphase induction motor with a self-contained starting resistance and cut-out device, which rotates with the rotor. Coils of resistance strip are wound on edge on the surface of a drum and are connected with the different phases of the rotor, and brushes are arranged so as to be capable of being slid along the surface of the drum so as to cut out the resistance gradually. The brushes preferably rotate with the drum. In an alternative design the brushes slide on rings connected to resistance coils situated within the drum. Four figures.

17,278/10. **Arc Lamp Carbons.** BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) Carbons for flame arc lamps have cores containing about 35 per cent. titanium carbide, 30 per cent. calcium or barium flouride, 15 per cent. cryolite, and 20 per cent. carbon. Such carbons are particularly suitable for the positive electrodes in lamps in which the positive is situated below the negative electrode. A coreless carbon containing these chemicals can also be used.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free. Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: WILLIAMS and STEVENSON [Suspension and connection device] 3,361/10; JOHNSON & PHILLIPS and BROCKIE [Magazine lamps] 4,885/10.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: VANDERVELL [Cable armouring] 11,978/10.

Dynamos, Motors and Transformers: BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Carbon brushes] 3,336/10; SIEMENS BROS. DYNAMO WORKS (*Siemens-Schuckertwerke-Ges.*) [Regulation of power-factor of machines] 10,913/10; BLATHY [Machines] 12,594/10; ALLGEMEINE ELEKTRICITÄTS-GES. [motor control] 15,426/10.

Electric Ignition: MASON [Sparking plugs] 3,161/10; R. BOSCH, 27,168/10.

Electrometallurgy and Electrochemistry: JOHNSON (*Chemische Fabrik Griesheim Elektron*) [Production of long arcs] 5,934/10; PRESSER [Electric welding] 14,859/10; THOMSON [Furnaces] 15,167-8/10; BADISCHE ANILIN & SODA FABRIK [Manufacture of nitrides] 16,368/10.

Heating and Cooking: COOPER (*Boelling*) [Cooking vessel] 17,538/10.

Incandescent Lamps: LICHTWERKE-GES. [Filament supports] 27,710/10.

Instruments and Meters: HANDCOCK and DYKES [Meter system] 3,294/10; LANDI [Electrical speed indicator] 6,256/10; ALLGEMEINE ELEKTRICITÄTS-GES. [Maximum demand meter] 20,446/10.

Switchgear, Fuses, and Fittings: CHILDS and HILL [Controllers] 3,098/10; ASHTON [Lamps on A.-C. systems] 3,518/10; MASCHINENFABRIK OERLIKON [Governors for electrically driven machines] 4,950/10; BARNARD and EDWARDS [Motor controllers] 6,535/10; ADAMS MANUFACTURING Co. (*Cutler Hammer Manufacturing Co., U.S.A.*) [Remote control circuit-breakers] 8,225/10, and [Motor controllers] 11,184/10; DAVIS and SIEBE, GORMAN & Co. [Plug connectors] 8,977/10; GILLIATT and EXCESS INDICATOR Co. [Overload indicators] 18,742/10; MIDGLEY and VANDERVELL [Lamp fittings] 18,916/10; DRUSEIDT [Combined fuse-box and switch] 19,930/10; DENNY and FLOOD [Automatic tumbler switches] 26,737/10; KALAMBA [Plug connectors] 27,248/10.

Traction: COMPAGNIE DE SIGNAUX ELECTRIQUES POUR CHEMINS DE FER [Control of points and signals] 3,199/10.

Miscellaneous: PRATSCHKER [Electric typewriters] 4,359/10; W. WATSON & SONS [Stereoscopic radiographs] 4,506/10; AUB [Electromedical apparatus] 15,634/10; RUTHENBURG [Magnetic separators] 21,031/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: KULKA [Oil-cooled transformers] 2,241/11.

Electric Ignition: BROC [Distributers] 28,590/10.

Switchgear: TRAUS [Lamp switches] 2,520/11; GROB [Regulators] 2,719/11.

Telegraphy, &c.: FESSENDEN [Wireless signalling] 11,154/10 and 2,617/11; SIEMENS & HALSKE A.-G. [Telephone exchanges] 22,013/10; LANGE [Wireless aerials] 2,242/11; FISHER [Signalling] 2,686/11.

Amendment

4,357/10. **Disc Coal-cutter.** F. A. SCOTT and D. MILLER. A disclaiming note has been added to this specification which was abstracted in ELECTRICAL ENGINEERING IN MINES, February 2nd, 1911. The patent covers an improved haulage gear which reduces the height of the machine in that the rope passes at the side of the machine and not below it for forward travel.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

5,789 of March 4th, 1897. **Train-Lighting.** E. J. PRESTON and A. B. GILL. This patent covers a link belt for driving a dynamo from the train axle. It is of vulcanised fibre, and is provided with friction pieces of leather or canvas. Alternatively, it may be constructed with alternate links of leather and vulcanised fibre, the former projecting beyond the latter.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distribution Systems, &c.: BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*). [Automatic cutting-out of faulty sections of distributing systems] 24,180/04.

Dynamos, &c.: W. L. HILDBURGH [Brushes and slip rings for unipolar machines] 22,971/05.

Electric Ignition: ELECTRIC IGNITION Co. and F. H. HALL [H.T. double-armature magnets] 23,058/05.

Electrometallurgy and Electrochemistry: I. J. BRONN [Resistance furnaces] 24,235/02; A. SCHNELLER [Sterilising water by ozone] 24,379/03; J. MILLWARD and W. E. TILLSON [Recovery of tin from scrap] 22,630/05.

Switchgear, &c.: O. L. PEARD [Non-arcing fuse] 19,847/00; F. BRANDT [Accumulator emergency lighting for theatres] 24,369/04.

Telephony, &c.: J. A. GAMBLE [Telephone memorandum] 24,055/03.

Traction: WESTINGHOUSE BRAKE Co. and J. CLOUD [Electromagnetic valve for vacuum brakes] 22,291/01; J. CLOUD [Air-valve for vacuum brakes] 24,352/04.

Miscellaneous: B. SCHWERIN [Electrical drying of peat] 22,301/01; K. A. GUTKNECHT [Electro-pneumatic dispatch apparatus] 24,276/03.

Hosted by Google

THE BRIGHTON CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

THE preliminary programme of the Convention, which is to be held from June 27th to 30th, with Brighton as its headquarters, has now been issued. On Tuesday, June 27th, the Convention is to be opened by his Worship the Mayor of Brighton, Councillor C. Thomas Stanford, at the Royal Pavilion, and Mr. J. Christie, Engineer and Manager, Brighton Electrical Department, will give his Presidential Address, which will be followed by papers and discussions. After luncheon at the Grand Hotel, visits will be paid to works, and a reception and conversazione will be held in the evening at the Royal Pavilion by invitation of the Mayor and Mayoress. On Wednesday, June 28th, the party will travel by special train to Portsmouth, and meet in the Lecture Hall, Municipal College, to hear an address of welcome by the Mayor of Portsmouth, Alderman F. Scott Foster, followed by papers and discussions. Luncheon will be partaken of at the Esplanade Hotel, and visits to works and H.M. Dockyard will be paid in the afternoon. After an evening cruise in the Solent, the return will be made to Brighton by special train. On Thursday, June 29th, papers will be discussed at the Banqueting Room, Royal Pavilion, and visits to works are arranged for the afternoon, after which the annual dinner will be held at the Dome. Friday, June 30th, will be devoted to the annual general meeting for the election of officers and council, and a motor-car run to Arundel. The headquarters will be the Grand Hotel, Brighton, where rooms should be booked at once. Application for accommodation must be made to the hotel. Ladies accompanying the party will receive invitations to the Mayor's reception on Tuesday. On Wednesday arrangements will be made for them to visit places of interest in Portsmouth. On Thursday afternoon a tramway trip will be arranged, and ladies may attend the annual dinner in the evening. Special arrangements are being made for reduced fares, and the Brighton Corporation Golf Links and those of the Southdown Golf Club will be available.

THE MANCHESTER SECTION DINNER

ABOUT 120 members and guests gathered at the Midland Hotel, Manchester, last Friday, on the occasion of the annual dinner of the Manchester Section of the Institution of Electrical Engineers. Mr. J. S. Peck (British Westinghouse Co.), Chairman of the Section, took the chair.

Mr. S. Z. de Ferranti, responding to the toast of the Institution of Electrical Engineers, proposed by Sir T. Thornhill Shann, J.P., referred to the Northern Society of Electrical Engineers, which was not only the predecessor of the present Manchester Section, but also had the distinction of first drawing the attention of the Institution to the importance of provincial organisation. Mr. Ferranti forecasted new activities on the part of the Council which would tend towards the assistance of all sections of the Institution; the Institution should have a care for every interest represented in its ranks. Mr. J. S. Peck, who also responded to the toast, referred to the relations existing between the Council of the Institution and the local sections, and said that since he had sat on the Council the London body had exhibited the greatest desire to do all in their power to develop the local sections and to assist them in every way. Every member of the electrical profession should be a member of the I.E.E.; it was the only organised body that was fighting for the furtherance of electrical interests, and those who were not members were benefiting by the Institution's activities without paying their way.

Mr. W. Cramp, in a light and humorous speech, proposed the toast of The Visitors. This was responded to by Councillor S. W. Royse, J.P., who anticipated that in the very near future there would not be a single cotton-mill that was not electrically driven. The speaker also referred to the present controversy between the Manchester Electricity and Gas Committees; as a member of the former, he complimented Mr. S. L. Pearce on the policy he had pursued, and assured him that as long as he continued on that policy he was certain of their support.

NATIONAL TELEPHONE TRANSFER

AT the half-yearly meeting on Thursday Mr. George Franklin, the Chairman, referring to the position of the Company in relation to the transfer of their undertaking to the State, said that the Company's officers were engaged upon an inventory of the plant upon which the Company's claim would ultimately be founded. As this inventory was being checked by Post Office officials, there were strong hopes that arbitration would not have to be resorted to in order to determine the price to be paid by the Government so far as the main portion of their undertaking was concerned. A difference had arisen, however, with regard to a certain quantity of land, plant and buildings in competitive exchange areas which the Postmaster-General objected to having to purchase, and the Company had also been notified that certain plant had not been constructed in accordance with the specification of the Post Office, as required by the agreement to purchase. The Board had entirely dissented from the Postmaster-General's views with regard to the first objection, and had commenced proceedings before the Railway and Canal Commissioners. As to the second objection, he thought it was likely to result in a very small matter indeed.

LOCAL NOTES

Aberdeen: *Street Lighting.*—An experiment in street lighting by means of metal filament lamps is being carried on in Albyn Place, the lamps being suspended from the span wires of the tramway system. Hitherto this thoroughfare has been lighted by gas, the approximate candle power of each lamp being 40 c.p. Three 400 c.p., two 200 c.p., two 100 c.p., and a number of 50 c.p. lamps have been installed. The experimental lighting will be carried on for one month.

Power Supply.—A contract has been arranged for the supply of electric power to the Great North of Scotland Railway Co. for five years.

Belfast: *Cavehill and Whitewell Tramways.*—The arbitration to determine the price to be paid by the Corporation for the Cavehill and Whitewell tramways has been continued in London during the week. Mr. Stephen Sellon, on behalf of the Company, estimates the value at £37,357, whilst Mr. H. A. Cutler, the Belfast City Surveyor, puts the value at £19,371. There seems to be some difference of opinion as to whether the lines are purchasable on the basis of a "going concern" or not.

Edinburgh: *Tramway Extensions.*—The Tramways Committee are again considering some proposals from companies to extend the tramway system by electric traction.

Halifax: *Tramways Extensions Abandoned.*—The Corporation have decided to abandon the proposed tramways to Mytholmroyd and Sowerby Bridge, which are included in their Bill now before Parliament. In doing so, they propose to call the attention of the Municipal Tramways Association to Standing Order No. 22 of the House of Parliament, which gives a local authority the right to veto any proposed tramway within its area. The Tramways Committee of the Halifax Corporation reiterate the point that has so frequently been made by tramway companies that this Standing Order is a great bar to tramway progress.

Hendon: *Trolley Omnibuses.*—The Council have decided to adopt the system of trolley omnibuses, which has been run experimentally by the Metropolitan Electric Tramways, Ltd., for some months. The agreement is for three years, and if at the end of that time the scheme is found to be unsatisfactory the Company will remove everything at their own cost.

Hull: *Tramway Profits.*—The tramway accounts for 1910-11 will allow of £12,000 being transferred to relief of rates, the net profits being £13,966. There is some difference of opinion among the members of the Tramways Committee as to the wisdom of transferring such a large sum, but a proposal to do so was carried.

Leicester: *Tramways.*—The report upon the tramways for the year to December 31st shows a net balance of £13,734, against £10,669 in the previous year. The tramway power station, which also supplies electricity for power purposes, has 1,880 h.p. of motors connected.

Liverpool: *Power Plant.*—Mr. A. Bromley Holmes, Consulting Engineer to the Electricity Department, has issued a report upon the generating stations and plant. He proposes to make improvements at Lister Drive No. 1 power station by replacing gradually four of the present 700 kw. sets by two turbo-alternators of from 2,500 to 3,000 kw., and correspondingly to increase the condensing arrangements. It is also proposed to put down motor-generators to enable the direct current supply for the auxiliary plant for the No. 2 station to be worked from the turbo-alternators. It is only necessary, however, to deal with the latter proposal in the current year, it not being thought necessary to install any new turbines until the autumn of 1912. By this arrangement it is anticipated that not only will the costs be reduced, but the output will be increased by more than 3,000 kw. without additional boilers or buildings.

Charges for Supply.—Mr. Holmes has also reported upon the charges for electrical energy in Liverpool, and is unable to recommend any drastic alterations in the present tariffs, although he is in favour of extending the rateable value

Hosted by Google

system of charging as much as possible. The reduced output due to metal filament lamps suggests that an increase in the charge for lighting would be justifiable, but as the use of radiators is extending, and a demand for cooking and other domestic services is commencing, Mr. Holmes does not think it would be wise, from a business point of view, to raise the prices at the present time.

London: *L.C.C. Tramways.*—A new electric tramway service from London Bridge to Deptford was inaugurated on Thursday. The length of line is 2¼ miles, and it is to be extended to Greenwich, a total distance of 4 miles.

Loughborough: *Street Lighting.*—It is intended to proceed definitely with the scheme for the conversion of 155 posts, which are on the route of existing mains, from gas to electric lighting.

Sheffield: *New Tramcar Shed.*—The new tramcar shed in Shoreham Street, with accommodation for 96 cars, was opened last week. The cost of the sheds has been £27,500. Being near the centre of the city, a great deal of "waste mileage" will be saved.

Sunderland: *Tramway Receipts.*—It is anticipated that the net profit on the tramways to March 31st will be £3,668 after repaying £10,350 in respect of capital.

Swansea: *Proposed Tramway Purchase.*—It is stated that the Tramways Company have been asked to submit suggested terms as a basis for agreement by which the Corporation might acquire the tramways.

Torquay: *Paignton Tramways.*—Orders have been placed for rails, additional cars, and overhead equipment for extending the tramways to Paignton.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Aberdeen.—A 1,000 kw. continuous current turbo-generator with surface condenser and air pump is required. Particulars from City Electrical Engineer, and tenders by March 9th.

Australia.—The Melbourne Council invite tenders for a battery with boosters and switchboards. Particulars from Messrs. McIlwraith, McEacharn & Co., Billiter Square Buildings, E.C., and tenders by May 8th.

Tenders are invited by the Postmaster-General, Adelaide, by April 19th, for five motor-generators and a switchboard. Particulars, &c., at 72 Victoria Street, Westminster, S.W.

Canada.—An estimate of £226,000 has been submitted to the Ontario Legislature for expenditure by the Government Hydro-Electric Commission in order to complete the Niagara transmission lines.

Eccles.—Tenders are invited by March 20th for a 500 K.V.A. reciprocating engine, single-phase generating set and exciter. Particulars from the Borough Electrical Engineer.

Greenock.—A loan of £22,000 for electrical extensions has been granted subject to the condition that £1,500 per annum is set aside from revenue for reserve.

Kettering.—Tenders are invited for a 350-kw. generating set and a 450-kw. mixed pressure turbo-D.C. generating set with condensing plant. (See an advertisement on another page.)

London: *St. Pancras.*—The Finance Committee of the L.C.C. recommend sanction to a loan of £3,977 for electrical extensions.

Stepney.—The Finance Committee of the L.C.C. recommend sanction to loans amounting to £13,000 for electrical extensions.

Woolwich.—The Finance Committee of the L.C.C. recommend sanction to a loan of £2,000 for electrical purposes.

Middleton.—Tenders are invited by March 8th for a barometric jet condenser. Particulars from the Electrical Engineer.

Northampton.—The Northampton Electric Light & Power Co. is extending its generating plant.

Reigate.—Tenders are invited for two 200 kw. Diesel engine single-phase sets with exciters, pumps, &c.; also for main switchboard. (See an advertisement on another page.)

Scotland.—The Uphall Lighting Committee of the Linlithgow County Council have applied for a loan of £2,000 for electric lighting extensions.

South Africa.—According to the *British and South African Export Gazette*, an electric lighting scheme is being undertaken by the Klerksdorp Municipality.

South Shields.—A Local Government Board inquiry was held last week concerning a loan of £8,960 for extensions to the generating plant. The chief opponents are the North Eastern Railway Co. and Messrs. Smith's Dock Co., who, as large ratepayers, urge that the Corporation can purchase their current more cheaply from the Cleveland & Durham Electric Power Co. than they can generate for themselves. The inquiry was opened a few months back, and adjourned in order to see if an arrangement could be come to. The Corporation, however, acting under expert advice, are of the opinion that it will not be in the interests of the Borough to abandon the proposed scheme of extensions and accept the terms offered by the power company.

Stoke-on-Trent.—The scheme of the Electricity Committee for an expenditure of £60,000 upon the nucleus of a new system of electricity supply for the whole of the Federated area has been referred back. A deputation has been visiting London, Liverpool, Manchester, and Birmingham, and are convinced that it would be cheaper to rearrange the whole of the present equipment at the expenditure mentioned above rather than to spend £20,000, which sum will be necessary to improve the existing plants. If a new system is adopted, Mr. C. H. Yeaman recommends the use of 6,500 volts at 50 cycles, and that to commence with a 1,000-kw. and 1,500-kw. turbo-generator be installed at one of the existing works with trunk mains to connect the other works, together with the necessary sub-station plant.

Watford.—Tenders are invited by March 7th for high and low tension paper insulated cables.

West Hartlepool.—A Local Government Board inquiry was held last week concerning an application for £32,100 for extensions of the municipal electricity undertaking. The proposal is to erect a new generating station, as reported in our columns a short time ago, and to use waste heat from the furnaces of the Seaton Carew Iron Co. Among the opponents to the scheme are the Cleveland and Durham Electric Power Co., who have made an offer which the Corporation contend is equivalent to the exclusive control of the northern part of the town, which includes the docks. The inquiry has been adjourned, owing to the uncertainty of counsel being free to resume within the next few days.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

Aberystwyth.—Isolation Hospital.

Derby.—New Court House.

Elland.—New Secondary School. Tenders are invited for electrical fittings. L. Clegg, Hollywell Green, Halifax.

Glasgow.—Shops and offices in St. Vincent Street.

London.—Buildings in Union Street, Southwark.

Middlesbrough.—Electric Theatre in Newport Road.

Morley.—New Music Hall.

Rochdale.—Considerable alterations at Town Hall.

Swansea.—Electric Theatre, Oxford Street. Messrs. Berens & Franks.—Printing Works, Sydney Street. T. Morgan.—Six houses, Westfa Road. C. Williams.

MISCELLANEOUS

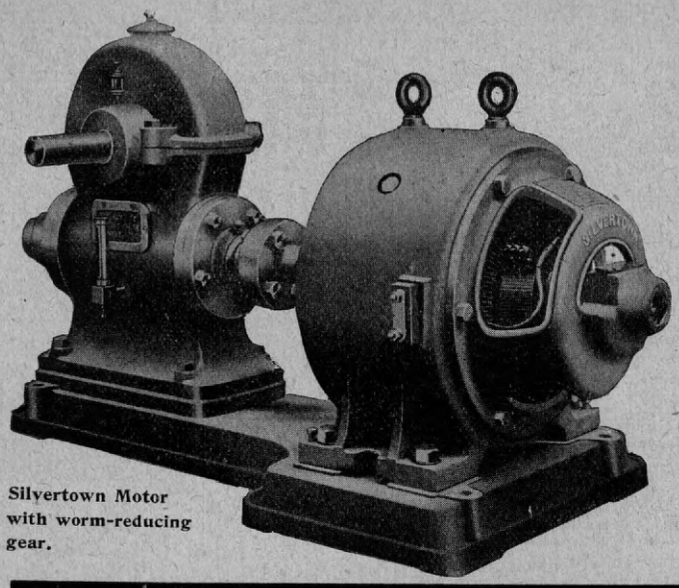
Buenos Aires.—It is stated that a concession for a new tramway from the Tigre to Buenos Aires Port is to be granted to a new company to be formed by the Buenos Aires Port & City Tramway Co.

Chili.—The Chili Electric Tramways and Lighting Co., Ltd., is to undertake extensions of its systems.

Colchester.—Tenders are invited by March 31st for electric lighting fittings, electrical equipment for tramcars, overhead equipment, &c. Particulars from the General Manager.

Dublin.—The Electricity Committee invite tenders for the supply of arc lamp carbons (see an advertisement on another page).

Manchester.—Tramway extensions are to be carried out in the Chorlton district.



Morley.—The Light Railway Commissioners held an inquiry last week into an application by the Corporation for powers to construct a light railway. There was no opposition.

Nottingham.—Tenders are invited for overhead line materials, electrical sundries, &c. Particulars from the Town Clerk, and tenders by March 11th.

Partick.—Tenders are invited by March 6th for cables, cut-outs, meters, incandescent lamps, arc-lamp carbons, &c. Particulars from the Borough Engineer.

Southend.—Electricity is to be substituted for gas lighting on the pier.

APPOINTMENTS AND PERSONAL NOTES

A Principal and Organiser of the Science and Technological Department is wanted for the Crawford Municipal Technical Institute, Cork. Salary £400 per annum. (See an advertisement on another page.)

Mr. W. Wallace, of Stoke-on-Trent, has been appointed Technical Assistant at the Stoke Electricity Works at a salary of £78 per annum, rising to £91.

The salary of Mr. C. A. Baker, Principal Electrical Assistant in the Chief Engineer's Department of the L.C.C., is to be increased from £500 to £550, and to £600 next year.

The salary of Mr. E. Ridley, Electrical and Mechanical Engineer at the chief station of the L.C.C. Fire Brigade, is to be increased to £450 per annum, with two further annual increases of £25.

The salary of Mr. J. Welling, Permanent Way Engineer to the L.C.C. Tramways, is to be increased from £550 to £575 per annum.

The salary of Mr. E. W. Dickinson, Superintendent of Greenwich sub-station, is to be increased from £450 to £475 per annum.

The salary of Mr. E. L. Pope, Resident Electrical Superintendent, Southern Section L.C.C. Tramways, is to be increased from £425 to £450; and that of Mr. T. L. Horn, Resident Electrical Superintendent, Northern Section, from £375 to £400 per annum.

An assistant lecturer in the Electrical Engineering Department of the University of Bristol is required for about five months, at a salary of £3 per week. Apply, Dean of the Faculty, Merchant Venturers' Technical College, Bristol.

The Leicester Electricity Committee have appointed Mr. T. R. Smith, Tramways Engineer, to be Engineer and Manager of the Electricity Department, in addition to his present duties, with an increase in salary from £500 to £600 per annum. Mr. J. E. M. Stewart, Chief Assistant Engineer of the Electric Lighting Department, is to be Assistant Engineer of the Electricity Department at a salary of £350 per annum.

The salary of Mr. G. T. Dickens, Stores Superintendent, L.C.C. Tramways, is to be increased from £300 to £325 per annum, and a similar increase is to be granted to Mr. A. Terry, District Traffic Superintendent Southern Section, L.C.C. Tramways.

Mr. W. Buchanan, formerly Chief Designer to the Electric Construction Co., and recently senior lecturer at Faraday House, London, has been appointed Professor of Electrotechnics at the School of Mines (Transvaal University), Johannesburg. The salary is £1,000 per annum, and Mr. Buchanan will be allowed to engage in consulting work.

Mr. W. Bolton Shaw, formerly Electrical Engineer to the Hulton Colliery Co., Ltd., and more recently connected with Messrs. John Musgrave & Sons, Ltd., as chief turbine designer, is now in practice as a consulting engineer and has opened an office in Irene Chambers, 25 Market Street, Manchester.

A draughtsman acquainted with electrical work is required. (See an advertisement on another page.)

The Acton Electricity Undertaking.—A short discussion took place in the House of Commons on Tuesday upon the motion for the second reading of the Metropolitan Electric Supply Company's Bill, which seeks to acquire the Acton electricity undertaking. Mr. Parker, the Member for Halifax, and Mr. Pointer, Member for the Attercliffe Division of Sheffield, argued that the Council's undertaking is just on the borderline of success, and that to transfer it now would be against the best interests of the ratepayers. Further, the whole matter had been done at the bidding of one or two persons on the Council. Mr. Tennant, on behalf of the Board of Trade, said that there should be no objection to the Bill being read a second time, and sent to a Committee to be dealt with. Eventually the Bill was read a second time by a majority of 15.

Proposed Gathering of Old Ferranti Men.—A notice reached us too late for insertion in our last issue that old Ferranti men propose to hold a dinner in the near future, at which Mr. S. Z. de Ferranti will be the guest of the evening. We understand that a committee has been formed to bring the matter to the notice of their former colleagues. The committee includes the names of Messrs. A. B. Anderson, C. P. Sparks, W. H. Kolle, Chas. Day, G. del Rivo, G. W. Partridge, A. E. Hadley, and Haydn Harrison. The date of the proposed gathering is not yet fixed, but it is intended that it shall take place during Mr. Ferranti's term of office as President of the I.E.E. Ferranti men who see this paragraph are asked to bring the matter to the notice of others with whom they are acquainted, and to send their names to Mr. W. E. Warrilow, Selwyn Avenue, Watford, who is acting as Hon. Sec., and who will be pleased to forward full particulars.

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night was £57 5s. to £57 10s. per ton (last week, £57 10s. to £57 15s.).

Royal Appointment.—Messrs. A. P. Lundberg & Sons, 477 to 487 Liverpool Road, Islington, N., have received the honour of an Appointment as Electrical Accessories Manufacturers to H.M. King George V. The firm held a similar appointment to his late Majesty King Edward VII.

Chillingworth Gear Cases.—We are informed that R. Chillingworth, of Nurnberg, has made arrangements for the sale of the Chillingworth patent pressed steel gear cases in the United Kingdom, and for export therefrom, to be handled by the British Thomson-Houston Co., Ltd., exclusively. All inquiries hitherto sent to R. Chillingworth at Nurnberg, or to his representatives in the United Kingdom, should in future be referred to the British Thomson-Houston Co., Ltd., Rugby, or to their branch offices.

"EOA" Specialities.—The extension of the business of the Electric & Ordnance Accessories Co., Ltd., in Lancashire and Yorkshire has necessitated the doubling of the office accommodation at 196 Deansgate, Manchester. Mr. J. Booker is the company's representative.

Plant for Sale.—The Electricity Committee of the Walsall Corporation have a quantity of steam and electrical plant for sale. (See an advertisement on another page.)

Bankruptcies.—The liabilities in the bankruptcy of V. G. Birkett, electrical engineer, 38 Park Row, Bristol, are put at £214, with a deficiency of £113. The public examination is to-morrow, March 3rd.

The last day for receiving proofs in the bankruptcy of J. W. Barnet, electrical engineer, 25 Waterloo Road, Burslem, is March 9th. The trustee is F. T. Halcomb, King Street, Newcastle, Staffs.

The trustee in the bankruptcy of J. D. Morton, electrical engineer, Nettleton Road, Mirfield, Yorks, has been released.

Telegraph Traffic.—There is no news with regard to the French West India system, and the New Caledonia cable is still down. No doubt the steamer of the Pacific Cable Board will be chartered if possible to put this section in order. The cable between Zante and Corfu of the Eastern Telegraph Co. failed on the 26th ult. The El Arich route has continued down for a longer period than usual, as repairs were only effected on 27th ult., the line having to be overhauled in two or three places. The *via* Hanekine route was down on the 22nd ult. between Constantinople and Ismid. On the 25th ult., the Indo-European Telegraph Co. effected the restoration of their route, but it again broke between Kertch and Soukhoum Kale.

The Telephone System.—A Conference of Municipal Authorities, convened by the Glasgow Corporation, was held in London on Monday, when the proposed abolition of the limited service system of charging for telephones was protested against. The deputation afterwards waited upon the Postmaster-General, who said he was willing to arrange for a public inquiry after the National Telephone Company's business had been taken over and the Post Office had fixed their rates for telephone service.

Wireless Telegraph Notes.—A *Central News* cable from San Francisco states that wireless communication has been established between that city and Chosi Shimosa on the Japanese coast, a distance of 5,700 miles. The messages were passed with one relay, for which purpose a steamer of the Pacific Mail Co. was used.

A wireless telegraph installation has just been completed at the Rosyth naval base.

At the coming Imperial Conference, reference will be made to the linking up of the colonies by wireless telegraphy. It is suggested that Canada and New Zealand could communicate with each other by means of a powerful intermediate station on one of the South Pacific islands. The Admiralty are said to be particularly interested in the scheme.

As a result of the successful experiments with wireless apparatus on submarines, several boats are to be fitted with apparatus which has been especially designed for the purpose.

Wireless telegraph communication has been established in Russia between Nicolaievsk-on-Amur and Kamchatka, a distance of 800 miles. During the winter months there is no postal service to the latter.

Hosted by Google

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Notting Hill Electric Lighting Co.—The net profit for 1910 was £12,905, after providing for depreciation, renewal, and reserve fund, &c. A bonus of 2 per cent. is declared upon the preference shares, and a dividend of 6 per cent. with a bonus of 2 per cent. on the ordinary shares, together with a distribution of £5 per share on the founders' shares. A scheme for rearranging the capital of the company has been formulated.

London Electric Railway Co.—An issue of £1,250,000 4 per cent. preference stock is to be made at 83.

Welsbach Incandescent Gas Light Co.—A provisional agreement has been entered into with the Deutsche Gasglühlicht Aktiengesellschaft (Auergesellschaft) of Berlin to promote a new company in England to acquire the present English Welsbach Company. The purchase price is to be £440,000, made up as follows: £100,000 in cash, £240,000 in 4½ per cent. debentures, and £100,000 in new shares.

Yorkshire Electric Power Co.—At the half-yearly meeting last week Mr. A. G. Lupton, chairman of the company, had a good deal to say with regard to the obstruction of local authorities towards the extension of electric power supply by power companies.

Newcastle-upon-Tyne Electric Supply Co.—A dividend of 4 per cent. for 1910 on the ordinary shares.

London Electric Supply Corporation.—At the annual meeting last week Mr. R. Stewart Bain, Managing Director, after referring to the new contract with the L.B. & S.C. Railway for 17 years, stated that the London Electric Railway Company's Bill, and also that of the Metropolitan District Railway Co., would be strenuously opposed, as they affected nearly all the supply undertakings in London. The Bills in question provide for the supply of electrical energy from the Lot's Road power station to all the tube railways in London.

Chelsea Electricity Supply Co.—The accounts for 1910 show a net profit of £38,897, after placing £12,782 to renewals and depreciation, and writing £1,089 off cost of extinction of founders' shares. A final dividend on the ordinary shares, making 5 per cent. per annum, is declared, carrying forward £2,298.

Companies Struck off Register.—The names of the following have been struck off the Register of Joint Stock Companies: General Electric Inspection Co., International Telescriptor Syndicate, Simplified Underground Conductor Co., and Telephonic Bell Push Syndicate.

County of London Electric Supply Co.—Dividend at the rate of 6 per cent. per annum for the half-year on the ordinary shares, making 5 per cent. for 1910. Depreciation has been credited with £20,000.

The Waste Heat & Gas Electrical Generating Stations.—After transferring £7,000 to reserve, there is a balance of £18,518, and a dividend of 8 per cent. per annum for 1910 is recommended, carrying forward £6,048.

SUMMARY

Details are given of a 2,000-k.v.a. turbo-alternator which the Electric Construction Co. have recently supplied to the Corporation of Wolverhampton. (Page 119.)

An interpole motor with the field system carried on ball bearings so as to provide a simple means of measuring the torque has been constructed for the new Technical Institute, Dundee. A search coil on the armature is connected to slip-rings and a special timing device. (Page 120.)

Our monthly article on new electrical supplies and accessories contains illustrated descriptions of some special accessories designed in accordance with the Home Office rules and recommendations for factories. A new enclosed three-pole circuit-breaker is also described, and illustrations are given of some new forms of electric heater. (Page 121.)

A new paralleling volt-meter for alternating current has been introduced under the name of the "Paller." (Page 122.)

At a meeting of the Röntgen Society last week, Mr. A. A. Campbell Swinton made some interesting experiments with a 10,000-volt storage battery consisting of 4,800 Planté cells. (Page 123.)

Steam consumption tests of a 6,000-kw. Brown-Boveri turbo-alternator at the Dunston power-house of the Newcastle-upon-Tyne Electric Supply Co. have given figures as low as 11·8 lb. per kw.-hour on full load. (Page 123.)

The Papers on high-tension transmission by Mr. W. G. Taylor and Messrs. R. Borlase Matthews and C. T. Wilkinson have been further discussed at the Institution of Electrical Engineers in London. Mr. C. P. Sparks thought that pressures higher than 20,000 volts would be required in this country, but he did not favour the high-tension direct-current system. Mr. W. B. Woodhouse urged that the Institution should take up the question of wayleaves. The use of steel poles of tubular construction was advocated by Mr. E. J. Fox, and Mr. A. Jacob called attention to the extended use of aluminium for overhead conductors. Mr. E. H. Rayner referred to the safeguard afforded by the corona discharge if the line were worked just below the critical pressure. The practice of transmission systems in California was described by Mr. F. V. T. Lee. (Page 124.)

An interesting Paper by Mr. A. G. Collis, read before the South Wales Institute of Engineers, contained some oscillograph records of current and pressure at the moment of breaking circuit by various forms of switch and circuit breaker. A number of well-known authorities on switchgear contributed to the discussion. (Page 125.)

Certain suggestions for uniformity in symbols formulated by the unofficial Conference of the International Electrotechnical Commission at Brussels are published. (Page 126.)

Mr. W. W. Frith, in a recent Paper before the Newcastle Local Section of the Institution of Electrical Engineers, discussed the phase differences between synchronous motors and generators. (Page 127.)

Some new electrical effects have recently been introduced into the Drury Lane pantomime. (Page 129.)

Among the specifications published by the Patent Office on Thursday last was one by the British Thomson-Houston Co. for a process of manufacturing carbon brushes and electrodes of great density and high conductivity. The carbon is impregnated with pitch, and then fired at a high temperature. An improved feeding mechanism for a magazine flame arc lamp is covered by Johnson & Phillips, Ltd. The arc is not extinguished on changing over to a fresh pair of carbons. Felten & Guilleaume Lahmeyer-Werke

Hosted by Google

A.-G. have abandoned a patent covering the introduction of phosphorous nitride into lamp bulbs to prevent disintegration of the filaments. (Page 128.)

AT an extraordinary general meeting on Thursday, the scheme for forming a new English Welsbach Co., in which the German Welsbach Co. will have the controlling interest, was passed. Some interest is created as to the future of the metal filament lamp which the English Welsbach Co. now sells. (Page 129.)

IN an address delivered at the Municipal Technical School, Birmingham, Mr. M. Railing emphasised the importance of a broad training for engineers, including commercial and business knowledge, and spoke in support of a protective tariff to protect home industries. (Page 129.)

THE Chairman of the Hull Tramways Committee has resigned as a protest against allocating large sums from the profits for relief of rates.—At Sheffield the amount transferred from tramway profits to relief of rates has been reduced by over £3,000.—An unsuccessful attempt has been made to get the Westinghouse Company struck off the list of tenderers to the Manchester Corporation.—The Board of Trade have been asked to appoint an arbitrator to decide the difference between the Manchester Tramways Committee and its employees. (Page 130.)

A 1,500-KW. generating set is required at Burnley; 1,000-kw. turbo-alternator, &c., at Rotherham; a battery and booster at Norwich; feeders at Kendal; and electrical supplies at Bolton. Additional plant is also to be installed at Rochdale; and the following loans are to be taken up: Dublin, £128,000; Felixstowe, £2,935; Ipswich, £17,000; Leek, £4,000; Liverpool, £25,000; and Bermondsey, £5,000. (Page 131.)

A 15 PER CENT. dividend is recommended by Messrs. W. T. Henley's Telegraph Works Co., Ltd.; 5 per cent. by the Metropolitan Electric Supply Co.; 6 per cent. by the County of London Electric Supply Co.; and 8s. per share by the City of London Electric Lighting Co. (Page 131.)

THE British Radio-Telegraph & Telephone Co. do not intend to appeal in the Marconi patent case. (Page 132.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, MARCH 9TH.

Institution of Electrical Engineers.

8 p.m. "The Laying and Maintenance of Transmission Cables," by C. Vernier.

Institution of Electrical Engineers: Dublin Section.

8.20 p.m. At Royal College of Science.

FRIDAY, MARCH 10TH.

Physical Society.

8 p.m. At Imperial College of Science. (1) "Note on an Electrical Trevelyan Rocker," by Dr. W. H. Eccles. (2) "Notes on the Tilted Gold Leaf Electroscope," by Dr. G. W. C. Kaye.

SATURDAY, MARCH 11TH.

Birmingham and District Electric Club.

7 p.m. At 49 Newhall Street, Birmingham. "Small Electric Lighting Plants," by C. Bell Walker.

MONDAY, MARCH 13TH.

Royal Society of Arts.

8 p.m. Cantor Lecture II.: "Applications of Electric Heating," by Prof. J. A. Fleming, F.R.S.

TUESDAY, MARCH 14TH.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. At the University. "Electricity Meters," by H. A. Ratcliff and A. E. Moore.

Institution of Electrical Engineers: Glasgow Section.

8 p.m. At 207 Bath Street, Glasgow.

Illuminating Engineering Society.

8 p.m. At Royal Society of Arts. Resumed discussion on "School Lighting."

Institution of Civil Engineers.

8 p.m. At 25 Great George Street, Westminster. "The Electrification of a Portion of the Suburban System of the L.B. & S.C. Railway."

WEDNESDAY, MARCH 15TH.

Association of Mining Electrical Engineers.

7.30 p.m. *Newcastle Branch.* At Milburn House, Newcastle. (1) "Oils for Transformers and Switches," by G. W. Humphrey. (2) "Conditions Specially Relative to Small Colliery Installations," by T. Thomson.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. At Victoria Embankment. "Exhaust Steam Turbines," by R. C. Plowman and E. F. Hetherington.

WELSBACH-AUR LAMP—I wonder where I come in: perhaps cousin Osram will ask me to join him and the others, same as he did that Dutch boy Phil. (*See page* 129.)

Hosted by Google

A NEW DESIGN OF TURBO-ALTERNATOR

A LARGE new three-phase turbo-alternator has recently been constructed by the Electric Construction Co., Ltd., to the order of the Wolverhampton Corporation. The machine presents several interesting features of design, particularly in the construction of the rotor centre and in the scheme of ventilation, and is designed to give 2,000 K.V.A. at 0·85 power factor, 6,600 volts, 50 periods, 1,500 r.p.m.; it has also to give 3,000 K.V.A. continuously without excessive heating. Photographs showing the general appearance of the stator and rotor are given in Figs. 1 and 2, and full details of the construction can be seen in Fig. 3.

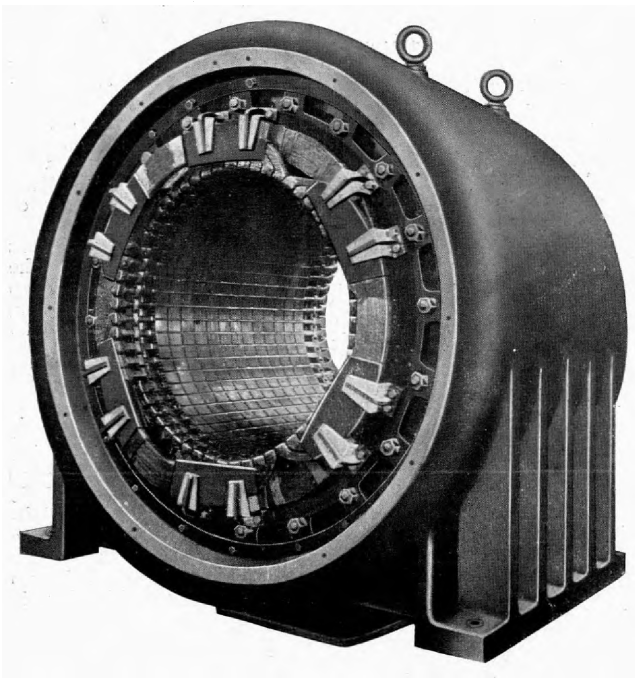

Fig. 1.—View of Stator with End Shields Removed.

The most important feature of the machine is its rotor construction, the centre being made from a solid block of steel. As will be seen from the figures, the rotor winding consists of four coils per pole distributed in slots parallel to the pole axis. This arrangement obviates the necessity for deforming the coils, as is usually the case with former wound coils when placed in radial slots. The end connections of the coils are also embedded in slots which lie in planes at right angles to the shaft. The end connections of the outside coil of each pole are held in position by gun-metal brackets. The stator winding is of the "bow" type, the coils lying in two different planes. This type of winding lends itself to a very rigid method of clamping, as will be seen from Fig. 3.

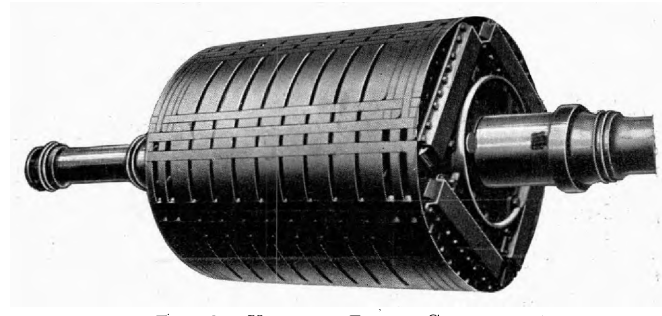

Fig. 2.—View of Rotor Complete.

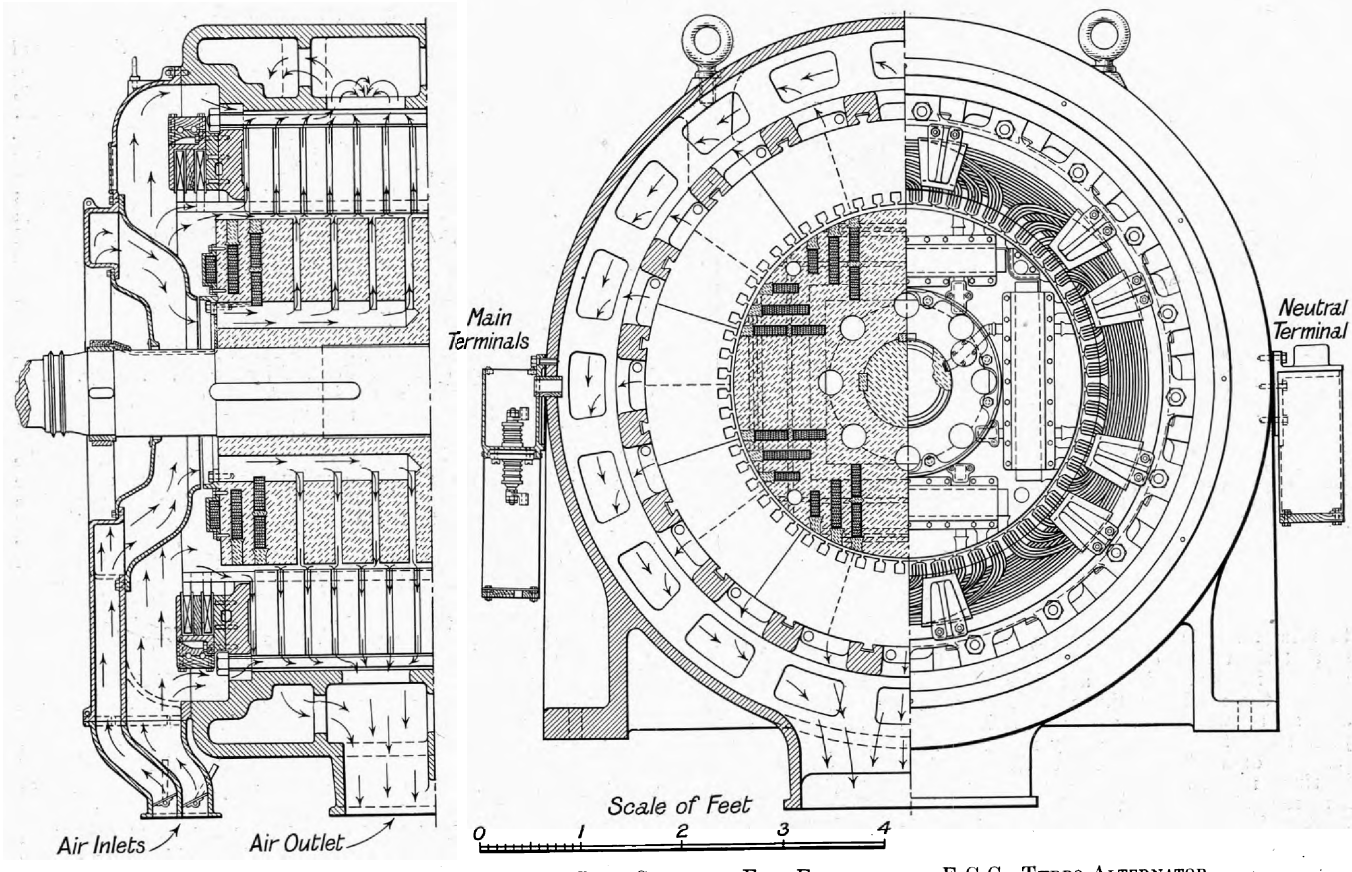
The machine is arranged for forced ventilation. The inlet pipes are at each end of the machine, and each



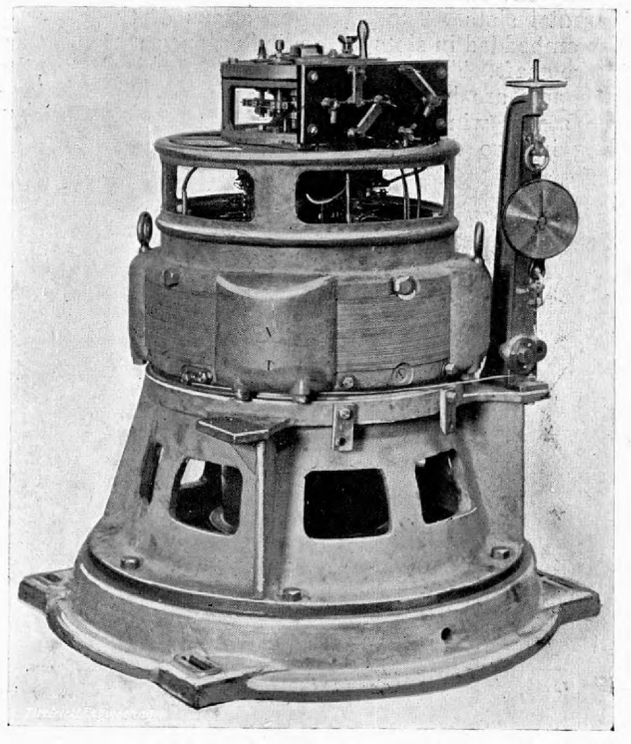


Fig. 3.—Half Longitudinal Section and Part Sectional End Elevation of E.C.C. Turbo-Alternator.

Hosted by Google

is subdivided into two different channels, one taking the air into an annular chamber, which delivers it through round longitudinal holes in the rotor and thence to the stator by means of suitable radial air ducts. The other channel is mainly intended to convey the air for cooling the stator windings. The air passing through these two channels meets at the back of the machine, cooling the iron and coming away through the outlet pipe below the stator. Each of the channels contains an air valve, which allows of proper regulation, so that extravagant expenditure of power for ventilation purposes may be avoided. The quantity of air passing through the machine under the heaviest condition of load is estimated to be 10,000 cubic feet per minute.

MACHINES FOR EDUCATIONAL PURPOSES

At the invitation of the J.-L. Manufacturing Co., Ltd., of Southall, Middlesex, we have inspected a machine of novel construction, built by them for experimental purposes to the requirements of Mr. R. D. Archibald, of the new Technical Institute, Dundee. The machine is a four-pole, 400-volt, compound-wound variable-speed D.C. motor, provided with interpoles, and designed for a continuous output of 10 b.h.p. at from 300 to 1,000 r.p.m. As shown in the illustration, it stands on a heavy cast-iron circular bedplate, and is arranged vertically with the pulley below to render the commutator, brushgear, and all connections easily accessible. The base is a casting in the form of a truncated cone supporting the laminated yoke and poles on a ball race, which takes both weight and side stresses. The field system, therefore, is free

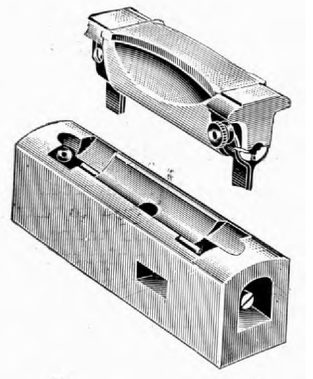
10-h.p. Interpole Motor.

to rotate, but is attached to a spring balance by a steel cord so that the torque can be measured. This cord lies in a groove so that its centre is at a radius of 1·05 ft. from the centre line of the machine; this measurement is equal to $33/10\pi$ ft., and so allows of easy determination of the h.p. The main poles and interpoles are easily removable from the yoke for the purpose of exchanging coils. The armature revolves on ball bearings round a steel spindle, firmly secured to the bedplate. A search coil spanning the winding pitch is provided in the armature and is connected to slip rings. This coil is to enable investigations of the field form to be made, either with an oscillograph or by plotting a curve from instantaneous readings. The latter are obtainable by means of a contact-maker and a variable timing arrangement by which both the time of contact and the position of the coil at time of contact are variable through the whole range. The commutator is provided with box-type brush-holders, with provision for using varying widths of carbons. All parts of the machine are easily accessible. The armature may be removed without disturbing the field, and provision is made for removing the ball bearings intact. Similarly, the entire field brushgear and base may be removed without disturbing the armature. Special attention has been given to the terminal arrangements. The armature, shunt field, series field, and interpoles have their ends joined up to a terminal slab, and the connections required are made by links. We understand that this machine will be regularly employed for driving a generator. Under test as a motor with a load of 10 b.h.p. at its lowest speed of 300 r.p.m., the efficiency proved to be 86 per cent. The company have also supplied a special motor-generator for the Dundee Institute. This comprises two series-wound machines, both of which may be used as generators or motors as required. One machine has a field system carried in ball-bearing pedestals and fitted with a torque lever and spring balance, as in the case above. Removable covers with radiating gills and covers of the ordinary ventilated pattern are also provided, so that the effect of various degrees of enclosure on the rating may be studied.

Having inspected the above machine, our representative was conducted over the works by Mr. T. L. Reed Cooper, the managing director, and the admirable card system of shop records and storekeeping in use was explained. An increasing business is being done by the firm in motor-generators for cinematograph projectors; the laminated field, ball bearings, and flexible couplings employed are claimed to result in machines of smaller size and higher efficiency than those of other makes. A number of variable-speed motors, with and without interpoles, were also in hand. The firm employ, in certain cases, the patent Lundell brush for resistance commutation, in which the brush consists of two parts inclined so as practically to meet at the surface of the commutator. The leading brush is of high-conductivity carbon, while the rear brush is of high-resistance carbon. In a new box-type brush-holder for single carbons, there are two springs, a coiled spring to exert the main pressure, and a short, flexible strip spring to take up irregularities in the commutator, &c. This combination is claimed to eliminate chattering.

Siemens Bros.' Supply Department.—The Supplies Department of Messrs. Siemens Bros. Dynamo Works, Ltd. (39 Upper Thames Street, E.C.) held a highly successful smoking concert last Friday at Stone's Restaurant, Ludgate Circus. The concert was largely attended by members of the staff and their friends. The programme was well selected and very entertaining, and a most enjoyable evening was spent by those present.

Tramways & Light Railways Association.—At the annual general meeting on February 17th, the following were elected Vice-Presidents:—Lord Arthur Butler, Mr. Harmood-Banner, M.P., Mr. J. M. Henderson, M.P., and Councillor Jas. H. Rogers, Chairman, Newcastle-on-Tyne Tramways Committee. To fill vacancies on the Council the following were elected:—Mr. R. L. Acland, Manager, Chesterfield Corporation Tramways; Mr. W. Clough, Manager, Bury Corporation Tramways; Mr. C. H. Dade, Secretary, British Electrical Federation, Ltd.; Alderman Wm. Ivey, West Ham Corporation Tramways; and Mr. John Kennedy, Parliamentary Agent. A deputation from the Association waited upon the President of the Board of Trade on February 16th, and discussed certain points in relation to reform of tramway legislation.



Electric Smelting in Norway.—The following information, supplied for the *Board of Trade Journal* by Mr. E. F. Gray, H.M. Consul at Christiania, is of interest. A company has been formed, under the name of the "Stavanger Electro-Staalverk A/s," with a capital of £25,000, for the purpose of utilising scrap iron and steel from broken-up vessels, workshops, &c., for the electrical production of high-quality steel. Works are to be erected near Stavanger, in Ryfylke, where the company has secured water-power to the value of 10,000 h.p. In view of the increasing import—now amounting to about 10,000 tons per annum—into Stavanger of tin plates for the fish canning industry, the establishment of tin-plate rolling works may be considered later. The annual output of the steel works is estimated at 1,400 tons of high grade steel billets, and 600 tons of cast steel. The Tinfos paper mills have turned over the electric iron ore smelting undertaking at Notodden to a newly-formed company named the "Tinfos Jernverk, A/s," Notodden, with a capital of about £55,500. A new undertaking for the electrical smelting of iron, known as the "A/s Arendals, Fossekompagni," has been established at Arendal, with a capital of £233,300. It is stated to own the Böile Foss, near Arendal, a waterfall capable of affording 30,000 h.p. The company will use the Swedish Grönwall process, and has also acquired ore deposits near Arendal. The Ilen Smelting Works, of Trondhjem, have commenced using a furnace of 1,000 h.p., chiefly for copper smelting, with an estimated capacity of 2,000 tons per annum. A 3,000-h.p. furnace for iron smelting, capable of producing 9,000 tons per annum, is expected to start work shortly. A consignment of 25 tons of pure copper produced by electric smelting has recently been exported from the Birtavarra mines near Lyngör. The "A/s Kristianssands Nikkelraffineringsverk," Christiansand, is about to undertake the electric smelting and refining of nickel and copper.

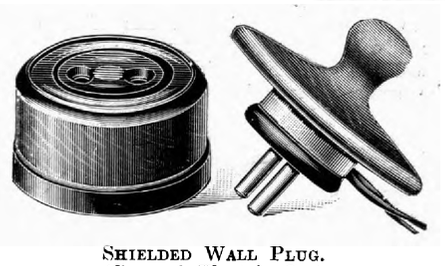
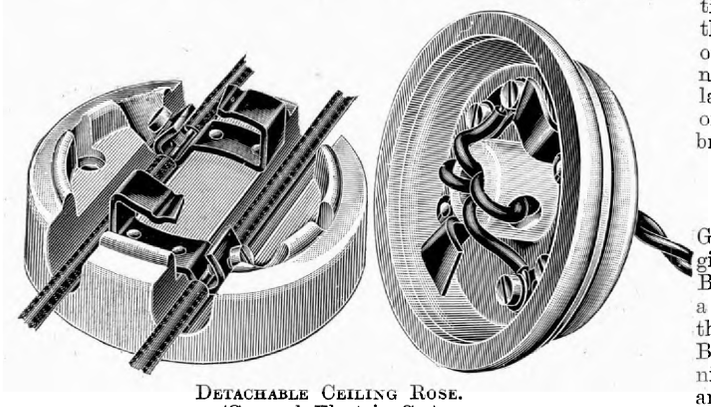
NEW ELECTRICAL SUPPLIES AND ACCESSORIES



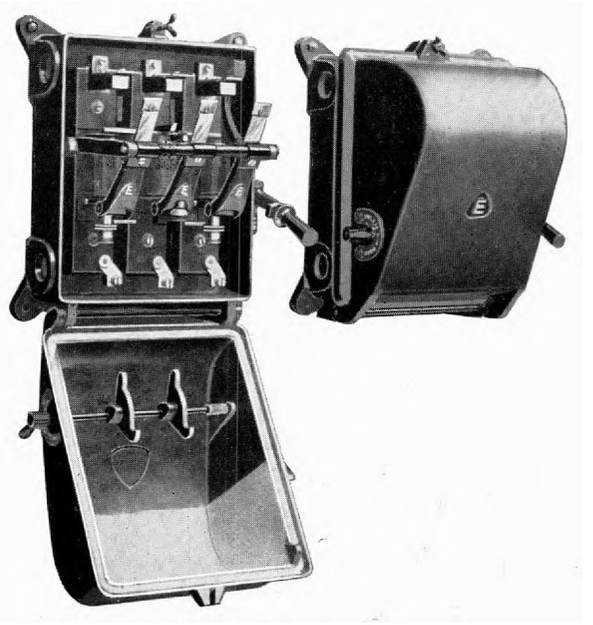
Switchgear.

A new catalogue of accessories, specially designed in accordance with the rules and recommendations of the Home Office under the Factory Acts, and thus embodying the results of the experience of H.M. Electrical Inspector of Factories in the investigation of causes of accidents, has just been issued by the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.) with the attractive inscription on the cover, "Shield your workpeople by using G.E.C. 'Home Office' shock-proof accessories." These rules and recommendations allow for two methods of protection :—providing parts liable to be touched with shields, handles, or covers of insulating material, and



Protected Fuse-holder with China Base.
(General Electric Co.)

efficiently "earthing" all such parts that do not carry current. Believing the first to be a better method, the General Electric Co. have devoted special attention thereto, but where constructional or other difficulties have prevented the adoption of the insulating, earthing facilities have been provided. One of the features of the list is the shielded fuse-holder illustrated here. Besides in the china-base form, these fuse-holders are also utilised in a type of complete fuseboard, which embodies H.M. Inspector's suggestion that terminals of fuseboards and 'bus-bars should be recessed or ranged so that they cannot be inadvertently touched by the operator.



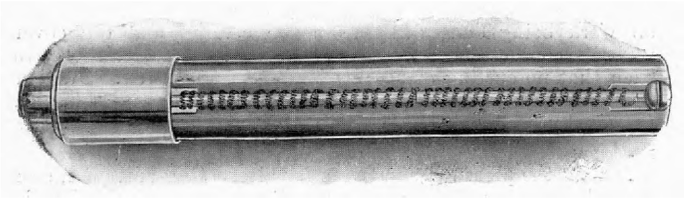
Shielded Wall Plug.
(General Electric Co.)

Detachable Ceiling Rose.
(General Electric Co.)

Another figure illustrates one of the series of shielded wall-plugs, with the wires entering at the side so that the hand cannot touch the flexible when inserting or withdrawing the plug. Attention should also be drawn to the detachable ceiling rose shown in the third illustration, which permits of all work being done away from the ceiling, and the cover with its contacts then clipped into place. The terminals are such that no cutting of the main cables is required. Further special apparatus includes standard, bench and portable lamps, principally of insulating material, and with no metal parts exposed.

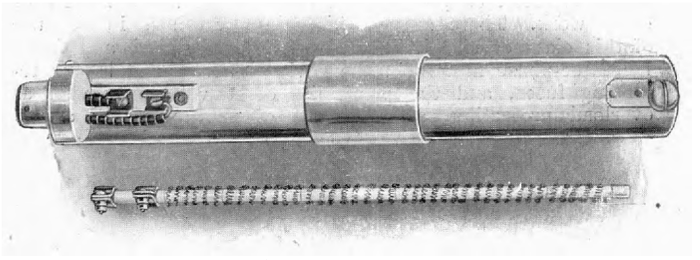
Among the pieces of apparatus for alternating current motor control recently introduced by George Ellison (Victoria Works, 17 and 18 Warstone Lane, Birmingham) is the three-pole totally enclosed circuit-breaker illustrated here. This is known as the "mill" type, and although primarily intended for motor circuits, can, of course, be used for house service or other work. There are considerable advantages in the use of this class of circuit in place of a plain switch and fuses for three-phase motors in the saving of time and labour replacing fuses, and the possibility of no-voltage as well as overload protection, and the use of the apparatus as an

Mill Type Three-pole A.-C. Circuit Breaker
(George Ellison).



emergency switch by intercepting the no-voltage release circuit. The breaker is at present made in two three-pole sizes for 50 and 100 amperes, but single- and double-pole patterns will soon also be on the market. They are quite watertight, and the cover is hinged and interlocked, so that it cannot be opened if the breaker is closed, and the breaker cannot be closed if the cover is open. There are two handles, one on the right for closing the breaker and a small one on the left for tripping the breaker, or, by turning in the opposite direction, for holding down by hand the overload releases to prevent them operating *until* the motor has got up to speed. The overload releases can be set to operate at any load between normal full load and 80 per cent. overload. Adjustable time-lags or retarders can be fitted if the load is a fluctuating one subject to heavy peaks of short duration that open the breaker unnecessarily.

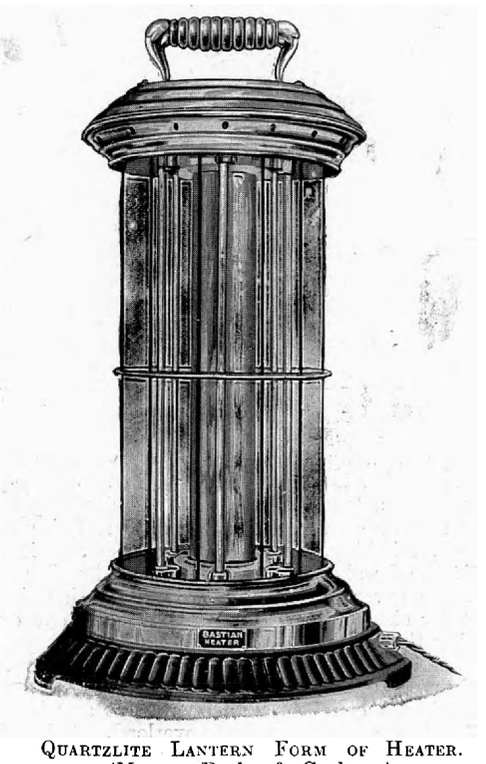
Electric Heating.



We are now able, through the courtesy of Messrs. Drake & Gorham, Ltd. (66 Victoria Street, Westminster, S.W.), to give an illustration of the new vertical or "lantern" form of Bastian Quartzlite heater, to which we briefly referred on a previous occasion. The heating elements are similar to those in the now well-known horizontal or rat-trap form of Bastian Quartzlite heater. The heater is of good appearance, nickel plated all over except for the black handle and base, and is by no means expensive. Messrs. Drake & Gorham are also putting on the market a new form of Quartzlite element, which can be employed to replace radiator lamps in radiators fitted with ordinary lamp-holders. The heating element is rather different from the older pattern, and has both terminals at one end, with a wire leading up inside the quartz tube and a spiral of resistance wire outside the tube. Only the actual glower ever wants renewing, and this is

Hosted by Google

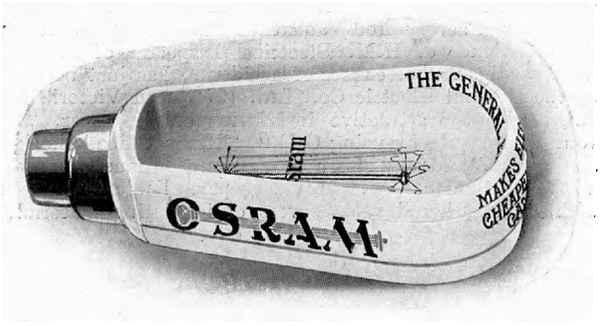
lower in cost than the ordinary lamp of the same capacity (250 watts). The arrangement of the reflector and the direct



New "Quartzlite Exchange Type" Heater to Replace Carbon Radiator Lamps.

Element Removed from Reflector.
(Messrs. Drake & Gorham.)

contact of the glower with the air give a powerful heating effect. It is advisable to fit a wire guard across the front



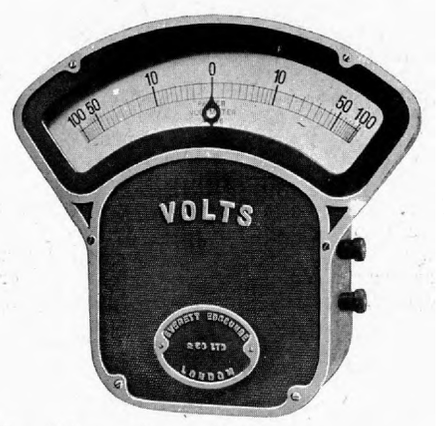
Quartzlite Lantern Form of Heater.
(Messrs. Drake & Gorham.)

of the heater to prevent dresses, &c., coming into contact with the hot glowers.

Messrs. Siemens Brothers Dynamo Works, Ltd., Tyssen Street, Dalston, London, N.E., beg to remind their friends in the trade that owing to the already considerable numbers of orders and request for designs of complete decorative schemes which they have already received, it will be advisable to apply early for any such designs that may be required. Orders and inquiries will be dealt with in the strict rotation in which they are received, and should consequently be placed as early as is convenient. It will be noticed that Messrs. Siemens are prepared to quote for complete Coronation illumination schemes, but, as is their invariable practice, they are arranging to sublet all the wiring and erection among contractors, who will doubtless appreciate such an attitude, which cannot fail to be of assistance to them. Every contractor should apply for copy of the Siemens Coronation Decoration List, which, we understand, will be supplied to any member of the trade on receipt of application accompanied by trade cards.

SMOKERS AND OSRAM LAMPS

The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), have designed a remarkably effective china ash-tray in the shape of an Osram lamp, a specimen of which is now brightening our Editor's writing table. The illustration



Osram Ashtray.

here gives some idea of its appearance, but the gilt cap of the lamp should be seen to be appreciated. The Company offer to present the ash-tray free to contractors and other friends who may have seen this notice, and applications for these charming and useful souvenirs are invited.

A NEW PARALLELING VOLTMETER FOR ALTERNATING CURRENT

The central zero moving coil voltmeter has long been used for the paralleling of continuous-current generators in place of two separate voltmeters for the 'bus-bars and the incoming machine respectively, but in the case of alternating-current machines a corresponding instrument has not been available, although considerable attention has been devoted to the perfecting of the rotary synchroniser. The synchroniser has now practically superseded the synchronising lamps and voltmeters of bygone days, but does not by itself meet all requirements. The voltage of the incoming machine has still to be considered. The use of two distinct voltmeters or a voltmeter having two pointers working over a common scale is open to considerable objection. In the first place, the scale is usually somewhat cramped, so that it

The "Paller" for Alternating-current.
Paralleling Voltmeter.

has to be viewed from close by; and again, as two separate movements are involved, any error in one or the other of them will give an entirely erroneous impression as to the equality of pressure.

The construction of a central zero voltmeter to correspond with the moving coil continuous-current pattern presents some difficulties, but these have been surmounted in the instrument illustrated here, which has been introduced under the name of the "Paller" by Messrs. Everett, Edgcumbe, and Co., Ltd. (Collindale Works, Hendon). The apparatus is of extreme simplicity, being provided with four terminals, two for connection to the 'bus-bars and the other two to the incoming machine, and the windings are so arranged that equality of pressure is shown by the pointer standing at zero in the centre of the scale. Should the voltage of the incoming machine be higher than that of the 'bus-bars, the pointer deflects on one side of the scale, and if lower, to the

Hosted by Google

other. One side of the central zero is marked "too high" and the other "too low," to correspond with the voltage of the incoming machine. The voltmeter illustrated opposite is wound for a voltage of 100, and is suitable for connection to the secondaries of step-down pressure transformers, in which case the scale is often graduated to correspond with the primary or high-tension voltage. A feature of importance is the extreme openness of the scale on either side of the zero. In the case of a moving coil instrument for continuous current, this opening out of the scale is only possible by means of an auxiliary spring or some such comparatively complicated method, whereas in the present instrument it is a fundamental feature of the design.

In order to simplify matters still further for the switchboard attendant, an arrangement can be provided whereby an audible or visual signal is given when the voltage of the incoming machine is the same as that of the 'bus-bars, so that it is only necessary for the attendant to watch the synchroniser, the whole operation being rendered perfectly automatic.

These voltmeters can be fitted in a variety of cases, that shown in the figure having a 9-in. scale, which can be illuminated if desired. This forms a very convenient size, but many purposes a 12-in. scale may be preferred. In the case of continuous-current stations, it is often a great convenience to be able to move the voltmeter from one part of the board to another, and for this purpose a plugging-in voltmeter is often used. For alternating-current stations this is not as a rule required, owing to the fact that all the paralleling gear is usually collected at one spot, but if desired the present instruments can be fitted in cases provided with handles and a plugging attachment.

A 10,000-VOLT STORAGE BATTERY

AT a meeting of the Röntgen Society on Thursday last, Mr. A. A. Campbell Swinton made some interesting experiments with a 10,000-volt storage battery, which has been constructed in order that certain experiments with canal rays made by Mr. Swinton in 1907 might be repeated with continuous current, as was suggested at the time by Sir William Crookes. After referring to the 10,000-volt silver-chloride battery of Mr. W. de la Rue, constructed some thirty years ago, and the 40,000-volt battery of Prof. Trowbridge, Mr. Swinton described his own battery, which consists of 4,800 Planté cells, which are charged in sections of 80 cells each in parallel off the 200-volt supply. Connected in series, the battery gives 10,400 volts on open circuit. The cells are contained in five cabinets, each holding 960 cells arranged in twenty-four blocks of forty cells each. Each cell consists of a 4-in. glass test tube of $\frac{3}{4}$-in. bore, and each set of forty is cast solid with paraffin wax into a wooden tray. The plates are strips of sheet lead corrugated longitudinally, and are not pasted. Celluloid separators are employed. There are 400 lbs. of lead in the whole battery, which weighs nearly 1,000 lbs. complete. The battery is charged at the rate of 10 milliamperes only to avoid bubbling of the acid. Creeping has been prevented by this means, and the battery has a good insulation and keeps its charge well. It is capable of discharging at a rate of 150 milliamperes (*i.e.*, $1\frac{1}{2}$ kw.) for several minutes, and is highly dangerous to touch. The internal resistance varies with the current between 3,000 and 4,000 ohms, and the short-circuit current is estimated at two or three amperes. An adjustable water-resistance and a double-pole switch worked by cords are employed for safety. Mr. Swinton showed many interesting experiments, including the formation of striae in a 4-ft. vacuum tube, the rotation of mill-wheels by canal rays, and the Armstrong electro-capillary effect. The current could jump a 2·5 mm. spark gap, but even when there were no Leyden jars in parallel with the gap the discharge gave a whistling sound, showing that there were high-frequency oscillations due to the capacity of the wires, &c.

In the ensuing discussion Mr. W. W. Duddell referred to the 10,000-volt battery at the Reichsanstalt, Berlin, which delivered one ampere, for testing purposes, and stated that a 150,000-volt influence machine was being experimented with in London. He doubted whether it was possible to get an absolutely continuous discharge at such high pressures on account of the capacity and self-induction of the circuit.

Wireless Telegraph Notes.—It is stated that the Brazilian Government has commissioned the German Telefunken Co. to erect six wireless telegraph stations in Brazil. The same company have also received orders from the Argentine, Peru, Chili, and Uruguay Governments. all of whom have declared wireless telegraphy a State monopoly.

TESTS OF A 6,000-KW. TURBO-ALTERNATOR

A REPORT has just been issued by Messrs. Merz and McLellan, Consulting Engineers to the Newcastle-upon-Tyne Electric Supply Co., which contains results of tests of a 6,000-kw. turbo-alternator supplied last year by Messrs. Brown, Boveri & Co., Ltd., to the company's new power station at Dunston, and includes some remarkably low figures of steam consumption.

The set in question comprises a 9,000-b.h.p. turbine of the two-cylinder Parsons reaction pattern, with a uniflow h.p. cylinder, and the l.p. cylinder partly double flow, manufactured by Messrs. Richardsons, Westgarth & Co., of Hartlepool, to the designs of Messrs. Brown, Boveri & Co., of Baden (Switzerland), coupled to a 6,250-kw. Brown, Boveri alternator running at 1,200 r.p.m. The turbine was designed for a steam pressure of 190 lbs. per sq. in., and 190° F. superheat. The alternator is of the revolving-field type, rated at 7,000 k.v.a. at 0·9 power factor, 5,750 volts, three-phase, and is provided with a direct-coupled self-excited exciter. The surface condensing plant has 13,000 sq. ft. surface, and is of the "Contraflo" type, manufactured by Messrs. Richardsons, Westgarth & Co. The tubes are 18 B.W.G. and $\frac{3}{4}$ in. external diameter. The allowable circulating water per hour is 630,000 gallons at a specified inlet temperature of 50° F. The Edwards pattern three-throw motor-driven air pump has a capacity of 3·68 cu. ft. per barrel, and 1,660 cu. ft. per min. is the total volume swept through by the plungers. A vacuum augmenter is fitted with 400 sq. ft. surface, and the circulating pump is of Messrs. Greenwood & Batley's make.

Official tests of steam consumption were taken on December 16th last, with the following results:—

Output	4,256 kw.	5,600 kw.	6,257 kw.
Speed	1,210 r.p.m.	1,210 r.p.m.	1,210 r.p.m.
Steam pressure (lbs. per sq. in.)	192	192	192
Superheat	162° F.	166° F.	176° F.
Condenser pressure abs. (ins. of mercury)	0·81	0·88	0·90
Temperature in condenser	73° F.	75° F.	76° F.
Total water used per hour	52,902 lbs.	67,950 lbs.	75,000 lbs.
Water used per kw. hr. ...	12·44 ,,	12·14 ,,	11·97 ,,
Ditto. corrected for condenser leakage	12·42 ,,	12·12 ,,	11·95 ,,
Steam consumption corrected for 192° F. superheat and 29·1 ins. vacuum not allowing for power taken by auxiliaries ...	12·15 ,,	11·85 ,,	11·80 ,,

Parliamentary.—Although the Metropolitan Electric Supply Co.'s Bill which gives powers to acquire the Acton electricity undertaking is unopposed, it has been decided to refer it to a Committee to be treated as an opposed Bill. This is due to a suggestion by the Board of Trade, in consequence of the close division on the second reading of the Bill last week.

Automatic Signalling on the Metropolitan Railway.—The Metropolitan Railway has now adopted automatic signalling on their Baker Street—Neasden line, as well as on their portion of the Inner Circle. The system is described in the *Railway Gazette* and is all electric, having been specially designed for the service by the McKenzie, Holland & Westinghouse Power Signal Co., under the supervision of Mr. W. Willox, engineer to the Railway. The track circuit arrangements are similar to those on the District Railway, and can allow of 50 seconds headway between through trains. At St. John's Wood, Finchley Road, and West Hampstead, signal cabins have been retained for working crossings and sidings, but for normal working these boxes are closed and full automatic working is used. At Willesden Green a new cabin has been built with an illuminated track diagram. The 23 block sections over the five-mile stretch average 1,200 ft. in length, and automatic train stops are employed throughout. Lamp signals, dwarf signals, and semaphore signals are employed. In the two latter forms the line-clear position of the arm inclines upward instead of downward, so that it tends to fall naturally into the horizontal stop position and balance weights can be dispensed with. The gear, comprising electric motor, cut out, transmission gear, clutch and pneumatic buffer is fully enclosed and very compact. The arm is held in the clear position by an electromagnet, and thus drops to danger if the actuating current fails. Power is supplied by special motor generator sets in the sub-stations. All the signals are electrically lighted by two lamps in parallel, but oil lamps can readily be substituted. Automatic train describers have been installed at some of the stations, working on the same principle as those on the District Railway.

Hosted by Google

HIGH-TENSION TRANSMISSION LINES

THE two Papers on this subject by Mr. W. G. Taylor and Messrs. R. Borlase Matthews and C. T. Wilkinson, read before the Institution of Electrical Engineers on January 26th, were further discussed on February 23rd. Abstracts of the papers and reports of the previous discussions in London, Newcastle, and Manchester were given in ELECTRICAL ENGINEERING, February 2nd, February 9th, and February 23rd. The following is a report of the discussion in London on February 23rd :—

Mr. C. P. SPARKS (County of London Electric Supply Co., Ltd.) compared the 4,000 to 5,000 kw., which was commonly distributed per feeder in this country, with the 20,000 to 25,000-kw. circuits of the Paper. He did not agree that the pressure would be limited to 20,000 volts in this country; they might even reach 40,000 on account of the difficulties of handling the heavy conductors which would be necessary at the lower pressure. Transferring the load from a faulty line to another line, as done in some of the cases described, meant depriving important consumers of their supply for some time. It would be necessary, in this country, to adopt similar safeguards to those now used on underground systems to ensure continuity of supply. By working just below the critical pressure a heavy corona discharge would take place on the pressure rising due to lightning or other disturbances; this was a most practical safety valve. He thought that practicable H.-T. direct-current systems were as far distant as they were five years ago. It was necessary to provide more efficient earthing of the steel towers than was suggested in the Papers. The charges for power in America generated by so-called cheap water power did not compare favourably with the charges in England for power generated from coal.

Mr. W. B. WOODHOUSE (Yorkshire Electric Power Co.) referred to the difficulty of obtaining way-leaves in this country, consent sometimes only being granted for a few years, thus endangering the continuity of supply. Again, local authorities could, under the Electric Lighting Acts, refuse overhead lines being put up, even if they were run on private property and not across public highways. In America and most Continental countries legal machinery existed for providing way-leaves for public supplies, and he urged the Institution of Electrical Engineers to take up the question.

Mr. E. J. FOX (Stewarts & Lloyds, Ltd.) pointed out that the general consensus of opinion was that ten years was a fair average life for wooden poles, and thirty years for steel poles. The price of wooden poles was increasing daily, and at present they were almost as dear as steel poles. Mr. Trotter had put the life at about the same as steel poles, but the Board of Trade Regulations stipulated for a factor of safety of ten in the case of wood, and six in the case of steel. (Mr. Trotter intervened with the remark that he put the life of a wooden pole at about five times that of a steel pole.) The Papers referred entirely to towers built up of channels, angles, T's, &c. Much attention was now being paid on the Continent to tubular towers on account of their lower weight and first cost. The Cornwall Electric Power Co. were using tubular towers.

Mr. A. JACOB (British Aluminium Co., Ltd.) referred to the fact that the 110,000-volt system of the Hydro Electric Power Commission of Ontario employed between 300 and 400 miles of aluminium wire. The average span was 520 ft., with 65½-ft. towers. Altogether some 2,000 tons of aluminium had been installed, including the distribution system at 13,500 volts. The factor of safety required in this country was twice that demanded in Canada, notwithstanding that the weather conditions there were much more severe. The formula used for calculating the stress due to wind pressure for both copper and aluminium cables did not take into account the elasticity of the metals, and consequently the stresses calculated were much greater than those met with in practice. The error might be as great as 400 per cent., and the result was an unnecessarily heavy and costly pole line construction. The Macintyre joint had solved the difficulty of jointing aluminium cables, and had even been adopted on copper lines. The troubles due to galvanic action had now been overcome by the use of aluminium for binders and clamps, or by providing ample protection from moisture when other metals were used. Alloys of copper with aluminium, although giving a higher tensile strength, had a higher resistance than pure aluminium, and also corroded very readily. Experience showed that aluminium lines did not corrode more readily than copper lines, even on the sea coast. In a certain case described by Mr. Taylor a saving of 35 per cent. would have been accomplished by the use of aluminium cables, allowing for the necessary differences in pole line construction. Mr. Jacob then exhibited a number of slides of aluminium lines erected by the British Insulated & Helsby Cables, Ltd., in this country, including some cases of lines in South Wales where solid aluminium conductors have been used for street lighting and distribution to small houses.

Mr. C. GREEN referred to some tests which showed that the Macintyre joint had only 60 per cent. of the strength of the wire. A bolted-up clamp joint had been used on aluminium lines by the British Insulated & Helsby Cables, Ltd., and it would be interesting to know the strength of this joint as compared with the wire. Aluminium conductors would, he thought, be more likely to swing out of phase with sudden gusts of wind on account of their lightness. He believed that the cost of wooden poles was less than that of steel poles with spans up to 100 yards.

Mr. E. H. RAYNER (National Physical Laboratory), after commenting upon the large amount of plant which had to be kept running in order to keep the line charged, even on conditions of light load, pointed out that with star-connected E.H.T. transformers it would only be necessary to insulate one terminal of each transformer. A strong argument for high pressures was the fact that by doubling the pressure it was possible to double the capacity of a line without increasing the capital cost of the line more than a few per cent. Lightning was also less dangerous at 100,000 volts than at 20,000 volts, and working just below the critical corona pressure was an excellent safeguard. He knew insulators which had failed owing to the glaze not extending over their whole surface.

Mr. H. BRAZIL (Charing Cross, West End & City Electricity Supply Co., Ltd.) thought that lightning arresters could be arranged with resistance in series, so that they could do their duty without disturbing the line. Aluminium cell arresters were not, he thought, reliable. Water jets for discharging the line of any accumulated charge were unsatisfactory for various reasons; a carbon power resistance was very reliable for this purpose. Finally, he thought that generally too many lightning arresters were installed, and that one or two in good condition on the main 'bus-bars would be more efficient.

Mr. B. M. JENKIN (Messrs. Kennedy & Jenkin) referred to the increased difficulties which would arise when duplicating E.H.T. lines, on account of the extra way-leaves required.

Mr. A. J. STUBBS (Assistant Engineer, G.P.O.) referred to the unsatisfactory experience of the Post Office about ten years ago with aluminium wires, and described a number of tests which showed that under continued stress aluminium wires had a much greater permanent elongation. British-made Post Office insulators did not, he said, depend upon the glazing for their insulating properties.

Mr. F. V. T. LEE, who has been responsible for some installations in California, called attention to the use of synchronous motors to maintain the power factor. On one 67,000-kw. system, with eleven power-houses, regulation was effected by means of tappings on the transformers at the sub-stations. Difficulties sometimes arose with regard to way-leaves in America and Canada, as in this country, when they came to municipal areas. He was of the opinion that 100,000 volts would remain the limit for some time. With regard to protection against lightning, he thought that the gap arrester with a small resistance in series was best. To ensure continuity of service it was essential to have duplicate pole lines with different routes if possible. He emphasised the importance of fireproof insulation for transformers, and advocated the use of three single-phase transformers instead of a single three-phase transformer with large capacities. Experience had led him to prefer for 600,000 volts a horizontal break switch with plenty of oil. Mr. Taylor's figures of depreciation seem to be rather low. In California they were not able to cut poles down as the line was being erected; all their poles had to come from Oregon, over 1,000 miles distant. A life of ten years was a fair average, although some had lasted forty years. The poles were not treated. There was a good future for concrete poles, as cement was becoming cheaper, and wood and steel dearer. The only basis for assuming a life of thirty years for steel towers was the fact that windmill towers of this character had lasted for that period. The general practice in California was to have ten towers to the mile, or twenty poles. Until recently forty poles to the mile was the usual construction, but owing to the cost of insulators due to troubles with them, it was found that a cheaper and better line was obtained by cutting out every other pole. There still remained the need for a properly designed horizontal strain insulator. In conclusion, the speaker advocated the installation of additional stand-by plant at the receiving end of the line rather than the duplication of the pole line. In his experience, a 3,000 kw. gas engine plant had been put into service within 35 seconds from the time of interruption of the overhead line.

Mr. R. BORLASE MATTHEWS replied briefly to the discussion. He said that two projects were now under consideration involving transmission over distances up to about 400 miles with a pressure of 165,000 volts. Experience showed that the greatest difficulties were encountered between 30,000 and 80,000 volts, and that above and below these points the troubles were very much less. With regard to the use of a ground wire, opinion in the United States and other parts of the world was practically unanimous in favour of a steel ground wire over the conductors. The practice in the Newcastle district of carrying the ground wire underneath the conductors had not been seriously considered elsewhere.

CIRCUIT BREAKING

A PAPER entitled "Breaking high and low potential circuits," by Mr. A. G. Collis, was read on Thursday, February 23rd, before the South Wales Institute of Engineers, at Cardiff. The author pointed out the growing importance of extremely rapid opening of circuit breakers on short circuits, especially in view of the quality of turbo-generators standing up to their work under fault conditions. He referred briefly to previous investigations of Prof. B. Hopkinson and Mr. Miles Walker, and spoke of a switch

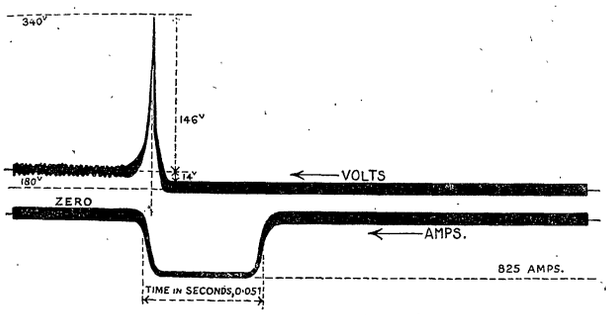

FIG. 1.—BREAKING ON PREDETERMINED LOAD. CIRCUIT BREAKER WITH STRONG MAGNETIC BLOW-OUT. 825 AMPERES. 180 VOLTS D.C.

that had recently been designed to open in 1/500 sec. on a short circuit in which the energy of the circuit was dissipated in resistances composed of thin metal strips immersed in oil and gradually thrown into the circuit by the motion of the switch blade. The objections to the use of oil switches for continuous currents on account of abnormal pressure rise and carbonisation of the oil were, he thought, overrated, and he quoted Mr. W. Browning's statement that a contact immersed in oil has at least twice the conductivity of a

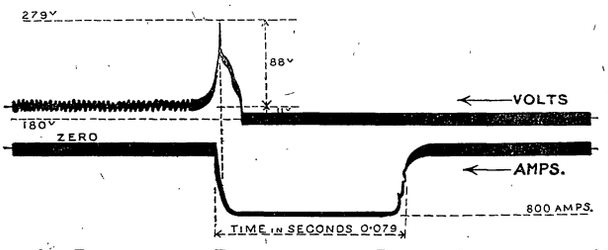

FIG. 2.—BREAKING ON PREDETERMINED LOAD. OIL-SWITCH. 800 AMPERES. 180 VOLTS D.C.

similar dry contact. He commented on the futility of attempting to construct really gas-tight switchgear, and suggested gauze or plate protection.

The principal part of the Paper was devoted to a description of a series of oscillograph records of the action of seven or eight typical forms of circuit breakers, including carbon air breaks, with and without magnetic blow-out, and breaks under oil and water. An ordinary fuse was also tested. In the first series of tests a predetermined continuous current

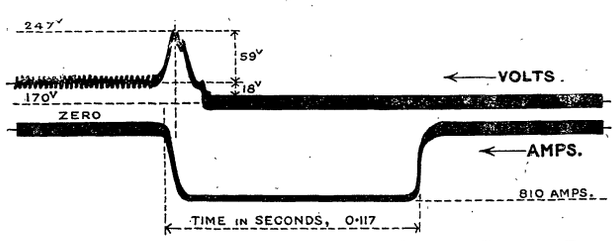

FIG. 3.—BREAKING ON PREDETERMINED LOAD. CARBON BREAK ON INDUCTIVE CIRCUIT. 810 AMPERES. 170 VOLTS D.C.

load was suddenly thrown on to the circuit-breaker by opening a diverting switch, and the oscillograph was arranged to record the current through the circuit-breaker and the voltage across its terminals. A typical oscillogram is shown in Fig. 1 (with the voltage scale inverted for clearness), which is for a breaker with a strong magnetic blow-out, actuated by a series coil. The next breaker tested was provided with a continuously maintained blow-out field. The time occupied both before the commencement of and during the break is about the same, but the rise of pressure seems higher for corresponding currents. In both cases the rise of pressure is a function of the current interrupted. A typical record for continuous current break under oil is given in Fig. 2. Both the times taken in completely interrupting the circuit and in disrupting the arc are considerably longer than with the air breaks with magnetic blow-out, the latter probably

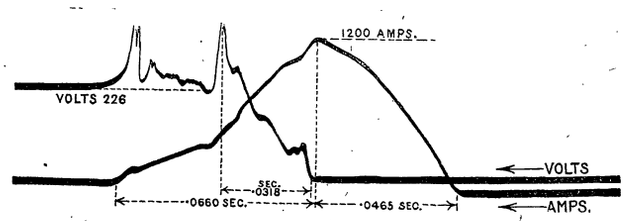

FIG. 4.—SHORT-CIRCUIT CONDITIONS. OIL-BREAK SWITCH ON D.C. GENERATOR.

due to the feeding of the arc by the vapour of the oil. The pressure rise is remarkably less, as might be expected. Further tests with a non-magnetic blow-out carbon air-break show a relatively low pressure rise and longer time of disruption of the arc (see Fig. 3). Other tests were also made with a view to show the effect of varying the number of turns in the blow-out coil. It was remarked that the short break with strong magnetic field appears to be giving way to a wider break with comparatively weak field. An ordinary

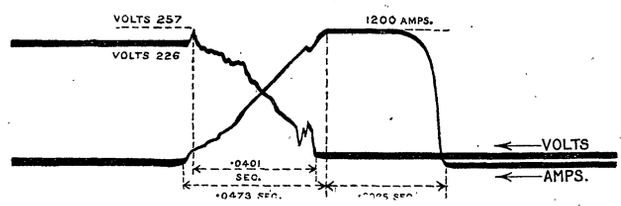

FIG. 5.—SHORT-CIRCUIT CONDITIONS. OIL-BREAK SWITCH ON BATTERY.

fuse was also tested, which took about 2½ times as long as a blow-out circuit breaker to interrupt the same current. Replacing the oil in the oil switch tested by water had the effect of reducing the rise of pressure. It must be understood that in all the above experiments the load was inductive, consisting of a motor driving a pump.

The next series of experiments represented dead short circuit conditions, and Figs. 4 and 5 give the results with oil-break circuit-breakers on a steam-driven generator, and a battery respectively. The voltage curves are not here inverted. It will be seen that the dead short on the generator was interrupted in about 1/10 second with a pressure rise of only 200 volts, the current reaching a value of 1,200

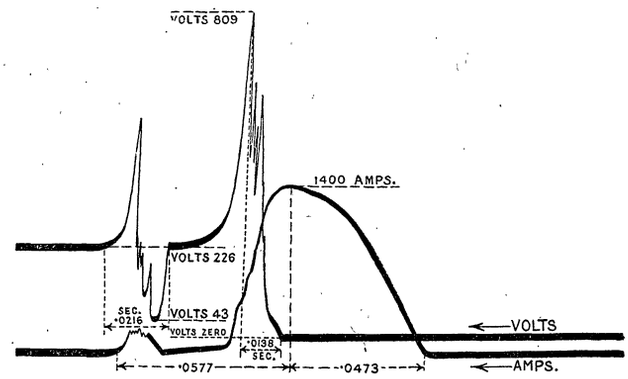

FIG. 6.—SHORT-CIRCUIT CONDITIONS (D.C. GENERATOR). MEDIUM FIELD MAGNETIC BLOW-OUT BREAKER.

amperes. The variations in the current due to the changes in the resistance of the arc are reflected in the voltage curve, and there is only a very small upward kick of pressure at the final rupture of the arc. In Fig. 5 the absence of inductance is shown in two ways; the steep rise of the current curve when the circuit is closed and the small rise of pressure at final break. The limit of supply of the battery was

Hosted by Google

about 1,200 amperes, and was reached before the breaker opened. The most remarkable of the records with magnetic blow-out breaker is reproduced in Fig. 6. Here a violent fluctuation of the arc is responsible for a rise of pressure of 583 volts; the arc appears to have been disrupted, and then to have started again, the final kick amounting to 316 volts. This record refers to the generator, and not the battery. The same circuit-breaker cleared a battery short circuit in 0·0156 sec., which is the quickest action in any of the tests. The author considers that these tests point to the facts that continuous current oil-breaks are satisfactory, and that a carbon break tends to reduce the rise of pressure at rupture of the circuit.

Finally, alternating currents were experimented with. A typical curve is shown in Fig. 7. Here, the current wave was interrupted as it was approaching zero value. There was an immediate inductive pressure rise, which appears to have been checked very suddenly, probably on account of the fact that the impressed voltage wave is endeavouring

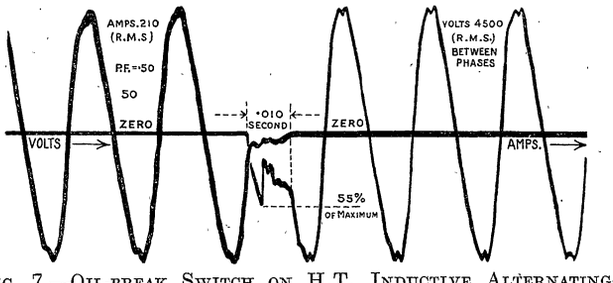

FIG. 7.—OIL-BREAK SWITCH ON H.T. INDUCTIVE ALTERNATING-CURRENT CIRCUIT.

to establish itself in an exactly opposite direction to the direction of the induced volts. On the other hand, it would appear that it only required a period of time represented by one-half of the complete period 0·010 sec. for the voltage wave to establish itself in a normal manner, and it will be noted that the first complete half-wave of the voltage curve reached its normal maximum value.

In all cases the records show that the circuit may open at any point on the current curve; but after the current has died down to zero value it never again rises on the other side of the zero line. It would appear, in fact, that in all cases the oil rushes in between the contacts, and prevents an arc being drawn out, which otherwise might permit the current to rise again after it has passed through zero value. Similar results were obtained with low-tension tests.

DISCUSSION.

After a few remarks by the Chairman, Prof. A. C. Elliott, the discussion was opened by Mr. E. B. WEDMORE (British Thomson-Houston Co.). He did not see much point in moderate field circuit breakers, and preferred the ordinary carbon breaker. With large power short circuits, breakers must open very rapidly to check the current rises. If the time required is doubled, the heating effect on the switch is increased eight times. The carbons even of quick breaking switches often get red hot, and there is difficulty in preventing them cracking and flying. The magnetic blow-out was useful where the breaker had to be enclosed, and gave a quick break on small powers without undue heating. Oil was useful for enclosing the sparking point of breakers, but stopped the dispersal of the metal vapour, and thus caused increased burning and wear. With continuous current there was danger of firing the oil. He preferred non-automatic switches for general mining work, with the automatic features in a safe portion of the mine. Mr. Wedmore also spoke of the advantages of the free-handle type of circuit breaker, and remarked that the alternating current tests were limited by the small amount of power available. On testing breakers of the size used with their full currents, the current had been found to pass repeatedly through the zero value before the arc was quenched. With reference to Mr. W. Browning's tests, vaseline on the breaker contacts reduced contact resistance, and at small distances oil was easier to puncture than air.

Mr. J. E. TEASDEL said that a 2,000 ampere circuit breaker would open quicker than a 25 ampere fuse in series with it. He recommended breakers in preference to fuses for all motors over 5 h.p., and wished to know whether zinc tips for circuit breakers had been tried.

Mr. W. A. CHAMEN also regretted the limited power available on the tests, and suggested that troubles might be introduced by the rushes of current at certain points in the wave due to the brands of transformer iron now used.

Mr. COLLIS, in his reply, referred to an 800 ampere 400 volt switch in successful use in a planing machine circuit, which was opened and closed several times a minute. He also spoke of the impossibility of making even oil switches really gas-tight, and with reference to Mr. Teasdel's remarks mentioned some tests on a large battery at Manchester, where the fuses had always opened before the circuit breakers.

A written communication from Mr. A. M. TAYLOR was then read, in which reference was made to a circuit breaker of his design, which contained both a magnetic blow-out and oil quenching, and was expected to be able to open an alternator circuit in 0·002 second. This switch had been designed to give the energy of the circuit first to the oil, then to the water, and hardly any to the arc.

Mr. COWAN, in another communication, wrote that in his experience oil switches had worked satisfactorily on continuous current motor circuits. There was more carbonisation than with alternating currents, but if the design was such that the carbon particles did not lodge on insulating surfaces, but fell to the bottom of the tank, that did not interfere.

Mr. J. G. STATTER wrote advocating oil immersed contacts for low as well as high pressures, and pointed out the advantages of the sucker over the dash-pot pattern of time lag.

Mr. W. B. WOODHOUSE had worked with oil switches for continuous currents, but found that the carbonisation rendered frequent changing of the oil necessary. They had been employed on coal cutters, changing the oil entirely every month.

A long communication from Mr. J. S. PECK was also read, who thought that the subject was too wide for general conclusions to be drawn from these tests. He pointed out that the volt coil of the oscillograph in the tests in the Paper was connected across the breaker, and thus did not take account of the impedance being divided between the generator and the motor. He thought that it was wrong to state that in alternating current breaking the current never passed its zero value, and quoted published oscillograms supporting his view. After a few remarks from Mr. Collis in reply, the discussion was adjourned.

SYMBOLS

AT the unofficial Conference of the International Electrotechnical Commission, held at Brussels in August, 1910, the delegates expressed the desire that the following propositions in reference to symbols should be studied by the various Electrotechnical Committees, with a view to formal adoption at the next plenary meeting of the Commission, to be held at Turin in September, 1911. Anyone interested in the subject should send in his observations to Mr. P. F. Rowell, Secretary of the British Electrotechnical Committee, Institution of Electrical Engineers, Victoria Embankment, W.C.

That small letters be reserved for the representation of the instantaneous values of electrical quantities which vary with the time. That capital letters be reserved for the representation of effective or constant values of electrical quantities. That capital letters followed by the subscript "m" be reserved for the representation of the maximum values of periodic electrical quantities. That capital script letters be reserved for the representation of magnetic quantities, constant or variable. That capital script letters accompanied by the subscript "m" be reserved for the representation of the maximum values of magnetic quantities. That the following letters be reserved for the representation of the following quantities: Electromotive force, E, e; Electric quantity, Q, q; Inductance, $\mathscr{L}$; Magnetic force, $\mathscr{H}$; Magnetic flux density, $\mathscr{B}$; Length, L, l; Mass, M, m; Time, T, t.

National Electrical Manufacturers' Association.—The first meeting of the new Council of this Association, which was elected last Tuesday under the new Articles of Association, will be held at Balfour House, Finsbury Pavement, E.C., on Tuesday next at 2.30 p.m.

South-Western Polytechnic.—The annual distribution of prizes and certificates will take place at the Institute, Manresa Road, Chelsea, on Friday, March 10th. Sir Alfred Keogh, K.C.B., will present the awards, and the chair will be taken by Mr. W. Hayes Fisher, M.P. The laboratories and workshops will be open to inspection.

Royal Institution.—Among the lecture arrangements after Easter are included a course of two lectures by Mr. T. Thorne Baker on "Changes Effected by Light" and "Practical Progress in Wireless Telegraphy" respectively. Among those who will probably deliver Friday evening discourses are Mr. G. Marconi and Prof. Svante Arrhenius.

American Electric Lamp Combine.—Information from America states that the Cleveland (Ohio) authorities have taken action against the General Electric Co. of Schenectady in connection with the agreement with the National Electric Lamp Co., which it is alleged is an unlawful combination and conspiracy in restraint of trade. It is declared that agreements exist with the Westinghouse Co. and others to sell lamps at fixed prices, and that special companies have been organised to sell inferior lamps in order to damage the trade of genuine independent companies. It is thought possible that the dissolution of the combination will be effected without long litigation.

PHASE DISPLACEMENTS IN SYNCHRONOUS MACHINES

MR. W. W. FIRTH read a Paper on February 20th before the Newcastle local section of the Institution of Electrical Engineers entitled "Measurement of Relative Angular Displacements in Synchronous Machines." He pointed out that when the working conditions of a generator and synchronous motor system are changed by alteration of load or excitation of either machine, a relative mechanical displacement of the rotors takes place, and if the change is sufficiently rapid there is an oscillation or phase swing about the new position of equilibrium which is quickly damped out by eddy currents and friction. The magnitude of the steady displacement is governed by the condition that the vector sum of the circuit voltages must be zero, or, in other words, that the resultant of the generated voltages of generator and motor is equal to the impedance-drop in the circuit. These voltages depend upon the exciting currents of the machines together with their armature reactions, whilst the impedance-drop is proportional to the line current.

He proceeded to consider the matter mathematically, and developed a vector diagram illustrating the effect, which showed that this change of phase position is partly due to the change of impedance-drop, but chiefly to the change of the generated voltages by armature reaction. Even when the power factor in the generator is unity, armature reaction has a weakening effect on the main field; in fact, the angle of lead must be considerable before the action becomes strengthening. In the motor the armature field only strengthens the main field when the lag is fairly large. Stated generally, a lagging current in the line always has a demagnetising action in the generator, and a leading current a demagnetising one in the motor; further, to produce a magnetising action in the generator or motor, the line lead or lag respectively must exceed a certain value, which depends upon the magnitude of the line current.

The truth of these conclusions was confirmed experimentally on machines fitted with exploring coils to observe the change of flux, and a simple optical arrangement arranged so that the angular displacement of a mirror carried on one machine deflected a beam of light allowed to fall on it once per revolution through a slot carried by the other machine. Curves of observed displacements for various circumstances are given in the paper, from which it is seen that the displacement decreases with increase of speed for any given load; that it is much less in three- than single-phase machines and less again for converters than for synchronous motors. Photographic records of the movement of the spot of light show the phase displacements and swing due to various circumstances. These diagrams also show the natural period of the swing, and the marked difference in its value thus revealed from that obtained from the formula of S. P. Thompson is interpreted as indicating that the voltage drop in alternators is almost entirely due to demagnetising armature reaction, the true or leakage inductance drop being practically negligible.

DISCUSSION.

Dr. W. M. THORNTON (Armstrong College, Newcastle) defined "phase swing" as a mechanical swing controlled by the elastic nature of the magnetic lines of force, voltage and current remaining strictly in phase in both machines, the latter varying during the swing in time with the movement. The two problems to be investigated were: shift of load and shift of field strength.

Mr. LEAKE suggested plotting phase displacement against total load. The Paper clearly showed that the actual magnetic centre line shifted, contrary to what had hitherto been commonly assumed, and the maximum voltage in a generator was thus reached somewhat later than was usually thought to be the case. He suggested that the demagnetising ampere turns in an alternator were not equal to $\sin\phi$ but to $\sin(\phi+\alpha)$ where α is the angle through which the magnetic centre line moves. The ratio of actual back ampere turns to calculated back ampere turns was thus equal to $\frac{\sin\phi+\alpha.}{\sin\phi}$ He questioned the correctness of measuring the voltage with ϕ nearly equal to 90° when predetermining alternator characteristics by the Fischer Hinnen and Potter methods, as the values thus arrived at are probably in error due to phase displacement.

Mr. W. T. MACCALL (Sunderland Technical College) made some suggestions as to how the results might have been presented with greater clearness. He had worked out some cases roughly showing break of step with less relative displacement when under light loads. The weakening of the field in the case of the light load accounted for this apparent anomaly. He pointed out that, contrary to the general assumption, an armature current of unity p.f. did actually weaken the main field, and Mr. Firth had experimentally verified that this was so.

Messrs. C. FARADAY PROCTOR and P. V. HUNTER also spoke, and Mr. FIRTH briefly replied to the various speakers.

RECENT ELECTRICAL DEVELOPMENTS AT DRURY LANE

ABOUT a week ago a new and pleasing electrical effect was introduced into the Drury Lane pantomime, "Jack and the Beanstalk." After the Widdicombe Market scene two large pieces of iron framework are pushed on from opposite sides of the stage. These consist of a number of small iron ladders held in position by a frame and leaning slightly back at the top. They are painted green, and are carried on low-wheeled carriages. On the carriages, hidden from view of the audience, are eighteen Chloride accumulators, each having a capacity of 200 amp. hours, in lead-lined teak boxes. Running from these cells are thirty-six separate 4-volt circuits, all provided with double-pole fuses in porcelain chambers and double-pole switches. Each of these circuits terminates in a plug socket on the front of the framework.

The two halves of the frame meet together in the middle of the stage, thus forming one large frame measuring 36 feet long by 18 feet high. Directly it is in position the troop of Boy Scouts proceed to storm it, each carrying a rectangular piece of cloth, long enough completely to hide him, one side being coloured khaki and the other red, white, or blue. On the latter side are also 4-volt lamps, agreeing in colour with the cloth. At a blast from a bugle every boy reverses his cloth, producing an enormous Union Jack. They then insert plugs into the sockets provided, and at another blast of the bugle the flag is outlined with some 3,300 electric lamps of the proper colours.

A very effective scene is that of the storm, in which the wind is so strong that people are blown clean off the stage—when assisted by wires from the flies. This mighty hurricane is produced by a couple of 25-h.p. motors and blowers, supplied by the Electric Ordnance and Accessories Co.

The "big" scene this year is the harp scene. Nine enormous harps are lowered so as to hang several feet from the stage, and each is provided with 160 coloured lamps, each of 2½ c.p. and taking 50 volts, arranged that there are only two lamps per circuit, and all the circuits are fed through rotatory switches in the flies. When the real harps begin to play, the switches are worked, and the result is that the lamps on the harp strings are alternately extinguished and illuminated in such a way as make it appear that light is travelling down the strings.

Some 9,000 metal-filament "Z" lamps are used in the theatre, in addition to the "effect" lamps previously mentioned; 32-c.p. are employed on the stage, 25-c.p. for corridors and ceilings, and 16-c.p. for ordinary rooms. All are run at 100 volts.

With regard to the outside of the house, it may be remarked that a new switchboard has recently been installed in the intake room at the front. This board controls twelve new "Excello" white-flame arc lamps, and is of the three-wire type. On it are twelve ways for controlling the arcs, which are run two in series. The remaining six ways are provided for the special Coronation illuminations which it is proposed to put up. Messrs. Baxter & Caunter were responsible for the construction of the board.

In concluding these notes, we have to acknowledge the courtesy of the theatre management in enabling our representative to obtain information, and especially are we indebted to the stage manager, Mr. Ernest D'Auban, and to the electrician, Mr. Mather.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

ILLUMINATION DEVICES, &c.—An advance sheet from the Sun Electrical Co., Ltd., 118-120 Charing Cross Road, W.C., illustrates a fine example of coronation decorative illumination, making use of a special miniature strip with watertight porcelain holders with small bulb 10 to 14 volt 2-c.p. lamps run in series at 2½ or 5-inch centres.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

KALKOS FITTINGS.—Some further leaflets from the Sun Electrical Co. deal with the switch to which we referred on January 12th in connection with remarkable results of durability tests. Reduced prices are quoted for certain Kalkos fittings.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published March 2nd, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

3,098/10. **Solenoid-controlled Switchgear.** J. G. CHILDS and T. S. HILL (London). In A.C. solenoid operated gear, the cores of the solenoids or electromagnets are provided with counterbalance weights in order that the magnetic pull may be almost wholly available for exerting pressure at the contacts. Further, the contact surfaces are placed at an angle to the solenoid axis in order to increase the pressure for a given pull. Four figures.

3,336/10. **Carbon Brushes and Electrodes.** BRITISH THOMSON-HOUSTON CO., LTD. (*General Electric Co., U.S.A.*). Brushes or electrodes of increased density and mechanical strength and of high conductivity are produced by moulding from a mixture of carbon and a carbonaceous binder and baked to a temperature of 480° C. They are then impregnated with pitch or other suitable material, and fired to a temperature of about 1,400° C. The following result is given as an example: apparent density, 1·66; absolute density, 2·05; porosity, 19 per cent.; resistance, 0·00108 ohm per inch cube; tensile strength, 2,130 lb. per sq. in. Two figures.

4,885/10. **Arc Lamp.** JOHNSON & PHILLIPS, LTD., and J. BROCKIE. This specification describes the mechanism of a magazine flame arc lamp of the pattern in which the magazines have each two compartments from which the carbons are fed alternately. When the burning carbons cease to be fed forwards, another pair of carbons is brought forward by the feeding mechanism into such a position that the arc transfers itself to this pair without any lateral movement of the magazines or extinction of the arc. Four figures.

6,535/10. **Printing Press Controller.** T. BARNARD and C. EDWARDS (Toronto). Various detail improvements in solenoid-operated controllers with the object of rendering them safe and reliable, and of rendering possible very fine variations in speed, are described. Eight figures.

11,184/10. **Motor Starters.** ADAMS MANUFACTURING CO., LTD. (*Cutler Hammer Manufacturing Co., Ltd., U.S.A.*). In starters in which the spindle extends through the core of a blow-out magnet, one set of pole-pieces of the magnet are arranged on the rear side of an insulating slab opposite the contacts on the front side. The other set of pole-pieces is formed by radial contact arms mounted on the spindle. Nine figures.

27,710/10. **Supports for Metal Filaments.** LICHTWERKE GES. (Berlin). Elastic supports for preventing the sagging of metal filaments are made of an alloy of molybdenum with a small percentage of a highly refractory and brittle metal, such as tungsten, chromium, titanium, or vanadium. A wire containing 2 per cent. of tungsten is said to give excellent results. It is stated to be as elastic as watch-spring steel, and not to lose its elasticity with continued heating and cooling.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: RAILING and ANGOLD, 5,416/10; BISSON and BERGÈS, 12,149/10.

Dynamos, Motors, and Transformers: SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke Ges.*) [Speed regulation of polyphase motors] 5,119/10; BRUSH ELECTRICAL ENGINEERING CO. and JONES [Cooling of commutators and slip-rings] 12,889/10.

Electric Ignition: GRAVDAHL [Reversing engines with electric ignition] 19,625/10; R. BOSCH [Connecting cables of ignition apparatus] 24,688/10.

Electrometallurgy and Electrochemistry: SIEMENS BROS. & CO. (*Siemens & Halske A.-G.*) [Purifying water by ozonised air] 17,787/10.

Heating and Cooking: BRITISH THOMSON-HOUSTON CO., LTD. (*General Electric Co., U.S.A.*) [Electric heaters] 26,120/10.

Instruments and Meters: SIEMENS & HALSKE A.-G. [Frequency meters and recorders] 16,342/10.

Storage Batteries: SMITH [Connector for use when charging accumulators] 7,593/10.

Switchgear, Fuses, and Fittings: MILCH [A.-C. induction current regulator] 869/10; JOEL [Portable battery lamp] 3,185/10; GIBBS and SANDYCROFT FOUNDRY CO. [Controllers] 4,190/10; CUNNINGTON [Twin lamp-holder] 4,299/10; DEAN [Iron-clad switch fuses] 5,054/10; CHARLTON [Switches] 6,704/10; SIDLER [Switches] 21,174/10; FORSBERG [Electromagnets] 22,394/10; KALAMBA [Plug connectors] 27,375/10.

Telephony and Telegraphy: WALL [Telephone calling apparatus] 3,582/10; EVERSHED & VIGNOLES, LTD., KILROY and MITCHELL [Signal devices] 4,427/10; MARCONI'S WIRELESS TELEGRAPH CO. and FRANKLIN [Receiving stations] 4,910/10; MARCONI'S WIRELESS TELEGRAPH CO., BANGAY and PRINCE [Portable wireless apparatus] 11,359/10, and [Portable motors and dynamos] 11,360/10; VON KRAMER [Inductive wireless telephony] 16,419/10; NEMETH [Telephonic distribution of music, &c.] 21,700/10; FORSBERG [Telephone call indicators] 22,394/10.

Traction: LUARD and THOMPSON [Flexible tubular connections for railway coaches] 3,941/10; CUNLIFFE and DEWHURST [Electric signalling] 4,230/10; MCKENZIE & HOLLAND, LTD., HUDD and HAYWOOD [Electric signalling] 4,997/10; FIXLER and BURGESS [Trolley stands] 12,862/10; SYKES, COOKE and JOHNSON [Insulated rail-joints] 16,933/10; JOHNSON [Rail-joints] 23,413/10; CONSOLIDATED BRAKE & ENGINEERING CO. and HARDING [Automatic brakes] 23,436/10.

Miscellaneous: BUTIKOFER (*Maitre*) [Soldering aluminium] 3,439/10; NEVATTE [Burglar alarm] 4,035/10; HAILWOOD [Miners' safety lamps] 6,928/10; LAUREYS [X-ray tubes] 14,004/10; KOVATCH [Coal-cutters] 18,135/10; FISCHER [Electrically-actuated typewriter] 20,526/10; KEITH [Centrifugal fans] 23,096/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: A.-G BROWN, BOVERI ET CIE [Frequency transformers] 600/11.

Electric Ignition: HARLÉ ET CIE. [Submarine mines] 2,713/11.

Electrochemistry, &c.: FRIEDMANN [Electroplating] 12,931/10; HESSELN [Two-fluid primary cells] 26,959/10; A.-G. FÜR OZONVERWERTUNG SYSTEM ELWORTHY-KÖLLE [Ozone apparatus] 3,119/11; OTTO [Sterilising water by ozone] 3,250/11.

Instruments, &c.: ALLGEMEINE ELEKTRICITÄTS-GES. [Meter for recording consumption above a certain amount] 1,930/11.

Switchgear: R. BOSCH [Contact pins] 72/11.

Telegraphy, &c.: SIEMENS & HALSKE A.-G. [Signalling] 2,014/11; BELLINI and TOSI [Wireless aerials] 2,632/11; MCBERTY [Automatic telephone selectors] 3,452/11.

Traction: ALBANESE [Conduit and track for slot traction system] 3,022/11.

Opposition to Grant of Patents

17,960/09. **Metal Filament Lamps.** FELTEN & GUILLEAUME LAHMEYER-WERKE A.-G. As a result of opposition, the right to a grant on this application has been surrendered. The specification (abstracted in ELECTRICAL ENGINEERING, May 26th, 1910, p. 346) describes the prevention of disintegration of the filaments by the introduction of phosphorus-nitride into the bulb.

22,997/09. **Heating Apparatus.** H. A. KENT. This patent has been granted in spite of opposition, but the Comptroller's decision requires an amendment of the specification. The patent covers heating elements consisting of tungsten granules enclosed in silica glass tubes, and was abstracted in ELECTRICAL ENGINEERING, October 6th, 1910, p. 636.

27,458/09. **Automatic Telephone Exchanges.** SIEMENS BROS. & CO., LTD. (*Siemens & Halske A.-G.*) The opposition to the grant of this patent has been withdrawn. An abstract of the specification was published in ELECTRICAL ENGINEERING, October 27th, 1910, p. 688.

Application for Revocation Dismissed

18,628/08. **Electric Ignition.** A. M. LOW. The application for the revocation of this patent, noticed in ELECTRICAL ENGINEERING of September 22nd, 1910, p. 608, has been dismissed. The patent covers a sparking plug in which one electrode is cup-shaped, and the other a point at the axial centre of the cup.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Distribution Systems, &c.: CALLENDER'S CABLE & CONSTRUCTION CO. and A. V. DOWNTON [Cable stranding machinery] 23,757/05.

Dynamos, &c.: R. ROUGÉ and G. FAGET [Rotary converter] 5,562/00; G. G. MILNE [Train-lighting dynamo] 25,053/03; H. H. LAKE (*C. A. Gould, U.S.A.*) [Train-lighting system] 25,112/04.

Electric Ignition: EVERSHED & VIGNOLES and S. EVERSHED [Magneto blasting dynamo and indicator] 20,466/00.

Instruments, &c.: G. K. B. ELPHINSTONE and A. C. HEAP [A.C. moving-coil ammeters and voltmeters] 26,399/97.

Switchgear, &c.: O. O. POLLOCK [Prismatic lamp-shades and reflectors] 23,811/05.

Traction: P. WHEELER [Operating car doors] 24,535/04.

Miscellaneous: T. J. HOWELL [Induction coils] 24,701/03; W. CHADBURN [Solenoid-operated ships' telegraph] 23,607/05; T. A. B. CARVER [Electrically operated "let-off" motion for looms] 23,746/05.

Hosted by Google

THE WELSBACH COMPANIES

TO the electrical industry the scheme of reorganisation of the Welsbach Incandescent Gas Light Co., Ltd., sanctioned at an extraordinary general meeting of the company last Thursday, is of considerable interest in view of the existence of an Electric Lighting Department inaugurated by this company about eighteen months ago. The German Welsbach Co. (the Deutsche Gasglühlicht Aktiengesellschaft), who will hold the controlling interest in the new company, is, as is well known, considerably interested in the Osram Lamp Works of Hammersmith in conjunction with the General Electric Co., Ltd., of London, and some of the fundamental patents under which the Osram lamp is made were acquired by the Osram Lamp Works from the German company.

The police court proceedings by the latter to prevent the English Welsbach Co. using the word "Aur" on their metal filament lamps will still be fresh in our readers' memories. It was currently reported at the time that the German Welsbach Co. were by no means pleased with the action of the English company in selling metal filament lamps, and it will now be interesting to see what steps will be taken with regard to the large electric lamp business which the Welsbach Co. have built up, for it does not seem probable that the German company will countenance the sale of lamps of another make in competition with the Osram unless under licence to the owners of the Osram patents.

The provisional agreement between the Welsbach Incandescent Gas Light Co. and the Deutsche Gasglühlicht Aktiengesellschaft (Auergesellschaft), of Berlin, provides for the formation of a new company in England which will acquire the present English Welsbach Co., as mentioned in our last issue. The purchase price is to be £440,000, of which £240,000 will be in 4½ per cent. debentures, £100,000 in new shares, and £100,000 in cash. The object of the scheme is to bring the English, German, and Austrian Welsbach Companies under one united control, which will have the effect of obviating competition between them in the various markets of the world. The original capital of the English Welsbach Co. was £3,500,000, but this was reduced in 1903 to £1,343,975.

A CORONATION CIRCULAR

THE accompanying illustration is reproduced from the very artistic, brightly coloured front page of a leaflet relating to supply for Coronation illumination purposes, which has been prepared by the Electric Supply Publicity Committee for the use of the various supply authorities in London and the provinces. Like many of the circulars which the Committee have issued from time to time, it is a very artistic production.

Holborn Street Lighting.—The report of the sub-committee of the Works Committee of the Holborn Borough Council which, as mentioned in ELECTRICAL ENGINEERING, March 2nd, p. 110, was referred back by the Council to be considered by the Works Committee, has now been approved by the latter, and came before the Council at last night's meeting. We shall deal with the Council's decision in our next issue. The Works Committee, in presenting this report, recommend that the Gas Light & Coke Co. and the Metropolitan Electric Supply Co. be invited to tender according to the scheme contained in the report, and a new specification which has been submitted to the Council. They further propose that the term of the contract should be five years instead of ten, with an option to the Council to extend it for a further period of five years. It is suggested that the contractors should quote separate scale prices for any variations in light which may afterwards be required.

ENGINEERING EDUCATION

IN an address on February 25th, at the Municipal Technical School, Birmingham, Mr. M. Railing (Manager, General Electric Co.'s Works, Witton) raised the question of the alleged backwardness of this country in engineering matters in recent years, and dealt with what he considered to be the most important influences affecting the prosperity of the industry, namely, national policy and educational methods. He pointed out that engineering figured more largely than ever in modern life, and that it was the duty of the Government to recognise that the welfare of the people depended largely on how far their laws were consonant with engineering requirements. The ideal principle of free trade and a rivalry of perfection, even if adopted by all countries, would tend, he thought, to lead to a want of suitable employment and a lack of profitable return of capital. It could not be doubted that tariff walls would provide security for employment by freeing the home manufacturers from the anxiety of foreign competition, and making it possible to regulate prices both for labour and products. Mr. Railing further pointed out that municipal and Government contracts were often placed with foreign firms, who were not restricted by the extreme labour legislation of this country, which the municipalities and Governments would be the first to enforce had they entrusted the contracts to an English firm.

This severe foreign competition should, however, be met by thorough and efficient education. There were now in this country excellent technical schools and colleges, and it was no longer necessary to look abroad for highly trained technical men. He would advocate that employers should insist upon a guarantee, such as the passing of a certain examination, that applicants for posts had attained a certain standard of knowledge. This would afford the employer a security which at present he did not possess. That a man had passed an examination did not necessarily mean that he would be a capable and useful engineer, but, in his experience, such a guarantee was a useful guide. Mr. Railing then impressed upon his audience the importance of self-education and study on broad lines. It was necessary for the engineer to be well versed in all the factors of commercial, social, and political life, and to be capable of applying his mind in accordance with business methods. He should be acquainted with the rudiments of commercial knowledge, accountancy, business organisation, commercial law, bank practice, patent laws, &c., and able to judge commercial and social problems, and act rightly on the spur of the moment. He should be a man capable of initiative, with a knowledge of the languages and laws of other countries.

Finally, Mr. Railing outlined the responsibilities of the works manager. He must know what is the most up-to-date machinery, how to obtain the most efficient labour, the best markets in which to buy the raw materials and when to buy, and records of costs must be kept, besides the ordinary book-keeping to show the financial results of the works. Students apprenticed at works should, he said, insist on spending some time in the commercial departments of the concern, as well as going through the shops.

Amalgamation of London Electric Supply Companies.—According to the *Financial Times*, a movement is on foot for the amalgamation of certain important Electric Supply Companies in the west end of London, in connection with which it is stated that the rearrangement of the Notting Hill Electric Lighting Co.'s capital, which was sanctioned at a meeting on Tuesday, is not without interest.

Telegraph Traffic and Movements of Cable Ships.—The *via* Hanekin route was again working on the 27th ult.—The El Arich route broke down on the 1st inst., between Konia and Adana, but was repaired on the 4th inst., although there is still some delay on messages to Syria.—The CS. *Iris* is now repairing the New Caledonia cable of the French Cable Co.—The following cables, interrupted in February, still continue so:—Constantinople—Odessa, Madagascar—Réunion, Réunion—Mauritius, and Zante—Corfu.—The cable between Malta and Tripoli has been down since April 20th, 1910, and this long delay in restoring it to working order would make it appear that this section is to remain dead.—It is also difficult to understand why the owners are so long delaying operations on the following cables:—Lattaquie—Cyprus (May 24th, 1910), Tourane—Amoy (November 24th, 1910), and Teneriffe—St. Louis (October 26th, 1910), while the worst of all is the cable between Assab and Perim, down since July 8th, 1909.—The CS. *Contre Amiral Caubet*, of the French Cable Co., has repaired the St. Pierre—Brest cable off Cape Race, while the CS. *Minia*, of the Anglo-American Telegraph Co., was chartered by the Commercial Cable Co. to repair one of their sections some 150–200 miles from Newfoundland. After completing this work she went to attend to the Halifax—Rye Beach section of the Direct United States Cable Co.—The CS. *Mackay Bennett* has again returned to London from Havre, where she will have to go again to finally complete the work on the Havre—Waterville section. She will then return to her station, Halifax, N.S.

LOCAL NOTES

Australia: *Edison Battery Cars.*—The Beaumaris Tramways Co. (Melbourne) have under consideration the adoption of tramcars fitted with Edison storage batteries.

British Columbia: *Electric Railway.* — According to the *Standard of Empire*, negotiations are at present in progress with a group of United States capitalists for the construction of an electric railway from Dean Channel to Rear River, with the idea of developing the northern interior of British Columbia.

China: *Telephones.*—According to *Commercial Intelligence*, a member of the Chinese Board of Communications, which controls the telephone system in China, has been pointing out to American manufacturers of telephone apparatus the very large field there is for telephonic business in China. Perhaps the hint will also be useful to British manufacturers.

Elland: *Tramways.*—The Council, in conjunction with the Greetland Council, is considering a proposal for the National Electric Construction Co. to build a tramway from Halifax to Huddersfield, those two Corporations, together with the Brighouse Council, borrowing the necessary capital and the Tramway Company paying interest, and taking the lines on a lease for forty-two years.

Hull: *Resignation of Tramway Chairman.*—Alderman E. Robson, Chairman of the Tramways Committee, has resigned, he having differed from his colleagues with regard to the policy adopted by the Tramways Committee. The Alderman protests against the allocation of £12,000 to the relief of rates from the tramway profits, and regards the transfer of large sums to relief of rates as the wrong policy in view of the fact that the net profits have diminished during the past few years and more repairs have been found to be necessary.

Manchester: *Corporation and Westinghouse Co.*—At the last meeting of the Corporation an attempt was made to get the name of the British Westinghouse Co. struck off the list of contractors for supplying materials to the Corporation. The reason put forward was that the Company have been in conflict with some of its employees, the details of which, it is alleged, constitute a breach of the "fair contracts" Standing Order of the Corporation. After some discussion the proposal was lost by seventeen votes to seventy-seven.

Tramwaymen's Conditions.—The Board of Trade have been asked to appoint an arbitrator to decide the question of working hours and other matters over which the Council and the Tramwaymen's Union have been in dispute.

Pontefract: *Transfer of Electric Lighting Order.*—The Corporation have decided to promote a Bill in Parliament transferring their Electric Lighting Order to the Wakefield and West Riding Tramways Co. The Company is to pay £400 towards the cost of the Bill, and £150, the cost of the original order. The proposed lease is for forty-two years, with an option to the Corporation to purchase at the end of twenty-seven years.

Sheffield: *Street Lighting.*—The Watch Committee have given instructions for schemes to be prepared for lighting the Attercliffe Road either by electricity or gas.

Tramway Profits.—The Tramways Committee propose to transfer only £11,000 to the relief of rates from last year's profits, compared with £14,350 in the previous twelve months. This is not due to a decrease in tramway receipts, which, as a matter of fact, have gone up considerably, but may possibly be attributed to the prospects of extra expense upon maintenance in the near future.

Stoke-on-Trent: *Electricity Extensions.*—A special meeting of the Council is to be held to consider the proposed scheme for adopting a high-tension system of generation, at an estimated cost of £60,000. Some particulars of Mr. Yeaman's proposal were given in our last issue.

Uruguay: *Telephones.*—The Government, says *Commercial Intelligence*, have under consideration a scheme for the construction of an underground system of telephonic communication, the surveys and estimates for which are already completed.

West Bromwich: *Dispute with the Tramways Co.*—The dispute which has existed for some time between the Council and the Tramways Co. has been settled. The Tramways Co. have agreed to take a minimum of 900,000 units per annum on a sliding scale from 2d. to 1d., and there has been a revision of the allowance to be made by the Company for the repair of the track.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Burnley.—A new 1,500-kw. generating set is to be installed.

Dublin.—The proposal to borrow £128,000 for extensions of the electricity undertaking was discussed at the last meeting of the Council. It is anticipated that £40,000 will be required for additional machinery, and £54,000 for new mains, whilst the remaining £24,000 will only be borrowed should the anticipations of the Committee be borne out. The recommendation was adopted.

Felixstowe.—A loan of £2,935 is to be taken up for extensions of generating plant.

Great Harwood.—Mr. J. W. Speight has placed a proposal before the Council for introducing electricity.

Ipswich.—An inquiry was held last week into a loan of £17,000, of which £6,000 has already been expended. The new expenditure of £10,992 includes a large sum for mains extensions and for wiring, motors, and arc lamps on hire.

Kendal.—Tenders are invited by March 14th for an underground feeder. Particulars from the Borough Electrical Engineer.

Leek.—A loan of £4,000 is to be taken up for extensions at the generating station.

Liverpool.—The Corporation propose to borrow £25,000 for mains extensions.

London: *Bermondsey.*—The Finance Committee of the L.C.C. recommend sanction to a loan of £5,000 for mains and house services.

Norwich.—A battery and motor-driven booster with regulating apparatus and switchboard is required. Particulars from the Borough Electrical Engineer.

Rochdale.—Additional plant is to be installed to meet the increasing demand, especially for tramways.

Rotherham.—Tenders are invited by March 23rd for a 1,000-kw. turbo alternator, condensing plant, steam and exhaust pipes, switchboard, gallery, switchgear, &c.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

GREATER LONDON.

New elementary school at Wood Green.

Twelve houses in Semley Road, Croydon.

Buildings upon site of Nos. 70 to 78 Portland Place, St. Marylebone.

Tenders are invited for bell hanger's work in the buildings of the Commissioners of H.M. Works and Public Buildings. Particulars from H.M. Office of Works.

PROVINCES.

Barrow-in-Furness.—Fire Station.

Beckenham.—Electric theatre.

Brighton.—New school in Coombe Road.

Cork.—It has been decided to light the new school by electricity.

Derby.—Several new schools and additions to existing schools.

Durham.—Art School.

Eastbourne.—Proposed new hospital. Governors of Princess Memorial Hospital.

Glasgow.—Rebuilding of Ruskin College.

Hull.—Reconstruction of Madeley Street Baths.

Merthyr Tydfil.—Three new schools. Architect, J. Llewelyn Smith, Aberdare.

Northfleet.—New fire station at the Hill. Borough Surveyor.

Nottingham.—New Infants' School at Sutton. Notts Education Committee.

Nuneaton.—New Post Office.

Wellingborough.—New Infants' School.

Hosted by Google

MISCELLANEOUS

Aberdeen.—Track reconstruction is to be undertaken in Union Street and Holburn Street, at an estimated cost of about £500.

Bolton.—The Electricity Committee invite tenders for a twelve months' supply of various stores, including meters, motors, motor-starting switches, transformers, &c. (See an advertisement on another page.)

India.—Tenders are invited for 20-ton, 10-ton, and 5-ton electric cranes for the Bengal and North-Western Railway Co. and the Rohilkund Railway Co. Particulars from the London offices, 237 Gresham House, Old Broad Street, London.

Liverpool.—Additional cars are to be obtained, and a loan of £10,000 taken up.

London: *L.C.C.*—It is proposed to renew special track work at a number of points on the tramway system during the coming year at an estimated cost of £19,730.

South Africa.—The Rand Water Board, Johannesburg, invite tenders by April 3rd for transformers, poles, insulators, copper wire, &c. Particulars may be obtained at 73 Basinghall Street, London.

TENDERS RECEIVED AND ACCEPTED

Bacup.—A tender of Messrs. W. T. Glover & Co., Ltd., for mains, ducts, &c., has been accepted.

Blackburn.—The following tenders for a year's supply of stores have been accepted: Siemens Bros., Ozokerit tape, insulating plant, &c.; W. T. Henley's Telegraph Works Co., waterproof tape; Turners & Manville, armature insulating varnish; R. W. Blackwell & Co., insulating tape; Ferranti, Ltd., motor-starting switches; Tucker & Co., tumbler switches, fuses, lamp-holders, &c.; General Electric Co., switches; British Insulated and Helsby Cables, house service fuse boxes.

Hull.—The tender of Sir W. G. Armstrong, Whitworth & Co. at £2,180 has been accepted for the machinery in connection with the electrical working of Sculcoats Bridge.

Loughborough.—The following tenders have been received for two 350-kw. turbo alternators: Siemens Bros. Dynamo Works, Ltd., £1,700, efficiency at full load 89 per cent.; British Westinghouse Co., Ltd., £1,652 (92·5 per cent.); Phœnix Dynamo Manufacturing Co., Ltd., £1,600 (93·5 per cent.); Lancashire Dynamo & Motor Co., Ltd., £1,588 10s. (91·5 per cent.). Electric Construction Co., Ltd., £1,497 (93 per cent.); Brush Electrical Engineering Co., Ltd., £1,368 (93 per cent.); and Laurence Scott & Co., Ltd., £1,300 (91·5 per cent.). In three cases the speed is given as 3,000 r.p.m.; in two cases, 2,700 r.p.m.; in one case, 2,800 r.p.m.; and in another, 2,600 r.p.m.

Manchester.—The British Westinghouse Co., Ltd., have secured an order from the Partington Steel and Iron Co., Ltd., for four mixed-pressure "impulse type" turbo blowers for blast-furnace work and an electric generating set. The machinery in question is required for the extensive new works which the Partington Co. are erecting in the neighbourhood of Manchester.

New South Wales.—The D.P. Battery Company's tender has been accepted by the Inverell Council for a storage battery with booster.

Queensland.—The D.P. Battery Co. have secured the contract for supply of battery with automatic reversible booster and switchboard to the Toowoomba Council.

Swindon.—The tender of the Tudor Accumulator Co., Ltd., has been accepted at £138 for putting additional plates to the battery.

A number of tramcar meters are to be purchased from Messrs. Chamberlain & Hookham at £35 15s., and there is also to be a maintenance contract for five years at an annual charge of 5 per cent. on the original cost.

Messrs. Ferranti, Ltd., have received orders for tramcar meters from the Corporations of Llandudno and Plymouth. These orders are further evidence of the growing tendency of tramways authorities to fit meters to their cars.

APPOINTMENTS AND PERSONAL NOTES

Mr. L. Marshall Jockel, of Glasgow, has been appointed Assistant Manager of the Mexborough & Swinton Tramways Co.

The salary of Mr. W. T. Green, Chief Clerk in the Leeds Electricity Department, has been increased by £25 per annum.

Mr. Charles Leven, M.I.E.E., Managing Director of the Lahmeyer Electrical Co, Ltd., informs us that he has now resigned his position as Managing Director of the said Company since its absorption by the A.E.G. Co.

Mr. Leonard Llewelyn, General Manager of the Cambrian Combine Collieries, has left for a tour in Germany to study electric plant on the Westphalian Coalfields. Mr. Llewelyn will also visit some French coalfields with the same object.

Mr. H. W. Ridley has been promoted to the post of Senior Assistant in the Electric Lighting and Meter-testing Section of the Chief Engineer's Department, L.C.C., at a salary of £325, rising to £400 per annum.

The post of Station Superviser for the electric generating station at Haulbowline Dockyard is vacant. (See an advertisement on another page.)

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £57 to £57 5s. (last week, £57 5s. to £57 10s.).

Liquidations.—The Electrolytic Apparatus Syndicate, Ltd., is to be wound up voluntarily. A meeting of creditors will be held at Queen Anne's Chambers, Westminster, on March 6th, at 12.30 p.m. Mr. W. Rennison is liquidator. Particulars of claims by March 22nd.

The trustee in the bankruptcy of Frank Shepherd, electrical engineer, 4 Haslett Road, Kensington, London, has been released.

We are informed that the Lichtwerke Co. (117 Frankfurte Aller, Berlin) and the Baldurwerke Electricity Co. (6 Clausius Strasse, Berlin), both of which, we understand, are metal filament lamp firms, are in liquidation.

Canadian Agencies.—A Vancouver correspondent asks for names of manufacturers of electrical fittings, carbon and tungsten lamps, carbons, and porcelain goods.

A Birmingham firm manufacturing all kinds of electrically welded chains, rings, &c., desires to enter into correspondence with Canadian buyers. Particulars from the High Commissioner for Canada, 17 Victoria Street, London, S.W.

Wolf Locomobiles.—Messrs R. Wolf, 7 Laurence Pountney Hill, Cannon Street, London, were awarded a gold medal at the Allahabad International Exhibition for their portable and stationary patent superheated steam locomobiles.

Plant for Sale.—The Wolverhampton Electricity Committee have a number of generating sets for sale. (See an advertisement on another page.)

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Newcastle & District Electric Lighting Co.—Final dividend, making 3 per cent. for 1910, carrying forward £4,806.

Lancashire United Tramways Co.—There is a net profit of £1,188 for 1910, which has been carried to depreciation account.

W. T. Henley's Telegraph Works Co.—The net profit for 1910 was £77,556. The sum of £10,000 has been transferred to reserve, and £6,394 transferred to reserve in respect of trustee securities, after which a dividend of 15 per cent. on the ordinary shares is recommended. A balance of £27,311 is carried forward.

North Metropolitan Electrical Power Distribution Co.—The revenue for 1910 allows of a dividend at the rate of 4 per cent. per annum, with £1,500 to depreciation, carrying forward £331.

Metropolitan Electric Supply Co.—The net revenue for 1910 was £94,454, and a sum of £15,000 has been set aside for depreciation. After adding £3,500 from the undistributed balance of the Marylebone purchase money, a dividend at the rate of 5 per cent. per annum is recommended on the ordinary shares, carrying forward £771. Depreciation reserve fund now amounts to £250,355. The company have recently commenced a supply of electricity in Hanwell and Southall.

City of London Electric Lighting Co.—The net profit for 1910 was £100,790, and after meeting the 6 per cent. preference

OSRAM·LAMPS

Hosted by Google

dividend, a final dividend of 8s. per share for the December half-year is recommended, carrying forward £27,656, after transferring £4,000 to dividend equalisation fund. The special expenditure on street lighting demonstrations has amounted to £2,272, which has been placed to a suspense account for the present. The total number of units sold during 1910 show a decrease of 271,105 compared with 1909.

County of London Electric Supply Co.—The revenue for 1910 was £114,093, and after meeting debenture stock, interest, and dividends on the preference and ordinary shares, and also transferring £20,000 to reserve for depreciation, &c., there is a balance of £28,895. A dividend at the rate of 6 per cent. per annum for the December half-year is recommended, leaving a balance of £1,358. The number of units sold increased by 2,249,578 compared with 1909. The company's borrowing powers are to be increased by £200,000.

Westminster Electric Supply Corporation.—At the annual meeting last week the Chairman mentioned that the new Horseferry Road Station is now at work, and that the change over of the supply from Millbank Street had been accomplished without a hitch of any kind. He also referred to the agreement with the London Electric Supply Co., which is at present the subject of an action in the Chancery Division. In the Westminster area, he said, over 90 per cent. of the consumers were supplied by the Westminster Co., and less than 10 per cent. by the London Co., involving two sets of mains and two sets of officials to do the work which one set could do quite well. He thought the agreement would have the effect of preventing both the electric supply companies from playing into the hands of the Gas Co. We refer to the lawsuit on another page.

Newcastle & District Electric Lighting Co.—At the annual meeting last week it was stated that a large colliery pumping plant will be added to the company's mains in the course of a few weeks.

Dispute between London Electric Supply Companies.—Under the Electric Lighting Act of 1908, electric supply undertakers, for the first time in the history of the electrical industry, were allowed to "associate" for the purposes of giving a mutual supply of electricity in case of emergency, or even to transfer the management of their undertaking. Acting under these powers, the Westminster Electric Supply Corporation and the London Electric Supply Corporation entered into an agreement whereby the former should manage the undertaking of the London company in the small portion of Westminster over which it had competing powers. The agreement defines the nature of the works to be so transferred, and provides for the London company renewing and repairing the same, and carrying out any necessary additional works. The Westminster company is to pay the London company £2,000 a year to meet the standing charges of the London company for the maintenance, renewal, and up-keep of the works which are, under the agreement, placed in the hands of the Westminster company; and also a sum of 0·85d. for each unit supplied. The Westminster company is also to pay to the London company the net cost of labour and materials required for additional works and for maintaining and repairing additional mains, &c., to be provided by the London company, with the addition of 10 per cent. upon such net cost for supervision and use of tools. The agreement continues until the undertakings are purchased by the London County Council in 1931. Before Mr. Justice Joyce, in the Chancery Division last week, the London Electric Supply Corporation sought an injunction restraining the Westminster Electric Supply Corporation from committing a breach of this agreement. In the Westminster area of the London company, the management of which the Westminster company have taken over, the London company only supply alternating current, whilst the Westminster company in the same area supply continuous current. All prospective customers of the London company in this area are passed on to the Westminster company to be dealt with, and the charge is made that it has been the endeavour of the Westminster company to induce such consumers to take current from their mains, one of the arguments put forward being that alternating curent will soon cease to exist as a method of electric supply. The case was argued on Thursday and Friday, and was continued yesterday. Mr. Younger, K.C., who appears on behalf of the Westminster Electric Supply Corporation, claims that his clients are only using ordinary commercial methods in advising the use of continuous current, and that if any consumer demands alternating current, they are bound to supply it. Mr. Gore-Browne, K.C., appears for the London Electric Supply Corporation. The case was still proceeding when we went to press.

NEW COMPANIES

ASSOCIATION OF MINING ELECTRICAL ENGINEERS, Bank Chambers, London Road, Derby. Registered with 1,500 members, each liable for £1 in the event of winding up, to promote the general advancement of science in its application to the mining industry.

INTERNATIONAL SYNDICATE FOR ELECTRICAL WATER POWER CONCESSIONS: Registered by Linklater & Co., 2 Bond Court, London, E.C. Capital, £10,000.

J. H. BALLANTYNE & CO.: 80 Hyland Road, Glasgow. Capital, £1,000. Electrical Engineers and Contractors.

SIMPLEX ACME PATENT FIRE ALARM CO.: 39 Chapel Chambers North, Chapel Street, Liverpool. Capital, £1,000. To acquire from Mr. J. R. Little a patent relating to fire alarms.

INTERNATIONAL ELECTRIC CO.—Registered by Cruesemann & Rouse, 85 Gracechurch Street, London. Capital £30,000. Dealers in electric cables, wires, accumulators, lamps, telephonic and telegraphic instruments, etc. (We understand that this company is not connected with the International Electric Company of Salusbury Road, Kilburn.)

RIDINGS ARC LAMP CO., 16 Tib Street, Manchester. Capital, £3,000. Lamp manufacturers and electrical engineers.

MIDGET ELECTRIC LAMP MANUFACTURING CO.—Registered by E. Chace, Carr & Co., 11 Great Tower Street, London. Capital, £2,500. Manufacturers of lamp filaments, &c.

WATLINGTON & CO., Moorgate Station Chambers, London Capital, £5,000. To take over existing business of manufacturers and dealers in electrical goods.

ARMSTRONG, STEVENS & SON, 15 Whittle Street, Birmingham. Capital £50,000. Manufacturers of incandescent lamp sockets, telephone and telegraph wire, &c.

LORD-HOWE ELECTRICAL ENGINEERING CO.—Registered by Jordan & Sons, Ltd., 116 Chancery Lane, London, E.C. Capital £1,000. Electrical, mechanical, and ventilating engineers.

BUENOS AIRES, CITY & SUBURBAN TRAMWAYS.—Registered by Ashhurst, Morris, Crisp & Co., 17 Throgmorton Avenue, London. Capital, £500,000 (in 77,000 £5 preference shares and 115,000 £1 ordinary shares). To adopt an agreement with the Buenos Aires Port & City Tramways, Ltd.

ELECTRICAL CONDUITS.—Registered by C. Doubble, 14 Serjeant's Inn, London. Capital £5,000. Manufacturers of electrical conduits and fittings. The subscribers are B. W. and A. K. Incledon.

INTERNATIONAL RUSSIAN CORPORATION, Winchester House, Old Broad Street, London. Capital £200,000. To acquire rights to construct electric lighting systems, tramways, power installations, &c., in the Russian Empire. J. G. White is one of the directors.

F. PRICE & CO., 6/7 St. John's Square, Cardiff. Capital £2,000. Electrical engineers and contractors.

The Damp Safety Cut Out.—In an informal Paper read last month at a meeting of the Newcastle Local Section of the Institution of Electrical Engineers, Mr. G. Ralph described the working of the Holmes-Alderson automatic device for cutting off the current from electrical apparatus in mines, when the percentage of fire-damp in the atmosphere tends to reach a dangerous amount. The apparatus was fully described and illustrated in ELECTRICAL ENGINEERING IN MINES, Dec. 1st, 1910, p. cxxvi. Mr. Ralph pointed out that the device could be used as an indicator of fire-damp only in combination with one or several warning bells distributed throughout the workings. A brief discussion followed after a demonstration of the working of the device. Prof. Thornton said that the apparatus would be useful in settling disputes as to the presence of gas, and would be much more definite than the safety lamp. It would, however, he thought, suffer from the action of the hydrocarbons on the platinum. Mr. A. Barker thought that the device was hardly robust enough for use at the coal-face. Mr. Ralph, in reply, mentioned that the device could not detect the presence of coal-dust. No trouble was expected from dirt on the contacts, which consisted of two knife-edges at right angles. The surface of the platinum wire could easily be restored by raising it to a white heat, and this could readily be done.

The Marconi Wireless Telegraph Patent Case.—We are informed that the British Radio-Telegraph and Telephone Co., Ltd., do not intend to appeal against Mr. Justice Parker's judgment, delivered on February 21st, which held that the Marconi patent No. 7,777 of 1900 is valid and had been infringed. We gave the judgment on page 89 of our issue for February 23rd. We also understand that no further litigation may be anticipated in respect of the other two Marconi patents which the British Radio-Telegraph and Telephone Co. are alleged to have infringed.

SUMMARY

A SPECIAL Literary Supplement is included in this issue, containing notices and reviews of books, and a carefully revised list of selected works on electrical engineering and allied subjects.

A PAPER dealing with practical points in laying H.T. cables was read by Mr. C. Vernier at the Institution of Electrical Engineers last week, and was discussed in Newcastle and London. The author reviewed the whole subject, and described a method of straight-through jointing with copper braid, and also an expansion joint, both of which he had used with considerable success. In the Paper and discussions the relative advantages of the drawn-in, "solid," and direct-in-ground systems were discussed, the question of the need for cable-charging gear and the harmful action of vibration on cables near railways were also dealt with. (Page 135.)

Mr. L. F. MOUNTFORT'S Paper on the Electrical Undertaking of the Birmingham, Tame, and Rea District Drainage Board, read before the Birmingham Local Section of the Institution of Electrical Engineers, has been further discussed at Manchester. (Page 137.)

IN the course of an informal discussion on boilers at Sheffield last week, two new types were described. One of these, made by Hawksley, Wild & Co., is a water-tube boiler with nearly vertical tubes, and embodying a new design of tube-plate; the other, made by Fraser & Chalmers, under the Bettington patents, is fired with coal dust. Detailed descriptions of these boilers and a report of the discussion appear on page 138.

THE proposal to form a Joint Committee to acquire the Lots Road generating station, with powers to supply electrical energy to all the tube railways in London, was passed by a House of Commons Committee last week. The opposition of the London Electric Lighting Companies has been met. (Page 139.)

AMONG the Specifications published by the Patent Office on Thursday last, was one by the British Thomson-Houston Co. for a heating element consisting of a close helix of insulated resistance wire, electroplated to form a rigid metal disc. A method of cooling commutators by enclosing them in a cylindrical box to produce a circulation of air round the surface is described by the Brush Electrical Engineering Co. Two important patents relating to exhaust steam accumulators have been granted to Messrs. James Howden & Co., in spite of opposition and an appeal to the Law Officer. A patent by J. Gunning for a clockwork time-switch expires to-morrow, after its full life of fourteen years. (Page 140.)

AMONG novelties described in this issue are a fire extinguisher which is claimed to be able to deal with short circuits and petrol fires, and some new holophane reflectors. An automatic time ball is also described. (Page 141.)

THE Metropolitan Electric Supply Co. and the Gas Light & Coke Co. are to be asked to submit fresh tenders according to a new schedule and specification for the public lighting of the Borough of Holborn. (Page 141.)

EXCELLO flame arc lamps have been recommended for street lighting in Calcutta.—The District Auditor has criticised the accounts of the Marylebone Sales Department.—Nottingham traders are complaining at the high charges for electrical energy compared with

Hosted by Google

other towns of similar size.—A proposal has been made that the lines of the Dublin and South-Eastern Railway Co. should be converted to electric traction. (Page 142.)

Stoke-on-Trent Corporation have decided to proceed with a £60,000 scheme of extensions.—A loan of £1,970 is to be taken up at Barnstaple.—Electrical stores are required at Glasgow, Govan, and Wallasey.—A 600 kw. D.C. turbo-generator, &c., is required at Handsworth, two 2,000 kw. turbo-alternators at Hull, and four electric watering cars by the L.C.C.—An electric lighting scheme is under consideration at Woodbridge.—Mains are to be extended at Wednesbury.—There has been considerable comment upon the acceptance, by the Birmingham Tramways Committee, of a German tender for tramway rails. (Page 142.)

New issues of capital are being made by the Christchurch (N.Z.) Tramway Board and the Rhondda Tramways Co.—The British Insulated & Helsby Cables, Ltd., and Henley's Telegraph Works Co., have shown considerable expansion in their foreign trade during 1910.—Further generating stations for the utilisation of waste heat are being erected in the North-East Coast district. (Page 143.)

Sir John Benn's appeal against the verdict for the G.B. in the recent libel suit commenced yesterday. A report will appear in our next issue.

Telegraph Traffic.—The El Arich route was restored to normal working order on the 7th inst. On the succeeding day the line between Baghdad and Bassorah failed, but repair was effected on the 11th inst. On the 8th inst. the cable section between Djedda and Souakim was again working. As from the 10th inst., messages for Chihuahua are not accepted until further notice. No sooner was the French company's Australia—New Caledonia section restored on the 13th, when the Cayenne-Salinas cable broke down. This means the interruption of the *via* Hayti route to Brazil and South America, and more work for the *Pouyer-Quertier*. The upkeep of the French West India system must be enormous, and it seems curious that these repeated interruptions in this part of their system should occur.

ARRANGEMENTS FOR THE WEEK

FRIDAY, MARCH 17th.

Batti-Wallahs' Society.

7 p.m. Annual Dinner at Holborn Restaurant.

MONDAY, MARCH 20th.

Institution of Electrical Engineers: Newcastle Section.

7.30 p.m. At Armstrong College. Continuation of discussion on "The Laying and Maintenance of Transmission Cables," by C. Vernier.

Royal Society of Arts.

8 p.m. Cantor Lecture III. : "Applications of Electric Heating," by Prof. J. A. Fleming, F.R.S.

TUESDAY, MARCH 21st.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. At the University. "Electricity Meters," by H. A. Ratcliff and A. E. Moore.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Annual General Meeting at the Municipal School of Technology.

THURSDAY, MARCH 23rd.

Institution of Electrical Engineers.

8 p.m. "Electricity Meters," by H. A. Ratcliff and A. E. Moore.

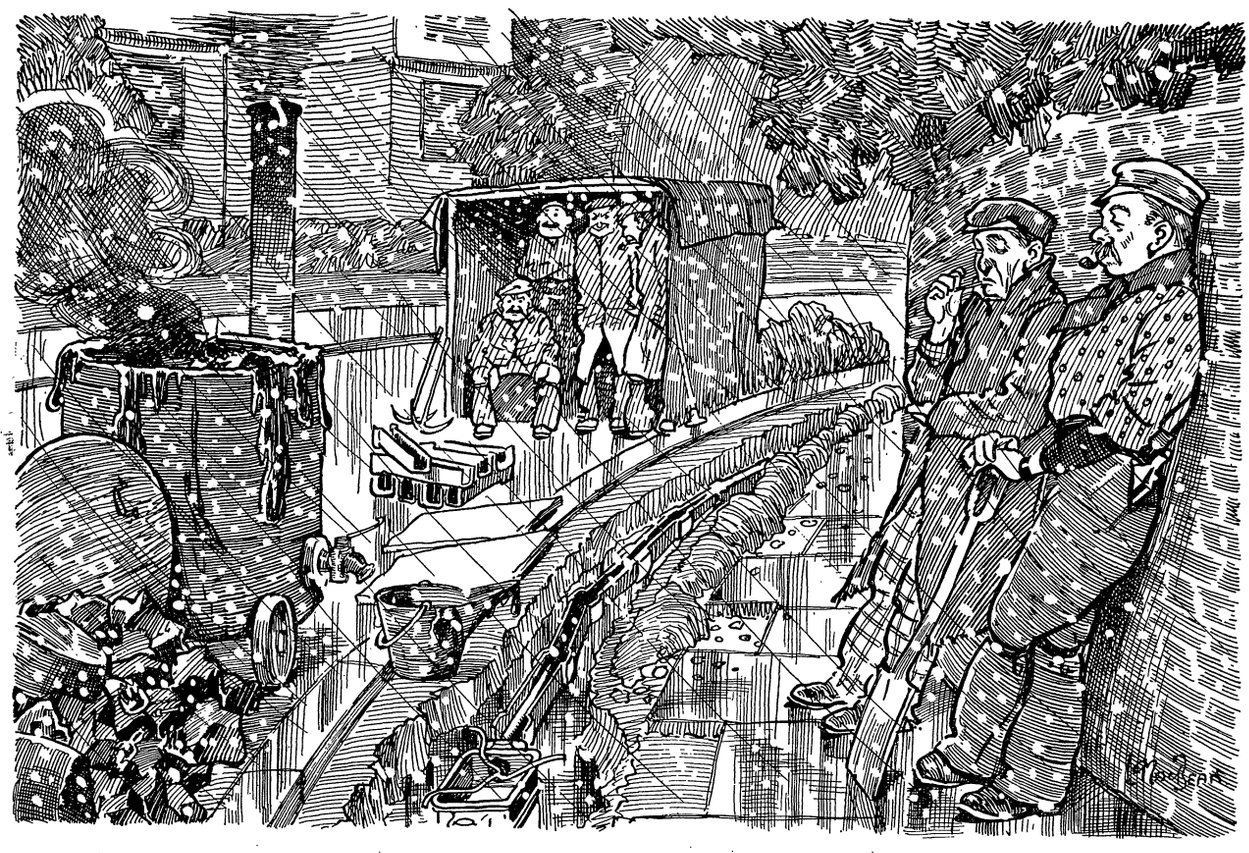
FRIDAY, MARCH 24th.

Physical Society.

5 p.m. At the City and Guilds (Engineering) College, South Kensington. (1) "Experiments on the Measurement of Electrolytic Resistances using Alternating Currents," by H. F. Haworth. (2) "Oscillatory Currents in Coupled Circuits" and "Some Radio-telegraphic Apparatus in use at the City and Guilds (Engineering) College," by Prof. G. W. O. Howe.

Institution of Civil Engineers.

8 p.m. At 25 Great George Street, Westminster. "The Uses of Chemistry in Engineering," by Mr. James Swinburne.



Electro Harmonic Society.

8 p.m. Smoking Concert at Holborn Restaurant.

SATURDAY, MARCH 25th.

Association of Mining Electrical Engineers.

3.30 p.m. *Notts and Derbyshire Branch.* At University College, Nottingham. (1) "The Use of a Milli-ampere Testing Set," by E. E. Beadsmore. (2) Discussion on the new Home Office Regulations.

In the course of a paper on the laying of cables read before the Institution of Electrical Engineers last week Mr. C. Vernier said :—"The solid system . . . has many objections . . . the chief of which is the difficulty of getting the work done satisfactorily under adverse conditions of weather, and similar inconveniences encountered when carrying on out-door work on a large scale."

"ELECTRICAL ENGINEERING"

LITERARY SUPPLEMENT

NEW PUBLICATIONS

We shall be pleased to send any of the undermentioned works to addresses in the United Kingdom, at the net prices quoted. The price for sending to the Colonies and abroad is also quoted when there is an increase. Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203–6 Temple Chambers, Temple Avenue, London, E.C., accompanied by a remittance.

"Electric Wiring, Fittings, Switches, and Lamps: Circuits," by W. P. Maycock. 4th edition. 628 pp. 7¼ in. by 5 in. 624 figures. (London: Whittaker and Co.) 6s. net; abroad, 6s. 8d.

"The Elements of Telephony." By A. Crotch. 90 pp. 7½ in. by 4¾ in. 51 figures. (London: E. & F. N. Spon.) 1s. 6d. net; by post, 1s. 7½d.

"Practical Electricity." By Prof. W. E. Ayrton and Prof. T. Mather. 3rd edition. 539 pp. 8¾ in. by 5¾ in. 289 figures. (London: Cassell & Co., Ltd.) 9s. net; abroad, 9s. 10d.

"Electric Wiring Diagrams." By W. P. Maycock. 146 pp. 5 in. by 7¾ in. 246 figures. (London: Whittaker & Co.) 2s. 6d. net; abroad, 2s. 9d.

REVIEWS OF BOOKS

Practical Electricity. By Prof. W. E. Ayrton and Prof. T. Mather. 3rd edition. 539 pp. 8¾ in. by 5¾ in. 289 figures. (London: Cassell & Co., Ltd.) 9s. net; abroad, 9s. 10d.

BEFORE Prof. Ayrton's death, the decision had been arrived at that an enlarged edition of his well-known *Practical Electricity* should be published under the joint names of himself and his colleague and now successor, Prof. Mather. Upon no one better than him could it have devolved to finish the task, and we take up the result of his labours with great interest. In many ways, the rapid advance of electrical science has necessitated some bringing up to date, but there is much of Prof. Ayrton's original work of as permanent a character as the principles themselves which he expounded. The book at the time of its original production in 1886 broke much new ground; not only was the subject young, but the author was the pioneer in striking out what was then a new method of teaching it. The idea underlying the system can be no better presented than in the words of the original preface again quoted in the re-written edition of 1896:—

> Readers . . . will be surprised at the arrangement of the subjects in this book . . . the order in which they have been arranged has been a matter of most careful consideration, and has been arrived at by what appears to me to be the *natural*, as distinguished from the *scholastic*, method of studying electricity. I have endeavoured to treat the subject analytically rather than synthetically, because that race of successful experimenters—children—adopt this method.

This was the keynote to the whole system, and there are few, if any, works that carry out this educational ideal so consistently.

The book is essentially a text-book and laboratory guide for a first-year student who desires to take up "Practical Electricity" as a business or profession, and to avoid misunderstanding and disappointment, we should point out that it does not attempt to be "practical" in the sense of dealing with the latest practice in industrial applications, which is, of course, a more advanced part of the subject. Industrial appliances are, however, brought in where convenient to illustrate principles, but even if the dynamo and motor are not included in the first year's course, yet they should not have been omitted entirely from a first text-book on "Practical Electricity."

The chief directions in which Prof. Mather has expanded the treatment, besides the general painstaking revision, are in greater detail in the connection between electrical and mechanical quantities, new chapters on the potentiometer, induction of currents, and on the magnetisation of iron. More space is devoted to integrating meters, and new wire tables are given.

Elementary Principles of Alternating-current Dynamo Design. By A. G. Ellis. 300 pp. 8¾ in. by 6 in. 145 figures. (London: Blackie & Son.) 12s. net; abroad, 12s. 8d.

As mentioned in the preface, the greater part of this work was prepared during the period in which Mr. Ellis, who is now designer to the Elektrizitäts Gesellschaft Alioth, Basle, was associated with Mr. H. M. Hobart; thus the book is practically a companion to Mr. Hobart's *Continuous-current Dynamo Design*. The treatment in the present volume is very similar, a practical system of design being developed from first principles and on constants obtained from modern practice. Emphasis is laid upon the general influence of the various principal factors, such as speed, output, frequency, and voltage, and proportion, economy, and cost are carefully studied throughout. The text is concise, and accompanied by useful tables, schedules, and curves. Complete data with drawings are given of typical alternators of moderate speeds, accompanied in some cases by sketches of mechanical details and test curves. The special features in the design of turbo-alternators are also dealt with. Students will find the work a clear and reliable text-book of practical design, while the data and constants should be of considerable value to those already engaged in the design of alternating-current machinery.

Solenoids, Electromagnets, and Electromagnetic Windings. By C. R. Underhill. 342 pp. 9 in. by 5¾ in. 223 illustrations. (London: Constable & Co.) 8s. Abroad, 8s. 9d.

THE spreading developments of remote and indirect control of switchgear, of which examples are found in automatic starters in relays of all kinds and in the contactors which form a feature of multiple-unit traction systems, has caused the design of electromagnets and solenoids for definite and predetermined action to be a matter of much more moment than formerly. The author of this book has had these requirements in mind, and it has been his object to provide a study of the subject leading up to and including data for the design of such apparatus. The treatment has a completeness such as we do not remember to have seen elsewhere, and the many practical points both as regards electrical design and mechanical construction of electromagnets and solenoids, for continuous as well as for alternating currents, are evidently the results of experience. In the niceties of electromagnetic control, the United States have certainly led the way in the past, and it is not surprising that this work hails from the other side of the Atlantic. The scheme does not include the description of apparatus worked electromagnetically. All that is presented is a connected study of the influence of the proportions of the dimensions, and the nature of the windings upon the magnetic action produced with formulæ deduced from both theoretical and test results, together with full data, wire tables, &c., for the design of windings for any requirements. It will perhaps cause inconvenience to some engineers in this country that the Brown & Sharpe gauge is used in the tables, but the comparative tables of other gauges go far to remove this objection.

Hosted by Google

Applied Thermodynamics for Engineers. By W. D. Ennis. 438 pp. 10 in. by 6¼ in. 316 figures. (London: Constable and Co.) 24s. net; abroad, 25s. 3d.

THE author aptly defines his standpoint in his preface, where he says, "This book takes a middle ground between those text-books which replace all theory by empiricism, and that other class of treatises which are apt to ignore the engineering significance of their vocabulary of differential equations." He does not shirk mathematics, but commendably avoids complication in his treatment. A presentation of the fundamental principles of the thermal and mechanical behaviour of gases, admirable in its clearness and logical sequence, is given in the earlier chapters, while the body of the book proceeds to apply the principles to the development of methods of investigating and understanding the phenomena met with in engineering. Compressed air is treated at more length than is usual in such works, and the gas engine, steam engine, steam turbine, and refrigerating plant are dealt with in turn. A brief chapter discusses some aspects of boiler-house plant. The book is in no way a treatise on design, but no designer in these days of progress can afford to be ignorant of the scientific side of the subject, which is here presented in a way preserving a nice balance between the pedantic and the empirical.

The whole of this work reflects great care in its compilation, and such details of its arrangement as the paragraphs being divided and printed in varying sizes of type according to their importance, and the presence of a summary of its contents at the end of each chapter enhances its utility. The problems following each section also appear well chosen.

Elementary Telegraphy. By H. W. Pendry. 216 pp. 7½ in. by 4¾ in. 200 illustrations. (London: Whittaker and Co.) 2s. 6d. net.

THIS useful little text-book has been written to meet the requirements of the ordinary grade examination of the City & Guilds of London Institute. In the first chapter, the author summarises the elementary principles of electricity and magnetism, but the student of the following pages should have had some further instruction, as the subject is treated purely in its relation to telegraphy. After a section on primary and storage batteries, the various instruments used in telegraphy are clearly described with the aid of numerous diagrams and excellent half-tone illustrations of modern apparatus. Telegraph lines are then dealt with, the various patterns of insulators and poles and methods of erection being described. Dry-core cables for underground lines, and submarine cables are only briefly referred to. A few pages are devoted to testing, and, finally, the various methods of operating are carefully explained, including the different central battery systems and their recent applications. Test questions are appended to each chapter.

The Telegraphic Transmission of Photographs. By T. Thorne Baker. 146 pp. 7½ in. by 5¼ in. 64 illustrations. (London: Constable & Co., Ltd.) 2s. 6d. net; by post, 2s. 8d.

WRITTEN for the general reader rather than for those acquainted with telegraphic work, the descriptions of the various systems of phototelegraphy contained in this book are mainly in non-technical language. The author explains the principles of the Korn selenium and telautograph systems, as well as other methods,, and describes the difficulties met with in the development of a practical system for the *Daily Mirror*. In parts the text is highly technical, as when explaining the compensation of selenium cells. The author's own apparatus, the telectograph, is described, and some preliminary experiments in the wireless transmission of pictures are referred to.

Industrial Pyrometry. By C. R. Darling. 30 pp. 10 in. by 6¾ in. 23 figures. (London: Royal Society of Arts.) 1s. net; abroad, 1s. 2d.

THIS is a series of four Cantor lectures delivered before the Royal Society of Arts in November and December, 1910. The first lecture covers the history of high temperature measurement, and the use of pyrometers in the manufacture of pottery, glass, iron, and steel, coal-gas, &c. The principles and the most modern forms of the three types of instruments, viz., thermoelectric, resistance, and radiation pyrometers, are described in the remaining three lectures.

BLACKIE & SON'S LIST

ELEMENTARY
PRINCIPLES of ALTERNATING CURRENT DYNAMO DESIGN
By A. G. ELLIS, A.C.G.I., A.M.I.E.E., A.Am.I.E.E.
Illustrated. Demy 8vo, cloth. Price 12s. net

ELECTRICAL ENGINEERING MEASURING INSTRUMENTS
FOR COMMERCIAL AND LABORATORY PURPOSES
By G. D. ASPINALL PARR, M.Inst.E.E., A.M.I.Mech.E.
Associate of the Central Technical College, City and Guilds of London; Head of the Electrical Engineering Department, Yorkshire College, Victoria University.
With 370 Illustrations. Demy 8vo, cloth, 9s. net

ELEMENTARY
ELECTRICAL ENGINEERING
By JOHN H. SHAXBY, B.Sc.
Demonstrator and Assistant Lecturer, University College of South Wales, Cardiff.
PROFUSELY ILLUSTRATED WITH PHOTOGRAPHS AND DIAGRAMS.
Crown 8vo, cloth, 3s. net

ELECTRICAL LABORATORY COURSE
FOR JUNIOR STUDENTS
By R. D. ARCHIBALD, B.Sc., A.M.Inst.C.E., Lecturer in Engineering, Technical Institute, Dundee.
AND ROBERT RANKIN, A.G.T.C., Stud.I.E.E., Formerly Assistant to the Professor of Electrical Engineering in the Glasgow and West of Scotland Technical College.
Crown 8vo, cloth, 1s. 6d. net

MAGNETISM and ELECTRICITY
AND
THE PRINCIPLES OF ELECTRICAL MEASUREMENT
By S. S. RICHARDSON, B.Sc.
Associate of the Royal College of Science, London. Lecturer in Physics, Municipal Technical School, Liverpool.
Crown 8vo, cloth, 5s. net

A MANUAL OF
RULES, TABLES, AND DATA
FOR MECHANICAL ENGINEERS
By DANIEL KINNEAR CLARK, M.Inst.C.E., M.I.M.E.
Honorary Member of the American Society of Mechanical Engineers; Author of "Railway Machinery" "Tramways: Their Construction and Working", &c.
Demy 8vo, cloth, 16s.; half-morocco, 20s.

Prospectuses giving full particulars of above Books post free on application.

BLACKIE AND SON, LIMITED,
50, OLD BAILEY, LONDON.

Hosted by Google

Drying Machinery and Practice. By Thomas G. Marlow. 326 pp., 9 in. by 6 in., 174 illustrations. (London: Crosby, Lockwood & Son.) Price 12s. 6d. net; by post in U.K., 13s.; abroad, 13s. 6d.

THIS is a well-written book on a subject regarding which little has hitherto been published in a collected form. The principle and construction of drying machinery are fairly well covered in the eleven chapters, and good illustrations are included, but electrical engineers will be disappointed that more information is not given with regard to the patterns of vacuum dryers employed in cable manufacture, and for drying and impregnating coils for electrical machinery. The design, construction, and application of the vertical shaft electric motor for that type of drying machine known as the "hydro-extractor," also merits more extended treatment than is accorded to it.

The Electrical Ignition of Petrol Engines. By J. W. Warr. 76 pp., 7¼ in. by 4¼ in., 60 figures. (London: H. Alabaster, Gatehouse & Co.) 2s. net; by post, 2s. 1½d.

IT has been the object of the author to supply a handbook for the use of persons in charge of motor cars who are not familiar with things electrical, but as ignition is such a very specialised branch of electrical work, there is a good deal that will be found useful to electrical men unfamiliar with motor cars. Such first principles as are required are put with sufficient clearness, the leading coil and magneto systems are explained, and various practical hints are given. On the whole, the work is accurate and reliable, but we do not like the author's proposed method (page 11) of charging cells in parallel, as cells in varying conditions will not share the current equally. A mistake has also been made on page 64 in referring to the diagram of the Bosch dual ignition system on the previous page as using the magneto windings as a coil with a battery. This is not the case, as a separate coil is provided on the dashboard. The diagram does not represent quite the latest pattern of the apparatus, but this does not detract much from its value.

Electric Railways. By J. R. Cravath and H. C. Trow. 153 pp. 9½ ins. by 6½ ins. 120 figures and illustrations. (American School of Correspondence of Chicago.) (London: Crosby Lockwood & Son.) 4s. 6d. net; abroad, 5s.

THIS is one of a series of sixty volumes prepared by the American School of Correspondence of Chicago, and the greater part is the work of Mr. J. R. Cravath, the Western Editor of *The Street Railway Journal*. It is in the main descriptive, and forms a very readable and instructive introduction to the problems met with in electric traction. Unfortunately, however, the text deals almost entirely with American practice and conditions, and although the electrical equipment is very similar, the general conditions and the construction of the rolling stock and permanent way are quite different in this country. Again, most of the text refers to interurban railways, of which we have comparatively few. The information with regard to heavy main line traction is somewhat out of date, in spite of the fact that a short section on single-phase railways has been added since the main portion was prepared.

Power and its Transmission. By Thomas A. Smith. 76 pp. 6½ in. by 4 in. (London: E. & F. N. Spon.) 2s. net by post in U.K., or abroad, 2s. 2d.

EVIDENTLY written by one who has had some considerable experience with shop driving, this little volume contains a great deal of practical information regarding the proper dimensions, arrangement, and care of belts, shafting, and rope drive, the choice and testing of lubricating oil, &c. A chapter on the gas engine is too short to be of much value, and refers to tube ignition only. The notes on electric driving are of an exceedingly elementary character, merely explaining in a non-technical manner the purpose of switches and fuses, and giving a few general hints as to the management of a motor. The glossary of some fifty electrical terms will be useful to some readers.

The Care and Management of Ignition Accumulators. By Harold H. V. Cross. 66 pp. 7½ ins. by 5 ins. 12 figures. (London: E. & F. N. Spon, Ltd.) 1s. 6d. net; by post in U.K. or abroad, 1s. 7½d.

THE first part of this little work contains information which should be of use to motor-car owners, cycle agents, and motor-car repairers, and others who have to look after the charging of ignition accumulators without the help of a skilled electrician, but we do not think that the second part would appeal to quite so many. It describes a cheap and rather makeshift method of house lighting with what is little more than a toy gas engine and dynamo, an eight-volt battery, and switchgear of too primitive a nature to be reliable.

JUST READY. In medium 8vo, Handsome Cloth, pp. i–xx+313, with 366 Figures and 23 Tables. 25s. Net.

ELECTRIC CRANE CONSTRUCTION

(Cranes, Cableways, Transporters, Sheer Legs, &c.)

By CLAUDE W. HILL, A.M.Inst. C.E., M.I.E.E., M.I.M.E.

Detailed Prospectus post free on application.

JUST PUBLISHED. In large 8vo, Handsome Cloth, pp. i–xiv+356, with 18 Plates and 332 Figures. 21s. Net.

TRANSFORMERS

A Treatise on the Theory, Construction, Design, and Uses of Transformers, Auto-Transformers and Choking Coils,

By HERMANN BOHLE, M.I.E.E., &c. Professor of Electro-Technics, S.A. College, Cape Town, and DAVID ROBERTSON, B.Sc., A.M.I.E.E., &c., Professor of Elect. Eng. in the University of Bristol.

Detailed Prospectus may be had post free on application.

LONDON: C. GRIFFIN & Co., Ltd., EXETER STREET, STRAND

LEWIS'S CIRCULATING SCIENTIFIC LIBRARY

Comprises a large collection of Scientific and Technical works dealing with Electricity, Engineering (Electrical, Mechanical and Civil), Metallurgy, Chemistry, Geology, Physics, etc., etc.

The library is invaluable to Electrical Engineers desiring to consult works on their own or allied subjects.

Annual subscription Town or Country from one guinea.

Reading Room open daily to subscribers.

Lewis's Quarterly list of New Books and New Editions added to the Circulating Library, with nett prices and postages, will be sent post free on application.

Electric Circuit Problems in Mines and Factories. By Ellis H. Crapper. 159 pp. 6½ in. by 4¼ in. 57 figs. (London: "Colliery Guardian.") 3s. 6d. net.; by post in U.K. or abroad, 3s. 8d.

THIS handbook, which is small enough for the pocket, would have been of enormous value to the colliery electrician if only it had been a little better. As an instance of the sort of thing that spoils it, we may take one numerical example which we noticed on opening the book at hazard. The case taken is an installation of fifty 60-watt carbon-filament lamps and a 20-B.H.P. motor 1,000 yards from the dynamo. A voltage of 250 is assumed, and the current required is first calculated, then the section of the cable from the formula $C=2{\cdot}6A^{0{\cdot}42}$ with the aid of logarithms, and the nearest cable to this section is found from a wiring table (which obviously would have given the cable at once without the necessity of a calculation and the employment of a table of logarithms). The drop of pressure at full load is then worked out and found to be 49·6 volts, and 300-volts is therefore recommended as the voltage for the dynamo; the reader is told that "it will be advisable to use an over-compounded generator." Further, in a small book such as this, written by the Head of the Department of Electrical Engineering at the University of Sheffield, and issued by a technical publisher, we do not expect to find a list of six errata at the beginning—a list which, moreover, does not include all the mistakes.

Theoretische und experimentelle Untersuchungen an der synchronen Einphasen-Maschine. By Max Wengner. 88 pp. 9¾ ins. by 6½ ins. 44 figures. (Munich: R. Oldenbourg.) 2s. 6d. net; by post in U.K., 2s. 10d.; abroad, 3s.

IN view of its adoption in connection with railway electrification on the single-phase system, the single-phase generator deserves more consideration than it has had in the past. The present work contains a thorough mathematical investigation into the theory of the machine, and, in particular, into the effects of the so-called inverse field, namely, the backwards rotating component of the two rotating elements into which the pulsating armature field may be resolved. The author concludes that the circle-diagram as applied to single-phase generators gives reasonably accurate results, except where the armature strength is exceptionally large. An approximate method is given for estimating the currents in the damping-coils which are placed in the pole-shoes to prevent distortion of the wave form by the inverse field.

Elektromotorische Antriebe. By B. Jacobi. 341 pp. 8¼ in. by 5½ in. 172 figures. (Munich: R. Oldenbourg.) 8s. net; by post in U.K., 8s. 4d.; abroad, 8s. 7d.

This volume is a compendium of all the various types of electric motors, and the different methods of control and the apparatus required. It is essentially a book of reference for the consulting or works engineer, and should be of assistance in the choice of motor and control apparatus. The arrangement of the information facilitates reference. The merits and demerits of alternative types of motors and control gear are tabulated, and a long list of industrial machines and machine-tools is given, with the probable horse-power required. The choice of system and voltage, mechanical drive, and other details are briefly discussed, and some chapters are devoted to the design of works installations and the calculation of the rating of motors for certain specified cases.

Practical Telephony. By J. Bell and S. Wilson. 5th edition. 306 pp. 7¼ in. by 4¾ in. 232 figs. (London: S. Rentell & Co.) 3s. 6d. net.

THE matter in this book is good, but the arrangement is bad. In revising it for the present edition, the authors have shown excellent judgment in collecting technical descriptions of exchanges and other material and apparatus from technical journals, but they have displayed no skill in piecing them together. The result will be highly perplexing to the student, who will find a great part of the book unintelligible to him. Yet both of the authors are teachers, and the book is, according to the title-page, adapted to the requirements of the City and Guilds of London Institute and the Post Office Department Examinations. The book concludes with some of the City and Guilds examination papers on telephony, and these afford an effective test of the inadequacy of the book, for a large proportion of the questions could not possibly be answered by information to be found in its pages.

Aeroplane Patents. By R. M. Neilson. 90 pp. 8½ in. by 5½ in. 77 figures. (London: Constable & Co., Ltd.) 4s. 6d. net; abroad, 4s. 9d.

THE author has collected together here the subject matter of the most important British aeroplane patents. The work is in no way critical, and a great deal of the space is devoted to descriptions of devices of questionable utility. For those experimenting, however, it should be of use as telling them what must be avoided if originality is to be claimed.

The Slide Rule, by C. N. Pickworth. 12th edition. 118 pp. 7¼ in. by 5 in. 34 figures. (Manchester: Emmott & Co.) 2s. net; by post, 2s. 3d.

THE twelfth edition of this well-known handbook to the slide rule is made even more complete than former editions by the addition of descriptions of one or two new forms of slide rule, including one by the author, upon which a scale of cubes is marked. Some additional remarks on the use of special gauge points are also given.

Logarithms for Beginners. By C. N. Pickworth. Third edition. 47 pp. 7¼ in. by 5 in. (Manchester: Emmott & Co.) 1s. net; by post, 1s. 2d.

THIS well-known text-book on logarithms, now in its third edition, is noted for the concise and lucid manner in which the methods and reasons of the various operations are explained, and is particularly suitable for self-instruction. The careful arrangement of the text and the use of heavy type for important rules, &c., are especially helpful. With the exception of some slight revision and the correction of a few numerical errors, the book is in its original form.

Universal Electrical Directory, 1911. 1,552 pp. 9¾ in. by 6¼ in. (London: Alabaster, Gatehouse & Co.) A. British and Colonial Sections only, 10s. B. British and Colonial, with Continental and U.S.A. Sections, 14s. 6d.

A NEW arrangement which has been introduced into the 1911 edition of the familiar Red Book is the separation of the London from the provincial names in the British alphabetical section; a radius of fifteen miles from London is taken for this purpose. For the rest, the directory contains all the old and invaluable features which render the book indispensable to everybody in the electrical industry. The present constitutes the thirtieth edition.

The Faraday House Journal.—A copy of the February issue of the *Faraday House Journal* has just come to hand. Amongst other things, it contains four technical articles by old students of the Electrical Standardising, Testing, and Training Institution on subjects of current interest, including some notes on pyrometry by H. G. Weaver, a note on resistances for horn type pressure limiters by H. W. Swann, and articles on faults in direct-current machines and on three-phase transformers by F. C. Topham and J. Goodman respectively. A notable feature is the long list of appointments obtained by students on leaving Faraday House on the completion of their course, and it is interesting to note that every Faradian who left at the end of the past two terms has already found a post.

"ELECTRICAL ENGINEERING" LIST OF SELECTED TECHNICAL BOOKS.

We shall be pleased to send any of the following books to addresses in the United Kingdom at the *net* published prices named, unless otherwise stated. The increased price for sending abroad is also quoted after each book. All the books listed have been recommended by our editorial staff and reviewers.

Orders should be addressed to the Kilowatt Publishing Co., Ltd., 203-206 Temple Chambers, Temple Avenue, E.C., and should be accompanied by a remittance.

CASSELL'S
WORKS ON ELECTRICITY

PRACTICAL ELECTRICITY.
By the late Prof. AYRTON and THOMAS MATHER, F.R.S., M.I.E.E. Demy 8vo, 576 pages. Cloth, **9s.** net.
This book has been carried out mainly upon Prof. Ayrton's own lines, embodying his famous natural method of instruction as distinguished from the mode of the mere scholastic primer.
Its utility is enhanced by important wire and winding tables in the Appendix, some of which, originally calculated by Prof. Mather, are now published for the first time.

ELECTRICITY IN THE SERVICE OF MAN. FIRST VOLUME.
By R. MULLINEUX WALMSLEY, D.Sc. (Lond.), F.R.S.E. Profusely illustrated. Cloth, **7s. 6d.** net.
"We have pleasure in recommending it to that large class who are yet desirous of an intelligent acquaintance with its apparatus and phenomena." —*Mechanical Engineer.*

ELECTRICAL DISTRIBUTING NETWORKS AND TRANSMISSION LINES.
By ALFRED HAY, D.Sc., M.I.E.E. With over 100 Diagrams and Illustrations. Demy 8vo. Cloth gilt, **10s. 6d.** net.
"Thoroughly up-to-date, can be recommended for its utility. It is the best we know of its kind." —*Practical Engineer.*

ELECTRICAL ENGINEERING.
By HAROLD H. SIMMONS, M.I.E.E. With numerous Diagrams and Illustrations. Cheap Edition. **12s. 6d.** net.

NOTES ON ALTERNATE CURRENTS FOR STUDENTS. By HAROLD H. SIMMONS, M.I.E.E. Illustrated. Paper covers, **1s. 6d.** net.

CASSELL & CO., Ltd., La Belle Sauvage, London, E.C.

CABLE LAYING AND JOINTING

A PAPER on "The Laying and Maintenance of Transmission Cables" was read by Mr. C. Vernier before the Newcastle Section of the Institution of Electrical Engineers last week, and also at the London meeting. The author estimated that the mains system represents from 30 to 50 per cent. of the total capital expenditure on an electric supply undertaking, and that the capital expenditure on mains of all kinds in the United Kingdom is probably not less than £25,000,000. He confined his remarks to three-phase underground transmission cables, for pressures between 6,000 and 20,000 volts.

Dealing with the draw-in system first, he expressed his preference for single pipes rather than multiple-way ducts to meet the event of a short circuit occurring in the ducts. As accidents have occurred from manhole covers being dropped on to cables, he recommended the arrangement illustrated in Fig. 2, in which the pipes are gradually

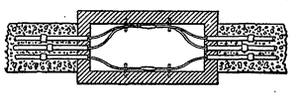

Fig. 1.—Common Arrangement of Cables in Manhole.

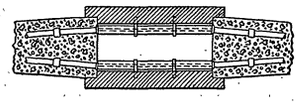

Fig. 2.—Recommended Arrangement of Cables in Manhole.

splayed out as they approach the manholes, to the more usual arrangement shown in Fig. 1. In a draw-in system, he continued, cables are liable in certain cases to damage by chemical action from bad water draining into the ducts from the surrounding soil, and as the pipes are frequently wet, electrolysis is greatly facilitated. From these points of view cast-iron pipes, where their cost is not prohibitive, are to be preferred, as they can be made much more easily watertight by means of leaded joints. The cables should be bonded to the pipes in a substantial manner at each manhole, and any electrolytic corrosion likely to occur will take place on the pipes. In earthenware pipes or ducts, it is preferable to use wire-armoured cables, the armouring taking the place of the copper tape B.O.T. earth sheath under the lead. Failing this, it is an advantage to use cable taped and braided over the lead sheath, as a protection against corrosion. The armourings and lead sheaths should be carefully bonded together, and earthed to an earth-plate at each manhole. On the question of repairs, he pointed out that, in the draw-in system, it is necessary in every case to draw in a whole length of cable between manholes in order to effect a repair, whereas on a solid system cases seldom occur where it is necessary to insert more than a few yards of cable.

Coming next to the solid system, he said that there is very little difference in the cost of wood and earthenware troughing, and in many cases earthenware troughs, which are more lasting than wood, and may be expected to outlast any cables, can be obtained more cheaply. Wood troughing, if used, should be boiled in Stockholm tar, not merely soaked or painted with the cold tar. When creosoting is ordered, the only satisfactory treatment is to impregnate the timber with creosote under pressure, as is done in the case of telegraph poles. Creosote obtained as a by-product of coal-tar distillation, if otherwise free from foreign matter, has no action upon lead or iron, but wood creosote obtained in the distillation of wood must be carefully avoided. Wood troughing is not brittle like earthenware, and can be obtained in much longer lengths, thus decreasing the number of trough joints, but the author thinks that these features are its only advantages, and that earthenware troughing is much to be preferred, except for situations where much vibration is to be expected, as in the case of cables laid along railways. Fig. 3 shows the wrong way to construct wood troughing, and Fig. 4 the right way. In the latter, it will be observed that the weight of the soil on the side-pieces is distributed on the bottom piece.

Earthenware troughing should be well glazed outside, but left unglazed inside, as the pitch or bitumen does not adhere to a glazed surface. The chief objection to earthenware troughing is the short lengths (about 2 ft.) in which it has to be manufactured, but in good ground this gives no trouble. Cast-iron troughing is expensive, but makes a thoroughly sound system, provided that, in addition to the troughs being bolted together, the lead sheath and armouring is well bonded to the troughs at intervals. In some cases iron supporting bridges are used, which grip the cable and are screwed to the iron troughs.

The filling compound for the troughs is usually refined pitch, or, less frequently, Trinidad bitumen. The latter is two and a half to three times as costly as pitch, but there can be no doubt of its superiority for cable laying. Pitch in its natural state is too brittle, and has to be mixed in suitable proportions with a thinning oil in order to render it more plastic. Unless great supervision is exercised in the mixing, the pitch will be too brittle, and from his experience the author inclines to the opinion that pitch which has been put into the troughs mixed with thinning oil in such proportions as to be quite plastic, does not retain this property indefinitely.

The weakest part of the solid system is the supporting bridges for the cables.

Wood should never be used in contact with the lead sheath of cables, as in its decay, which must inevitably occur sooner or later, organic acids are produced which attack lead. Oak is particularly bad in this respect. Cable bridges should therefore be made of earthenware, china, asphalte, or some other material not subject to absorption of moisture or to decay, and which is chemically inert. All bushes required at trough and pipe ends should be of glazed earthenware, and all organic materials, such as canvas, waste, &c., should be strictly kept clear of lead sheaths. Certain makes of cement also act chemically upon lead, and some engineers who have used conduits consisting of cement-lined steel tubes have experienced trouble from this cause. Asphalte bridges have the advantage that the hot filling composition softens their surface and thus adheres very closely to them. This property is sometimes a disadvantage with heavy cables, as the bridges are liable to soften sufficiently to be crushed out of shape by the weight of the cables. For heavy transmission cables the author prefers glazed earthenware bridges, and, in order to ensure the adherence of the filling composition, it is his usual practice to prepare the bridges by dipping them when dry in a fluid mixture of pitch and thinning oil, with which they become coated. Figs. 5 and 6 show designs of cable bridges, from

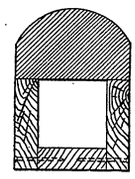

Fig. 3.—Wrong Way of Making Trough.

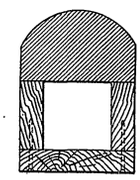

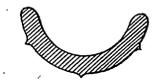

Fig. 4.—Right Way of Making Trough.

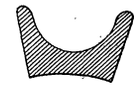

Fig. 5. Fig. 6.

Bridges for Solid System.

which it will be noticed that the surfaces in contact with the troughs are reduced to mere points, so as to allow the filling composition entirely to surround them. Cables with a braided covering, the author said, are much to be preferred, as the filling composition adheres very closely to such braidings, or, better still, armoured and jute served cables laid solid in bitumen.

A good hard-pressed dome-shaped tile about 3 in. thick cannot be excelled as a protective covering for transmission cables, whether laid in wood, earthenware, or cast-iron troughing. Cast-iron covers, about ¼ in. thick, such as are often used, do not offer sufficient protection to a blow from a sharp pick. It is a good plan to have the tiles stamped either with the name of the owners or with the word "electricity," which act as a warning to excavators of what the troughing contains.

The solid system is not, in the author's opinion (who has had some twelve years' experience of it), a thoroughly practical system to use for transmission work or any similar work on a large scale; the practical difficulties in obtaining good workmanship in the conditions under which the work has to be carried out are very great, particularly in our uncertain climate. A shower of rain will frequently saturate everything, while in dry, windy weather dirt gets blown into the troughs. In waterlogged ground it is practically impossible to obtain good work, and owing to the shrinkage of the filling compositions the greatest care has to be exercised in order to get the troughs full and also free from blow-holes.

Hosted by Google

For transmission cables laid direct in the ground, the author prefers wire armoured cable protected either by tiles or creosoted planks about 2 in. thick, laid directly over the cables with about 3 in. of soil in between. Planks are less liable to be displaced. The author attributes the popularity of the solid system in this country almost entirely to some very rapid failures of armoured cable systems which have been experienced in the past. Armoured cables laid in dry sandy soils give very good results, while similar cables laid in made-up ground where decomposition of organic matter is liable to occur, or in ashes or in ground charged with sewerage matter, sometimes fail within a year or two, and in some cases even more rapidly. Clay has been said to affect armoured cables injuriously, but this has not been the author's experience. [Clay has, however, been known to act injuriously on the lead covering of cables.—ED. *E.E.*]

The solid system has many objections for transmission work on a large scale, the chief of which is the difficulty of getting the work done satisfactorily under adverse conditions of weather and similar inconveniences encountered when carrying on outdoor work on a large scale. Attention has therefore in some cases been directed to rendering the protective coverings on armoured cables as good a protection as a good solid system, but with the very important advantage that the work can be carried out in the cable-makers' shops under careful supervision and without any consideration of weather. All armoured cables laid by the power companies operating on the north-east coast now have a layer of a flexible bitumen compound 1/10 in. thick, directly on the lead and served with two specially closely woven bitumen-impregnated tapes. The cable is then served over these tapes with compounded jute yarn to form a bed for the armour, after which the armouring, either of steel tapes or wires previously passed through a bath of waterproof composition, is put on. This armouring is then served with jute yarn, passed through a bath of hot compound, and finally lime washed. The total cost of the specially protected armoured cables when laid is very little more than the cost of plain lead-covered cables laid on the solid system, and with this slight extra expense a much more suitable system is obtained.

The Paper next dealt with jointing, and expressed the author's disapproval, both of the copper sleeve joint and telescope joint for conductors, as apt to pull out after overloading and subsequent cooling, or in the event of subsidence of the ground. The method which he prefers and has patented (Patent No. 15,413, 1909), is to lay strips of flexible copper braid longitudinally along the conductors, to bind them on tightly with copper wire, and to solder the whole together. The flexible braid is compressed tightly into all the interstices of the conductor strand, and a joint of this type left unsoldered required one-third of a ton merely to pull one of the conductors out of the braids. A similar joint left unsoldered was run up gradually to 7,000 amperes per square inch, its temperature rise being at all times lower than that of the conductor. An alternative type of this joint for heavier conductors is to insert a layer of the copper braid over each layer of wire.

For insulating the cable, the author preferred the use of plain linen tape boiled in resin oil just before using, to the employment of tapes previously impregnated at the factory. The insertion of alternate layers of mica between the layers of tape actually gave a lower breakdown pressure than with tape only. With taped joints, after each of the three cores has been taped separately, he finds it preferable not to bind them together with a layer of tape from end to end, but to wrap on this tape in the form of bands at intervals along the cores, and similar bands on the cores themselves, as this leaves spaces between the insulated cores and the lead sleeve, which will be filled with oil subsequently poured in.

In a second type of joint the conductors are separated from one another by an insulating spreader or separator, which may be of ebonite, china, or some similar material. The cores are sometimes taped over with insulating tapes, but with certain precautions this is not necessary and is best avoided.

Joints of either type may be filled either with an insulating oil or a joint-box compound (of a solid or viscous nature). Oil is objected to by many engineers, who fear its being absorbed up the cores of the cables, but the author has not met a case in which a breakdown has occurred from this cause, and with cables impregnated under vacuum, as E.H.T. cables always are, the leakage should in any case be very small. In the second type of joint particularly oil or a viscous compound is preferable to a solid compound, as breakdowns have occurred due to shrinkage of the compound taking place in solidification after the joints have been filled.

It has been proposed by one large firm to exhaust such joints by a vacuum pump previous to running in the oil, and this will no doubt effectually provide perfect insulation for all pressures and also prevent any possibility of leakage up the cable cores. The author showed illustrations of this pump in the lantern. The pump produces a 29-in. vacuum in about half a minute, and before filling with oil this vacuum is maintained for about 30 to 40 minutes, and the oil is then let in.

A joint which the author considers more reliable than either of the two types already discussed is one in which the insulation is provided by loosely fitting tubes, preferably of micanite, which are sprung over the cores, the conductor joint being left bare inside them and the tubes overlapping some distance over the ordinary paper insulation at each end. The tubes, which are split on one side with a lap joint, are finally taped over their whole length, but not over the ends, with two layers of insulating tape to keep them together, and the three tubes are separated by star-shaped china pieces taped down to them, which keep them apart and centre them in the lead sleeve. This lead sleeve is then filled in with the insulating composition, either an oil or a viscous joint-box compound—preferably the latter—which can run into the tubes and all parts of the joint box. When cast-iron joint boxes with wiped glands are used to cover the joint instead of lead sleeves, the author recommends bonding across them, as he considers that sufficiently good contact is not made between the brass sleeve and the cast-iron box through the screw thread.

Another alternative suggested by the author, and used more recently, is a wrought-iron sleeve, as shown in Fig. 7, which is also bonded across.

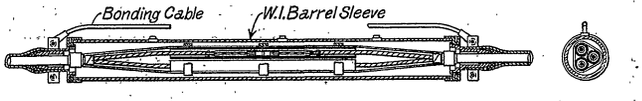

FIG. 7.

Mr. Vernier concluded his Paper with a review of the chief causes of breakdown. Breakdowns due to external damage had been rare in his experience, and had not averaged one case per annum over the past ten years. Other still less frequent cases of breakdowns due to external causes which the author had experienced, were leakage of steam and hot water from steam pipes in the neighbourhood of collieries and shipyards, destruction of the lead sheath by vermin, collapse of a dock retaining wall, and undermining of cables by leakage of water from water mains.

Where bad cases of electrolysis had occurred it had generally been due to excessive leakage from tramway undertakings or from three-wire D.C. networks. When this excessive leakage had been removed and the Board of Trade regulations complied with, electrolysis had been greatly minimised, if not altogether prevented. The author seemed to favour earthing the lead sheath to earth-plates at frequent intervals, but except at these points keeping it insulated from earth.

In mining districts serious trouble arises at times from the pulling out of joints or cable breakdowns due to subsidence of earth movements. These are much more frequent on solid laid cables than on either drawn in or armoured cables, although none of these systems can be said to be altogether free from this trouble. Sometimes the opposite effect, viz., that of compression of joints or of cable bursts, is met with.

When the ground subsides, the lead sheath is able to stretch, but the conductors do not, and the joints pull apart. Laying the cable with slack or snaked in the ground will not prevent this occurring, unless this snaking is done quite loosely in an empty trough. In order to overcome troubles of this sort, the author has designed (Patent 12,146, 1909) an expansion type of joint, which is illustrated in Fig. 8. The conductors are free to slide in a guide tube *a*, and their electrical continuity is maintained by strips of flexible copper braid *b*, which are bound down to them at each side and

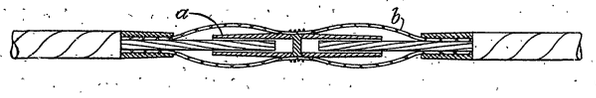

FIG. 8.

Hosted by Google

to the guide tube in the centre in order to maintain the relative positions of the working parts. The insulation of the joint is the one with the micanite tubes already described. Joints of this type have been in use for about eighteen months on several 20,000-volt cables on the power companies' systems in the Newcastle district, and no breakdowns have occurred, although previous to this such breakdowns were very frequent. Joints opened up for inspection have shown movements of over 2 in. to have taken place, in some cases, in a few weeks. The latest joints installed provide for 6 in. movement in all, but joints can be made for much greater limits of movement if required.

These joints may also be employed to take up the expansion due to overload. Assuming a cable is laid in the ground and jointed up originally at a temperature of 60° F. (on cables jointed in winter these figures will be much exceeded), with a safe increase of temperature of 90° F., the conductors will expand 4ft. 6in. in a mile.

In cables laid alongside railway lines the breaking of the lead sheath due to vibration from passing traffic frequently occurs. This source of trouble seems to be confined entirely to cables laid on the solid system, and takes place at the joints of the troughing. The smaller the cable the more severe is the trouble, and even if a small cable and a large one be laid alongside one another in the same trench, the small one will always fail first. Serious cases have actually occurred on lead-covered cables laid within 2 ft. of tramways which were laid on a bed of concrete in the usual manner. The remedy for this trouble is to use only armoured cables laid direct in the ground and at greater depth than usual if within, say, a distance of 4 ft. from rails.

Resonance, fortunately, is not a very common cause of failure under normal conditions of working. Cables have usually a very heavy factor of safety (between 10 and 20, as a rule), and it has been found quite practicable to switch on and off long feeders direct on to the system without using any charging devices. Nothing else has ever been done on the large power companies' systems on the north-east coast, which were first put in operation in 1901, but cable-charging gear was still in use on some other large undertakings as recently as 1904–5 (*Journal* of the Institution of Electrical Engineers, Vol. xxxvi., pp. 85 and 120, 1905).

When pressure surges are the cause of breakdowns of cables or of their joints, it is usually the result of a heavy short circuit, which sets up oscillations in the system, and cables may break down due to a rise of pressure at some point often miles away from the short circuit causing the disturbance. The author added, "There can also be no doubt that the system persists in a condition which may give rise to further pressure rises for some time, as breakdowns often follow upon one another within a few days."

Finally, Mr. Vernier pointed out that it would be an advantage to use a non-metallic waterproof sheath for cables, if one could be obtained, which retained the great advantages of the present lead sheath without its disadvantages.

Our report of the discussion is held over until next week.

"Tantalum" Traction Lamps.—The general manager of a tramway company has written the following letter to Messrs. Siemens Brothers' Dynamo Works, Ltd., Tyssen Street, Dalston:—"Dear Sirs,—In reply to yours *re* the "Tantalum" lamps supplied to us for traction purposes, a sample batch were placed in Car No. — on February 21st, 1910. They have run up to the present 11,670 miles. There has only been one breakage, which took place during the first week the lamps were running. This was a broken globe, not a broken filament. The lamps appear to be still in very good condition, and in view of this test there is no question about them standing up to their work. Would you like us to return these lamps to you, or to leave them in the car and run them to destruction?"

The Metric System.—Our attention has been called by Mr. H. W. Sullivan to the work being done by the Department of Commerce and Labour of the Bureau of Standards, Washington, U.S.A., to popularise the metric system of weights and measures. A pamphlet explaining the system, and a useful book of tables of equivalents in metric and U.S.A. values were published in 1906, and are widely circulated. An effective coloured chart illustrating graphically the relative values is also published. A full-size yard rule is depicted alongside a metre rule, and a three decimeter rule by a foot rule, while the relative values of the weight and volume measures are illustrated by solid cylinders of equal diameter and different heights. This chart is suitable for hanging up in workshops, as it appeals to the artisan, and Mr. Sullivan suggests that the National Physical Laboratory should prepare a similar chart, as, of course, some of the American units are different to the English ones.

ELECTRIC POWER IN THE BIRMINGHAM DRAINAGE SYSTEM

THE Paper by Mr. L. F. Mountfort on "The Electrical Undertaking of the Birmingham, Tame, and Rea District Drainage Board," read recently at Birmingham (see ELECTRICAL ENGINEERING, February 23rd, p. 90), was further discussed by the Manchester Local Section of the Institution of Electrical Engineers on February 28th.

The discussion was opened by Mr. W. CRAMP (Municipal School of Technology), who took up the general question of the electrical driving of centrifugal pumps. The pressure and flow characteristics of a centrifugal pump were of the same general shape as the speed and current characteristics of a continuous-current motor. The exact shape is dependent in the case of the pump by the backward or forward curvature of the blades, and in the motor by the compounding. By suitable choice of these two features a combination can be obtained capable of providing from constant pressure electric supply mains any flow characteristic that we desire. It may be constant head with variable quantity, or constant quantity with variable head. With induction motors there was not the same possibility of adjustment, and hence the author's compromise with radial waves, which rather reduced the efficiency of the combination. He had used the divided end rings which the author objected to on single-phase motor.

Mr. S. J. WATSON (Borough Electrical Engineer, Bury) pointed out one or two inconsistencies in the load factors and statement of output in the Paper, and thought that the costs seemed rather high. He had himself once put down electrical plant at a combined destructor and sewage works. He suggested that a battery might have been employed to level out the peaks of the pumping load. The pump efficiencies were, in his opinion, very good. He did not like the idea of running a private station in parallel with a public supply.

Mr. A. G. COOPER (Borough Electrical Engineer, Colne) spoke of pump efficiencies as high as 75 per cent. At Colne they had separate surface water drains independent of the main sewers. They required about 40 h.p. at their sewage works for a town of 27,000 inhabitants, but there was no pumping to be done.

Mr. A. B. MALLINSON mentioned sewage plants which he had been connected with at Burslem and Huddersfield. At the former, low lift turbine pumps, driven by motors aggregating 160 h.p., and taking power from the town supply over an overhead line, are employed, and at the latter a number of revolving spreaders are driven by 2½-h.p. motors. He asked for some further particulars of the working of the motors and the lightning protection of the line.

Mr. W. B. SHAW asked how the diversity factor had been calculated, and for some further details regarding the drop in the line and the costs. He knew of motors which had refused to start until saw cuts were made in the end rings. With regard to the running in parallel of the station with the town mains, he asked whether any precautions were taken as to the excitation of the generators, as otherwise it might be possible to compel the mains to supply practically all the magnetising current, a state of affairs to which the Corporation Engineer would probably object.

Mr. MOUNTFORT, in his reply, said that the pumps were ordinary centrifugal pumps rather than high-grade turbine pumps, and first cost had been studied rather than very high efficiency. A battery would have been out of the question, as the peaks of the load often lasted for two or three days. With regard to running in parallel with the public supply, he thought that if anything went wrong, it would be the private plant that would suffer the most.

Peebles' Staff Ball.—The staff of Messrs. Bruce Peebles & Co. held a most successful ball recently in the North British Station Hotel, Edinburgh. Mrs. Lee Murray (wife of the general manager of the company), acted as hostess for the Committee, and received the guests. Supper was presided over by Mr. Lee Murray in his own and well-known genial style. The chairman, to use his own expression, "said a few kind words," and the speeches generally were of a high order, and reflected the satisfaction expressed by the shareholders at the annual meeting, which had been held during the day, at the progress made by the company, and with the very excellent work that had been carried out during the year just closed, by every member of the staff.

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the meeting on Thursday:—Associate Members: J. Cowie, C. Davidson, J. Hardey, D. Hume, H. Kirkby, J. Marr, A. Moore, G. Peck, R. Porte, A. Roberts, A. Simpson, F. Symons, R. Whittington, C. Wickham. Associate: S. Stanley. Students: H. Addicott, G. Alvey, R. Andersen, W. Ball, J. Blythe, F. Boa, P. Bogà, W. Bull, E. Cheney, E. Clark, E. Elliman, G. Farrer, E. Fernandez, F. Fletcher, R. Hansford, R. Hargraves, T. Hornblower, M. Ichssan, F. Jackson, E. Johnson, G. Marris, H. Nadejde, A. Newbury, C. Newell, J. Page, D. Payne, R. Rao, W. Richardson, T. Riley, F. Rowcliffe, S. Smith, H. Stevenson, F. Tomlins, T. Turton, J. Warren, A. Woods.

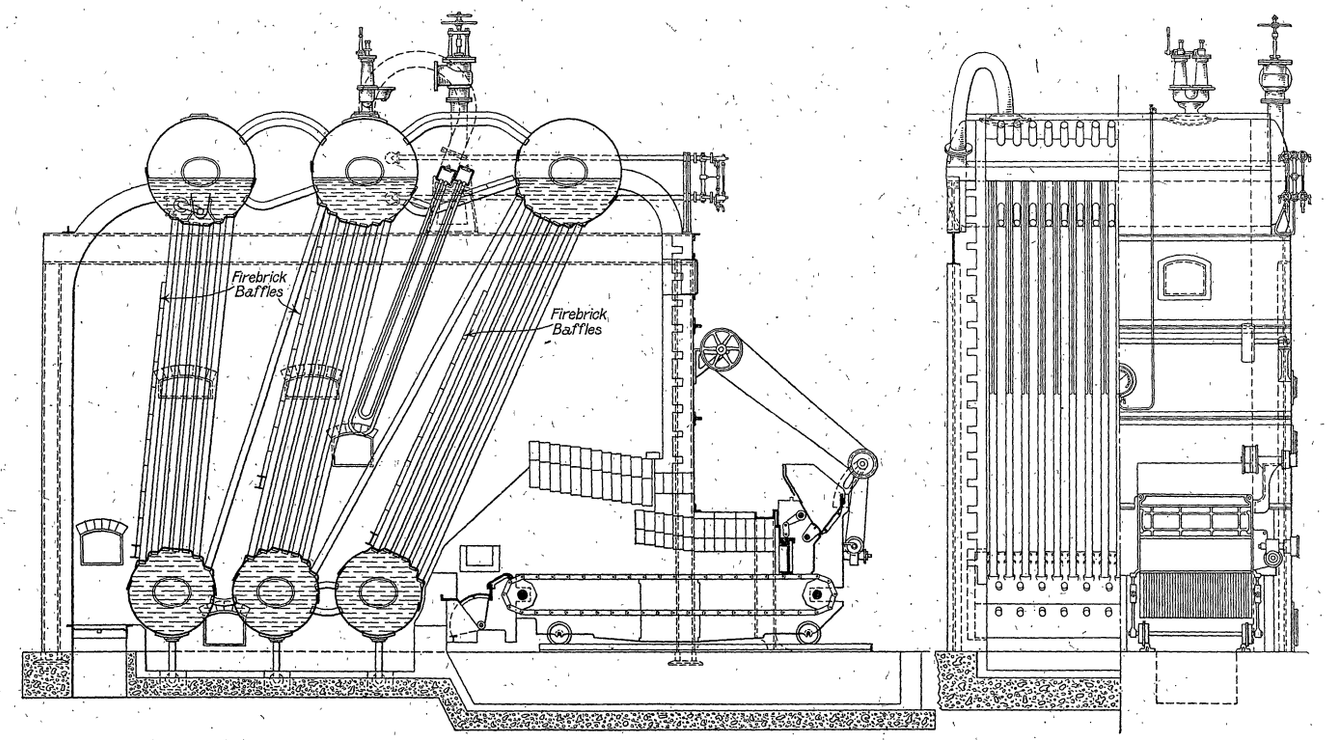
A DISCUSSION ON BOILERS: TWO NEW TYPES DESCRIBED

AT a meeting of the Yorkshire Section of the Institution of Electrical Engineers at Sheffield last week, an informal discussion took place on the selection of the best type of steam boiler. Considerable interest was aroused by the description of two new types of boiler being given for the first time.

The Brightside Boiler.



The first of these is a boiler which is being made by Messrs. Hawksley, Wild & Co., Ltd., at the Brightside Boiler Works, Sheffield. The Brightside water tube boiler is a boiler with tubes nearly vertical. The illustration below shows the general features of a boiler of medium size for evaporating about 10,000 to 22,000 lbs. of steam per hour, from and at 212° F., and for working at 200 lbs. per square inch pressure, but the firm also supplies boilers both of larger and smaller size; similarly, although the chain-grate stoker fitted to the boiler in the illustration is a Bennis, any other make can be fitted. The essential feature of the boiler is the method of pressing the tube plates, which allows straight tubes to be used in parallel rows, the pitch of which is $7\frac{1}{4}$ in. By the use of a special form of die for pressing these tube plates, the surface is at right angles to all the tubes entering. As the tubes are $3\frac{1}{4}$ in. diameter, and the pitch $7\frac{1}{4}$ in., a space of 4 in. is left between, and they can be taken out without drawing through the tube plate, so that no extra head room is necessary as with some types of vertical water-tube boilers. To remove a tube, it is cut off close to the tube plate by the usual method, and passed through the four-inch space to the space over the grate, where it is pushed through the door in the front of the boiler.

By the arrangement of the tubes in banks as shown, the first bank comprises $33\frac{1}{3}$ per cent. of the heating surface of the boiler, and 70 per cent. of the evaporation is performed there. The second bank supplies 36 per cent. of the heating surface and 22 per cent. of the evaporation, while in the third bank only 8 per cent. of the total evaporation takes place. Owing to comparatively low evaporation at the rear end, there is true progressive heating, and the water deposits its scale on the surfaces of these rear tubes. The boiler is illustrated fitted with a large superheater for 200° of superheat.

The Bettington Boiler.

The other new boiler described at the meeting is a water-tube boiler on an entirely new principle, for burning pulverised coal. It is made by Messrs. Fraser & Chalmers, Ltd., of 3 London Wall Buildings, E.C., and Erith, under the Bettington patents. The boiler has vertical tubes in circular headers. A mixture of pulverised coal dust and air is blown in through a vertical inlet, and a mushroom-shaped flame is produced within the closed ring of vertical tubes. A temperature of 3,000° F. or more is attained, and the returning gases always ensure incandescent brickwork around the tuyère so that heat is stored in them, and, after a temporary stop, it is sufficient to restart the fire merely by turning on the fuel supply.

The ash, as it passes through the zone of highest temperature, becomes converted to a liquid spray, and, being unable to adhere to the water-cooled surfaces, it drips down to the ashpit in the form of small globules, which are easily discharged to an ash conveyer or raked out. This liquid spray also incidentally seals up any crevices in the brick lining.

THE BRIGHTSIDE WATER-TUBE BOILER. (HAWKSLEY, WILD & CO., SHEFFIELD.)

The coal is fed into a hopper placed at the side of a combined pulveriser and blower, and the gases on leaving the boiler pass through an air heater, which pre-heats the air before it is drawn into the pulveriser fan and mixed with the coal dust. It is estimated that only about 3 per cent. of the total power developed in the boiler is required for the pulveriser and fan, and by the pre-heating of the air coal containing even up to 15 per cent. of moisture can be disintegrated and burnt.

Boilers of this type have been constructed in sizes from 6,000 to 40,000 lbs. per hour evaporative capacity, and a number of these have been in use in South Africa for some time. In one case, a low-grade coal was used, and a thermal efficiency of only 55 per cent. had been attained previously with a hand-fired water-tube boiler, even after screening and picking, while with the same coal, but without screening, an efficiency of over 80 per cent. was attained with the Bettington boiler. A boiler has been erected for demonstration purposes at Messrs. Fraser & Chalmers' works at Erith, and the erection of another is just being completed at a municipal electricity works. The boiler at Messrs. Fraser & Chalmers' works has been running regularly for over a year. It has 2,606 sq. ft. total heating surface with a single 14 in. tuyère fed with pulverised fuel and pre-heated

Hosted by Google

air by the pulverising fan. Its calculated capacity was 10,000 lbs. of steam per hour, but we understand that it has been found to evaporate 12,000 lbs. without forcing, and has worked up to 22,000 lbs. without difficulty and with a correspondingly good efficiency.

Water-tube v. Lancashire.

The discussion at Sheffield, in the course of which these boilers were introduced, was opened by Mr. A. B. MOUNTAIN (Borough Electrical Engineer, Huddersfield), who briefly described and compared the boilers most commonly in use. He pointed out that the Lancashire and Yorkshire boilers both have the advantages of a large reserve of water and extreme simplicity of construction, but suffer from the impossibility of having a large grate area, and have a low evaporation per square yard of floor space. Another defect is the air leakage through the brickwork due to the constant expansion and contraction, and the liability to leakage from the down tube at the back of the boiler to the side flues, enabling the gases to pass straight from the back to the main flue. Comparing the Yorkshire with the Lancashire boiler, the furnace tubes of the former are gradually enlarged to the back of the boiler, and it is estimated that a 24 ft. Yorkshire boiler will do the same duty as a 30 ft. Lancashire.

Dealing next with the Babcock & Wilcox boiler, after describing it generally and appreciatively, Mr. Mountain suggested that, as the steam generated in all tubes has to pass up the front headers to the top drums under conditions of forcing, priming might result if superheaters were not used. The principle of the Stirling boiler was also explained and favourably commented on, and the question was asked whether the bent tubes implied any danger due to the difficulty of cleaning. The arrangement of the Woodeson or Clark-Chapman boiler, one of the latest developments in the vertical straight tube type, was also reviewed, and Mr. Mountain asked if any trouble had arisen from the flat surface into which the tubes are expanded, and if there were any difficulty in getting the dirt from among the tubes. He pointed out, however, that the ease with which the tubes can be cleaned and inspected is a strong point, but the fact that new tubes have to be put in through the manholes in the top drum, while very simple, necessitates a specially high building to allow the tubes, which are 14 ft. 6 in. long, to be withdrawn or replaced.

Mr. Mountain then gave brief descriptions of the two new boilers referred to at the commencement of this article.

On the question of maintenance and repairs, Mr. Mountain said that although there is not much difference in the maintenance costs for the various types of boilers, the arrangements for cleaning the water-tube boilers are much in advance of the Lancashire type, and he thought that the application of the vacuum cleaner to all boiler houses would no doubt become general and save much most unpleasant labour as well as improving the efficiency of the plant. He also mentioned that the first-class makers of fittings are now generally using steel for the bodies of all boiler mountings, and characterised cast iron fittings as not reliable.

The remainder of Mr. Mountain's remarks were devoted to a comparison of the cost of installation and efficiency of various boilers. Assuming that an evaporative capacity of 12,000 to 15,000 lbs. per hour was desired, he estimated the approximate cost as follows, including the cost of buildings, chimney, flues, economisers, stokers and fans for the water-tube boilers, but not including the cost of land:—8 Lancashire boilers, £16,750; 8 Yorkshire boilers, £15,500; 5 Babcock boilers, £15,000; 4 Woodeson boilers, £14,000; 4 Stirling boilers, £13,500. The efficiencies he assumed to be:—Lancashire, 65 per cent.; Yorkshire, 65 per cent.; Babcock, 70 per cent.; Stirling, 72½ per cent.; Woodeson, 72½ per cent.; and, taking the boiler to be evaporating at the rate of 100,000 lbs. of water per hour and working, say, 300 days of 18 hours, that the fuel to be worth 10s. per ton, he estimated that the annual saving due to the use of water-tube boilers over Lancashire or Yorkshire boilers would be from £750 to £1,125 per annum, in addition to the saving of capital and reduced cost of labour due to the fact that a smaller number of boilers would be in use.

Mr. HARTNELL mentioned the uniformity for all types of boilers of the curve connecting coal consumption per unit of heat surface with evaporation, and also spoke of the advantage of large grate areas, and boilers of large size.

Mr. CASMEY (Yorkshire Boiler Co.) explained at length the useful features he claimed for the Yorkshire boiler.

Mr. ATKINSON (Clarke, Chapman & Co., Ltd.), replying to Mr. Mountain's criticism, said that the connecting tubes between the drums of the Woodeson boiler were kept as straight as possible, and that the dirt was easily removed from between the tubes. He said that an allowance of 10 ft. head room above the upper tube plate was sufficient.

Mr. PIGGOTT (Babcock & Wilcox, Ltd.) said that the priming which Mr. Mountain feared in the Babcock boiler did not occur.

Mr. MCKAY (Stirling Boiler Co., Ltd.) explained that one of the objects in boiler design was to obtain the cheapest boiler per square foot of heating surface. Referring to the question of priming, he said that five years ago his company had accidentally discovered a method of curing priming, by one of their men having omitted to clean the circulating tubes between the two bottom drums. The improvement in this respect was at once manifest, and now only two tubes connect the two bottom drums to steady the water pressure between the rear and front tubes. The size of the drums of the Stirling Boiler Company had been increased from 3 ft. to 4 ft. in diameter. He had investigated straight tubes, but had come to the conclusion that the boiler with straight tubes having the same number of drums top and bottom did not have sufficient circulation. Moreover, each tube must take up its own expansion and contraction without creeping at the tube plates or producing leakage. This, he claimed, could only be accomplished by having bent tubes.

Mr. NOBEL (Hawksley, Wild & Co., Ltd.) explained the construction of the Brightside boiler (see page 138), and expressed the opinion that while the Yorkshire boiler might have advantages over the Lancashire boiler, yet it could not compare with any of the water-tube boilers shown.

Mr. V. BETTINGTON, who with his brother had invented the coal-dust boiler already described, explained its action, and answered several questions.

Mr. YERBURY (Electrical Engineer to Sheffield Corporation Tramways) pointed out that if Mr. Mountain had included the value of land in comparison with capital costs, the water-tube boiler would have shown to still better advantage.

A speaker favoured the marine tube boiler, both because of its high evaporative efficiency, and the small amount of floor space it took up, but a subsequent speaker pointed to the difficulty of obtaining superheat with a boiler of this class.

PARLIAMENTARY INTELLIGENCE

A House of Commons Committee last week dealt with the Bill of the Metropolitan District Railway Co., which proposes to form a Joint Committee to acquire the Lot's Road Power Station now owned by the Underground Electric Railways Company of London. As originally drafted, the Bill contained a clause empowering the Joint Committee to supply electrical energy to all the railway companies in London, and also general powers to supply electricity in bulk. There was considerable opposition to the latter proposal. Many of the London Electric Supply Companies petitioned against the Bill, but eventually they were all satisfied by a modification in the clause which struck out bulk supply, except the Metropolitan Electric Supply Company, who wished to prevent the Joint Committee from supplying the London & North Western Railway Company. The Bill has also been modified in a manner to prevent the Joint Committee from tendering for supplying the London, Brighton & South Coast Railway Co. The Metropolitan Electric Supply Co. withdrew its opposition to the Bill in the House of Commons, reserving the right to appear against it in the House of Lords, and eventually the preamble of the Bill was found proved, the Joint Committee being granted authority to supply electrical energy to the Metropolitan, London & South Western, Whitechapel & Bow, Great Northern & City, Central London, City & South London, London & North Western, North London, London, Tilbury & Southend, Wimbledon & Sutton, Great Western and Metropolitan Railways, and any other railway or tramway company with which the Metropolitan District and London Electric Railway Companies have through traffic or physical connections. It was further made clear in the Bill that the Joint Committee only has power to supply these railway and tramway companies, and is not able to take over any of their statutory powers. The Joint Committee will consist of three members each of the District and London Railway Companies, the lease being for 999 years.

The Bill of the London Electric Railway Co. was also under consideration by a House of Commons Committee last week. It proposes to construct a short loop line linking up the Trafalgar Square station of the Bakerloo Railway and the Charing Cross station of the District Railway Co., and also about half a mile of line joining up the Edgware Road station of the Bakerloo Company with the Paddington station of the Great Western Railway Co. To the former proposal there was no opposition, but to the latter there was opposition from the District Railway Co. The Great Western Railway Co. is financially interested in this extension. The preamble of the Bill was found proved.

The Halifax Corporation Bill was before the Standing Orders Committee in the House of Lords on Thursday, but was allowed to proceed on condition that four lengths of tramway, in respect of which the consents of the road authorities had not been secured, were struck out.

Electric Driving at a London Printing Office.—In the article on the *Illustrated London News* and *Sketch* printing office, which appeared in our issue of March 2nd, it should have been stated that Electromotors, Ltd., of Openshaw, Manchester, were the Main Contractors for the electric power equipment.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published March 9th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

4,299/10. **Lampholders for Trough Reflectors.** J. H. CUNNINGTON (London). A twin lampholder for taking two lamps end to end in a trough reflector consists of a cylindrical body with ordinary holders at each end, and a small clear space between for wiring. Five figures.

12,889/10. **Cooling of Commutators.** BRUSH ELECTRICAL ENGINEERING CO., LTD., and A. W. JONES. Commutators or slip-rings are enveloped in a stationary sleeve of insulating material cut away at convenient points to admit the brushes. Air circulates through the annular passage left between the sleeve and the commutator surface, special inlet and outlet openings being provided. Six figures.

16,342/10. **Frequency Meter.** SIEMENS & HALSKE A.-G. An instrument for indicating and recording frequency consists of a voltmeter arranged in parallel with an inductance, with a condenser in series with both. The closed iron circuit of the inductance is saturated so that the resonance point of the measuring circuit is displaced with any alteration of current, and the circuit is tuned so that the whole range of the instrument lies outside the resonance point. The use of a high saturated transformer with large leakage, and also of a second voltmeter in opposition, to eliminate the effect of variations in the pressure, are also covered by this patent. Five figures.

16,419/10. **Train Telephony.** H. VON KRAMER (Erdington). This patent covers certain details in the system of train telephony by magnetic induction between coils on the carriages and conductors along the line, which is now being tried on some railways. Two coils are employed, one for transmission, and one for reception. The active part of each coil is arranged beneath the carriage parallel to the line, while the rest of the coil extending over the roof is enclosed in a tube of brass or other non-magnetic metal. Eight figures.

26,120/10. **Heating Apparatus.** BRITISH THOMSON-HOUSTON CO. *(General Electric Co., U.S.A.).* A flat heating unit for hot-plates and other electric heating apparatus is constructed by covering a length of the insulated resistance conductor with a metal tape or a thin metal sheath deposited on the insulation. The conductor is then wound into a close helix and electroplated until the whole becomes as rigid as a solid disc of metal. This results in a heating unit in which the conductor is in close contact with the metal to be heated, and is well protected. Four figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: RADFORD, MUNTON, and JONES [Coil-winding machine] 4,129/10.

Dynamos, Motors, and Transformers: SIEMENS BROS. DYNAMO WORKS *(Siemens-Schuckertwerke Ges.)* [Rotary field transformers] 21,583/10.

Electric Ignition: COMPAGNIE POUR LA FABRICATION DES COMPTEURS A GAZ [Automatic ignition of gas burners] 11,722/10; SOC. D'ELECTRICITE NILMELIOR [Make and break device] 20,863/10.

Electrometallurgy and Electrochemistry: URBAIN, FEIGE and SEAL [Sterilising liquids by electric arc] 4,795/10; CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE GES. [Manufacture of persulphuric acid] 23,548/10.

Incandescent Lamps: ELDRED [Leading-in wires] 4,467/10; CERVENKA [Manufacture of filaments] 8,341/10; BRITISH THOMSON-HOUSTON CO. *(General Electric Co., U.S.A.)* [Leading-in wires] 13,295/10; SIEMENS & HALSKE A.-G. [Manufacture of metal filament lamps] 19,077/10.

Instruments and Meters: STROMBERG and WILLIS [Meters] 4,273/10; CAMBRIDGE SCIENTIFIC INSTRUMENT CO. and DARWIN [Thermoelectric circuits] 24,668/10.

Storage Batteries: HARDY and HUNGERBÜHLER, 4,320/10.

Switchgear, Fuses, and Fittings: LEBEDENKO [Cable sockets] 30,491/09; HINSKY [Insulated wiring conduit] 5,048/10; MORRIS and LISTER [Switches] 5,221/10; BRIDGE [Automatic make and break device] 6,719/10; COLLINS [Lamp-holders] 8,913/10; ADAMS MANUFACTURING CO. *(Cutler Hammer Manufacturing Co.)* [Motor starters] 9,101/10 and 17,340/10; LOBEL and BRITISH EVER-READY ELECTRICAL CO. [Lamp-holders and fittings] 11,051/10.

Telephony and Telegraphy: COOPER and BRITISH INSULATED AND HELSBY CABLES, LTD. [Automatic cradle switches for telephones] 7,361/10; BALDWIN [Sound-reproducing device of telephone-receiver type] 10,774/10; DYMOND *(Ges. für Drahtlose Telegraphie)* [Production of slightly damped oscillations by shock-excitation method] 18,545/10; LAMKIN and PACE [Sound-magnifying device for telephones] 20,399/10; GOLDTHORP [Wireless receiving apparatus] 25,280/10; AMERICAN AUTOMATIC TELEPHONE CO. and GOODRUM [Automatic telephone exchanges] 28,057/10; DICKER *(Automatic Electric Co.)* [Impulse-transmitting devices for automatic telephone systems] 29,654/10.

Miscellaneous: DE FERRANTI [Thrust bearings and shaft packings] 5,035/10 and 5,169/10; HIRST [Coal-cutters] 10,358/10; MUREX MAGNETIC CO. and LOCKWOOD [Separation of ores] 13,009/10; MIRAM and SEIDEL [Electromagnetic clutches] 19,952/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: SIRE [Machines] 2,903/11.

Electric Ignition: MAZELLIER [Sparking plug] 3,859/11; UNION-WERKE MEA GES. ELEKTROTECHNISCHE FABRIK EISENWERK [Magneto apparatus] 4,085/11.

Electrometallurgy: MELLEN & MELLEN [Manufacture of aluminium and copper alloys] 3,361/11.

Incandescent Lamps: ROYER, 3,541/11; WEISSMANN [Filaments] 3,950/11.

Instruments and Meters: WEINTRAUB [Electrolytic meters] 3,648–9/11.

Telephony: CAMPBELL and SHAW [Loaded phantom circuits] 3,422/11; SHAW [Loaded phantom circuits] 3,423/11.

Miscellaneous: MIRAM and SEIDEL [Electromagnetic clutches] 19,786/10.

The following amended Specifications can now be obtained.

STEINWEG [Soldering aluminium] 6,138/09; SCOTT [Disc coal-cutters] 4,357/10.

Opposition to Grant of Patents

25,231–2/07. **Exhaust Steam Accumulators.** JAMES HOWDEN & CO., LTD., and W. H. OWEN. The Law Officer has confirmed, on appeal, the decision of the Comptroller to grant these two patents. The first covers the use of a minimum-pressure boiler intermediate between the high-pressure engine and the low-pressure turbine, which acts both as a steam accumulator and as a source of steam when the supply of exhaust steam fails. The second patent covers the use of a superheater between the steam accumulator and the turbine.

21,008/09. **Arc Lamp.** L. D. CIBIE. The grant of this patent has been allowed in spite of opposition, but the Comptroller's decision requires an amendment to the specification. This was abstracted in ELECTRICAL ENGINEERING, Oct. 13th, 1910, p. 648, and describes a lamp in which one carbon is guided in a socket having a spherical bearing and rests on a stop attached to this socket.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

7,011 of March 17th, 1897. **Time Switch.** J. GUNNING. This patent covers a time switch for extinguishing lamps at a predetermined time, and consisting of a clockwork mechanism driving a dial on which is an adjustable arm. The latter is caused to open a switch when the dial has carried it round so as to engage with the switch.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: BRITISH THOMSON-HOUSTON CO. *(General Electric Co., U.S.A.)* [Vapour rectifiers] 24,025/05.

Distribution Systems, &c.: E. T. RUTHVEN-MURRAY [Supports for cables laid in troughs on solid system] 25,284/03; A. M. TAYLOR [Load-equalising plant] 25,620/04.

Electrometallurgy, &c.: COMPAGNIE FRANCAISE DE L'OZONE [Ozone apparatus for treatment of water] 12,061/04; J. HARGREAVES [Electrolytic apparatus] 25,331/04.

Instruments, &c.: BRITISH THOMSON-HOUSTON CO. and F. HOLDEN [Prepayment meters] 25,658/03.

Switchgear, &c.: C. SMART [Automatic switch for substituting incandescent lamps for arc lamps, &c.] 25,235/03; ZAPF [Lightning arresters] 25,657/03; BRITISH THOMSON-HOUSTON CO. and J. M. WALLACE [Oil switches] 23,894/05; F. E. IMESON [Contact fingers for controllers] 24,183/05.

Telephony, &c.: G. MAGINI [Use of coherers in line telegraphy] 25,191/04.

Miscellaneous: SALWÉN [Magnetic separators] 23,823/01; SIEMENS & HALSKE A.-G. [Tantalum electrodes for vacuum tubes] 25,282/04; P. C. HEWITT [Use of vapour lamp to intensify current variations] 25,406/04; J. T. SCHAAFF [Electrically-actuated typewriters, &c.] 25,431–2/04.

FIRE EXTINGUISHER

An arc and fire extinguisher, especially designed for use in electricity works, mines, factories, and motor garages, has been introduced by Simplex Conduits, Ltd. (113 Charing Cross Road, London, W.C.). This extinguisher is claimed to be equally as efficient as any other at present on the market, with the addition that it will extinguish an electric arc and put out burning petrol. The fluid used is a non-conductor of electricity, and can therefore be used on burning cables, &c., which are still alive, without fear of assisting the formation or persistence of an arc. It can also be directed on to machinery in motion to extinguish a temporary short-circuit. The device consists of a cylindrical vessel full of a patent liquid which is forced out by means of compressed CO_2. The gas is contained in a small cylinder attached to the main cylinder; the jet is said to carry 40 ft. Tests made at the Birmingham Municipal Technical School have proved that the liquid does not damage the insulation of cables, and that arcs of several hundred amperes were immediately extinguished by the jet, whether between carbon electrodes or insulated cables.

Arc and Fire Extinguisher.

NEW HOLOPHANE SHADES

Through the courtesy of Messrs. Drake & Gorham we are able to illustrate a pair of new designs of holophane reflectors, specially intended for household use. While retaining the reflecting features of the well-known stiletto pattern of shade in the vertical flutings of the upper part, they are, as can be seen in the illustrations, provided with a more ornamental lower border, giving very much the effect of a bead fringe, but with very much greater efficiency of distribution. In appearance they are an advance on any holophane ware that has been produced.

New Patterns of Holophane Reflectors.
(*Messrs. Drake & Gorham.*)

AUTOMATIC TIME BALL

An interesting time-indicating equipment has been installed at the offices of Messrs. S. H. Benson, Ltd., the well-known advertising contractors, of Kingsway Hall, Kingsway, London. A time ball of 4 ft. diameter has been mounted on the summit of the dome of the building, and is dropped precisely at each hour by a current impulse direct from Greenwich Observatory. Unlike other time balls which only work once a day, and require to be set up by hand daily before their fall, this one is wound up automatically shortly before each hour of daylight by a ¼-h.p. motor through a double-worm reduction gear, with a ratio of one to 10,000. Messrs. Benson's have their offices equipped with the "Synchronome" system of electric clocks, and the installation has now the additional duty of switching on the motor to raise the time ball at ten minutes before each hour. The ball is lifted to the top of the mast in about five minutes, and a clutch falls out of action automatically, leaving the ball held up on a hair trigger ready for release by the Greenwich time signal, which is transmitted over the lines of the Standard Time Co., Ltd. The architects specified that there should be no shock occasioned by the fall, and this has been overcome by a system of counterbalancing. Just before the ball reaches the bottom, the switches are replaced, leaving the motor ready to raise the ball before the next hour. The equipment was designed by Mr. Hope-Jones, and carried out by the Synchronome Co. (32-34 Clerkenwell Road, London, E.C.).

HOLBORN STREET LIGHTING

When the report of the Works Committee of the Holborn Borough Council on the question of public lighting came before the Council at the meeting on Wednesday last week, the action of the Committee in recommending that further tenders be invited from both the Gas Light & Coke Co. and the Metropolitan Electricity Supply Co. was severely criticised. A councillor complained that the statements made at a previous meeting as to the reversion of several Boroughs to gas (Electrical Engineering, February 16th, p. 81) were wholly inaccurate, and Councillor Angel admitted that they were. He said that this list was not prepared by the Borough Surveyor, as had been suggested, but he believed that it originated from the Gas Light & Coke Co. An amendment that the Council should accept the tender of the Metropolitan Electric Supply Co., which was lower than that of the Gas Co., was rejected by the Mayor as being out of order, and it was argued that the competing undertakings had not had an opportunity to tender on equal grounds to a specified schedule. Alderman Green moved an amendment that the 5-year contract proposed by the Works Committee should be altered to a 10 years contract, with the option on the part of the Council of terminating it at 5, 6, 7, 8 or 9 years on payment of a sum to be specified in the tender. He thought it unreasonable to ask the Metropolitan Electric Supply Co. to tender for a shorter period in view of the capital costs which they would have to allow for.

Councillor Clarke, Chairman of the Works Committee, said everyone had warned him against a 10-years contract, as something might happen in the meantime which would considerably reduce the cost of lighting. It had been agreed between the Borough Surveyor and the Metropolitan Electric Supply Co. that in the event of electric lighting being adopted only, between four and five miles of road in back streets and mews would have to be disturbed, and that there would, therefore, be no inconvenience to the public.

Eventually the Committee's recommendation was accepted as amended by Alderman Green, and the Gas Light & Coke Co. and the Metropolitan Electric Supply Co. will therefore be asked to submit fresh tenders according to the schedule prepared by the sub-committee (see Electrical Engineering, March 2nd, p. 110), and a new specification.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

SEARCHLIGHTS.—An illustrated brochure from the Allgemeine Elektricitäts-Gesellschaft of Berlin contains full descriptions of this firm's various patterns of searchlights with Zeiss mirrors and other novel features. Different methods of electrical and mechanical operation are described, and the dimensions and weights of the various types are listed. The forty-four figures include some night photographs and illustrations of special equipments for naval and military purposes.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

COUNTRY HOUSE LIGHTING.—A booklet from the Crypto Electrical Co. (149-159 Bermondsey Street, S.E.) contains particulars of a compact generating set of small size, consisting of one of the firm's continuous-current generators, direct-coupled to a vertical single-cylinder petrol or paraffin engine. The sets are made from 2 to 20 h.p. A series of sets with horizontal engines and belt-driven generators is also included, and the list deals with suitable batteries and switchgear.

We have received an illustrated prospectus of the Working Men's College (Incorporated), Melbourne, for 1911. The college embraces a large number of departments, and courses in electrical engineering are included in the engineering section. There is a special telephone artificer's course, and a separate department is devoted to mining work.

Hosted by Google

LOCAL NOTES

Bournemouth: *Tramway Reconstruction.*—The General Manager of the tramways hopes to have the change-over from conduit to the overhead system in the centre of the town completed in time for the Easter traffic.

Glasgow: *Tramway Assessment.*—The Tramways Committee's recommendation that the Corporation should appeal against the assessment of the tramways, which is at present based upon the full valuation instead of one-quarter, as is claimed should be the case, has been passed by the Corporation. The Tramways Committee have paid on the present basis for the past two years, but under protest, and now desire to have the point settled.

Grimsby: *The Proposed Tramway Purchase.*—A sub-committee of the Tramways Committee, after having considered the matter carefully, have recommended that the tramways undertaking should not be purchased by the Corporation at the present time.

India: *Calcutta: Street Lighting.*—Last year the Calcutta Corporation carried out a series of tests of various arc lamps over a period of four months, and Mr. Reynolds, who was appointed for the purpose, recommends the adoption of the "Excello" arc lamps, which he states are more expensive in capital cost, but are more economical in working. It is, therefore, proposed to install 140 arc lamps to displace 209 gas lamps. It is recommended that they should be placed not more than 75 yards apart. The working expenses per lamp per annum are put at £2 18s. 8d.

London: *Marylebone: Sales Department.*—Dealing with the district auditor's report for the year to March 31st, 1910, which is mainly confined to the working of the Sales Department, the Finance Committee point out that no attempt is made in the accounts of this department to credit the value of the sale of current arising from the profits of the department, nor to debit it with any theoretical apportionment of the various management and establishment charges, salaries, &c., which it would be necessary to readjust and alter from time to time. It is impressed upon the Council that the Sales Department does not exist as a separate entity. The committee recommend the continuance of the present method of keeping the accounts, namely, to show as nearly as possible the exact cost of the department, *i.e.*, the additional cost due to its setting up, and to set against this the income derived from the gross profit of the sale of apparatus, &c., effected by it. At the same time, it is proposed to submit at the close of each financial year a combined report of the Finance and Electric Supply Committee with a view to stating as far as possible the exact financial effect of carrying on the sales branch.

Nottingham: *Charges for Electricity.*—At a meeting of the Notts and Derbyshire Traders' Association last week discussion took place upon the high charges for electricity supply in Nottingham. It was alleged that the charges to consumers are on the average considerably more than in other towns, and that the generating costs exceed by 33 per cent. the average cost in eighteen towns of similar output. A resolution calling for an examination of the cost of the department with a view to a reduction in charges was carried.

Sunderland: *Street Lighting.*—The Electricity and Lighting Committee recommend that 47 gas lamps upon the route of electricity mains be converted to electricity.

Torquay: *Tramway Arbitration Costs.*—The Electric Lighting Committee have decided to make a grant of £500 towards the costs of the tramway arbitration, in spite of opposition from several members, who complained that the electric light consumers should not be deprived of this sum of money.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Barnstaple.—A Local Government Board inquiry was held last week into an application for a loan of £1,970 for electric lighting extensions.

Glasgow.—A twelve months' supply of cables and meters is required by the Electricity Department. (See an advertisement on another page.)

Handsworth.—The Electricity Committee invite tenders by March 28th for a 600-kw. mixed-pressure D.C. generator, jet condensing plant, motor-driven pumps, natural draught cooling tower, pipes, valves, &c. Particulars from the Town Clerk.

Hull.—The Electricity Committee invite tenders by March 28th for two 2,000-kw. turbo-alternators. Particulars from the City Electrical Engineer.

South Africa.—The Krugersdorp Municipality is negotiating for a supply of energy from the Victoria Falls and Transvaal Power Co.

Stoke-on-Trent.—At a special meeting of the Council on Thursday it was decided to proceed with Mr. Yeamian's scheme for the construction of a new power station, and the generation of high-tension three-phase current, at an estimated expenditure of £60,000. The new power station will be erected on land adjoining the present Hanley works. The committee's recommendation to proceed with the scheme was carried by 40 votes to 22.

Wednesbury.—Mains are to be extended to the Newtown district at an estimated cost of £480.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

H.M. Commissioners of Works invite tenders for electric bell-hangers' work in their buildings. (See an advertisement on another page.)

King Edward Memorial Hospital at Ealing.

PROVINCES.

Accrington.—Elementary school at Clayton-le-Moors.

Birmingham.—Warehouse in Southern Street for Messrs. A. Brown & Co. Architects, J. & L. Lea & Sons, 19 Cannon Street.

Bradford.—Workhouse at Daisy Hill.

Bridgewater.—Quarter House and Police Station in Northgate.

Edinburgh.—Foundries in London Road. A Hunter Crawford, 10 Randolph Place.

Handsworth.—Additions to Rookery Road Junior School. Architects, Messrs. Wood & Kendrick, High Street, West Bromwich.

Ilkeston.—New school in Cotmanhay district.

Keighley.—Plans are being prepared for new swimming baths.

Perth.—Alterations and extensions at the County of Perth Infirmary. Architect, James Miller, 15 Blythswood Square, Glasgow.

Southampton.—School buildings in French Street. Borough Engineer.

Stockport.—Hotel in Northgate Street.

MISCELLANEOUS

Edinburgh.—Tenders are invited by March 27th for a year's supply of bitumen, arc lamp globes, pavement boxes, and conduits. Particulars from the City Electrical Engineer.

Govan.—Tenders are invited by March 28th for a twelve months' supply of stores, including arc lamp carbons, joint boxes, cable accessories, house services, meters, fuse boxes, &c. Particulars from the Borough Electrical Engineer. (See an advertisement on another page.)

London: *County Council.*—Tenders are invited by March 28th for four electric watering cars with rail grinding apparatus, and four electrical equipments for the watering cars for operation upon both the conduit and overhead systems of traction. Particulars from the Chief Officer of Tramways.

Wallasey.—The Electricity Committee invite tenders by April 13th for mains, cable and junction boxes, switches and cut-outs, &c. Particulars from the Borough Electrical Engineer.

TENDERS RECEIVED AND ACCEPTED

Birmingham.—Considerable comment has been going on in the daily papers with regard to the decision of the Birmingham Tramways Committee to pass an order for German tramway rails of a value of £11,000. The saving to the committee by the acceptance of the German rails is £900. A condition of the contract is that the standard rate of wages in the district in which the rails are manufactured is to be paid.

Hosted by Google

Burnley.—The tender of the British Westinghouse Co. for a steam turbine driving two 250-kw. generators has been accepted.

Canada.—The Brush Electrical Engineering Co., Ltd., through their agents, the Canada Ford Co., of Montreal, has received the contract for the supply of six cars (four single truck single deck, and two double truck single deck), for the municipal tramway system at Regina. The cars will be fitted for the overhead trolley system, and will have standard D.C. equipments.

Edinburgh.—Tenders for the cooling towers at Dewar Place have been received, and are now in the hands of the consulting engineer, Sir Alexander Kennedy, for report.

Leith.—The Dock Commission have accepted the tender of the Chloride Electrical Storage Co., Ltd., at £2,032, for extensions to the electrical plant.

Tenders have been received for cables from all the principal British makers and one German firm. In the case of the British firms the tenders were all about £4,000, whilst the German tender was slightly higher. The latter was subsequently asked for a definite tender, and, knowing that they were in competition with British firms, they reduced their prices by about 16 per cent. The Works Committee recommend that a British tender should be accepted, but the matter has been referred back to the sub-committee.

Loughborough.—The tender of the Brush Electrical Engineering Co., Ltd., for two 350-kw. turbo-alternators at £1,368, has been accepted. The full list of tenders was given in our last issue. The Brush Co. are also to supply a commutator grinder.

Sunderland.—Messrs. Lucy & Co. have been given an order for street lighting fittings.

Whitehaven.—Messrs. Chamberlain & Hookham, Ltd., have received a contract for prepayment meters.

The order for 3-ampere meters for the coming year has been placed with the Bastian Meter Co., Ltd.

APPOINTMENTS AND PERSONAL NOTES

Professor J. A. Ewing, F.R.S., Director of Naval Education, was married at Christ Church, Westminster, on Thursday, to Miss Ellen Hopkinson, daughter of the late Dr. John Hopkinson, F.R.S.

Mr. T. Petersen has been appointed acting secretary to Messrs. Callender's Cable & Construction Co., Ltd., to fill for the present the vacancy occasioned by the death of Mr. H. E. Harrison.

Mr. J. W. Dugdale has been presented with a fumed oak smoking cabinet and a silver-mounted pipe by the tramway employees at Ashton-under-Lyne, on the occasion of his appointment as tramways manager at Oldham.

Electricians, fitters, turners, &c., are required in the Mechanical Transport Section of the Army Service Corps. (See an advertisement on another page.)

The Bristol Corporation Electricity Department have a vacancy for an improver. (See an advertisement on another page.)

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5, Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £57 to £57 10s. per ton (last week, £57 to £57 5s.).

Dissolution of Partnership.—J. Petkin and H. B. White, carrying on business as J. Petkin & Co., electrical engineers, Red Lion Street, Clerkenwell, has been dissolved.

D. L. Selby Bigge and R. G. Bell, trading as D. Selby Bigge & Co., electrical engineers and contractors, Newcastle-on-Tyne, have dissolved partnership. Debts by D. L. Selby Bigge.

Duralumin.—The Electric and Ordnance Accessories Co., Ltd. (Cheston Road, Aston, Birmingham), inform us that they have appointed Mr. A. W. Wingate (Gisburn, Clitheroe) as sole agent for the sale of "Duralumin" in Lancashire, Yorkshire, Westmorland, and Cumberland. He is prepared to give advice as to the best method of employing the new alloy, which the company are now prepared to supply in various forms.

Plant for Sale.—The Edinburgh Electricity Department have for sale two 100-h.p. Willans-Siemens 250-volt D.C. generating sets, and three 350-h.p. 500-volt D.C. sets. Offers to the Town Clerk by March 25th.

Felten & Guilleaume Carlswerk Aktiengesellschaft.—Communications should now be addressed to the above name instead of to the Felten & Guilleaume-Lahmeyerwerke Aktiengesellschaft, at Mülheim-on-Rhine, Germany.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

British Insulated & Helsby Cables, Ltd.—The net profit for 1910 was £72,320, and after declaring a dividend of 10 per cent. for the year, a sum of £42,320 is carried forward. The directors report that the business during the last year has shown satisfactory growth, largely due to orders obtained through the foreign agencies and connections.

Oxford Electric Co., Ltd.—At the annual meeting last week Sir Henry Mance, who presided, said he agreed with the Tramways Company in shrinking from incurring the heavy expense of installing the conduit system. Whilst there might be objections to the use of overhead trolley system, he thought it was not impossible to design a standard which should be graceful, and to which even the most fastidious could not object. The only alternative to the overhead trolley system was to adopt battery tramcars, which, while more expensive to run, cost considerably less in capital expenditure. He was surprised that this system, which was so popular in America, should be regarded with such disfavour in this country.

W. T. Henley's Telegraph Works Co.—At the annual meeting last week, Mr. George Sutton, the managing director, said whilst the home trade during the past year had been satisfactory, the greatest expansion had been in foreign trade. They had done the largest business on the telegraph side since they began making cables twenty years ago.

Brompton & Kensington Electricity Supply Co.—The net profit for 1910 was £27,583, after meeting interim dividends. A final dividend on the ordinary shares, making 10 per cent. for the year, is recommended, carrying forward £7,443.

South London Electric Supply Corporation.—The net profit for 1910 was £14,002, and a dividend at the rate of 5 per cent. per annum is declared on the ordinary shares, carrying forward £1,002.

Vickers, Sons & Maxim.—A final dividend of 5s. per share, making 10 per cent. for the year, is recommended for 1910, carrying forward £103,970.

South London Electric Supply Corporation.—The net sum available for 1910 is £24,594, and, after setting aside £5,000 for depreciation and meeting debenture interest, a 5 per cent. dividend is declared on the ordinary shares, carrying forward £1,002. Since the installation of turbine generating plant there has been a considerable reduction in the generating costs.

County of London Electric Supply Co.—Mr. J. B. Braithwaite presided at the annual meeting on Monday. The result of the trading for 1910 was given in our last issue. The Chairman remarked that it has not yet been possible to link up the northern and southern stations, owing to the formalities required in connection with the consents of various authorities, but all these were now practically settled with. After a reference to the position with regard to street lighting in Holborn, the facts of which have already been given in our columns, the Chairman mentioned the London Electric Supply Act of 1908, and in reply to questions assured the shareholders that it was by no means a dead letter. The companies and local authorities were now considering a well-thought-out scheme, and they preferred to go slowly rather than have a hasty and patchwork system which might have to be undone afterwards. All the companies were quite alive to the position, and the County Company had interchanged *pourparlers* with one or two of its neighbours with regard to supplying electrical energy in bulk, which was permissible for the first time by the 1908 Act.

The Batti-Wallahs' Society.—The annual general meeting of this Society will take place on Wednesday, March 29th, at the Golden Cross Hotel at 8 p.m. Nominations for officers and committee should reach the Secretary before 20th inst.

Messrs. Drummond Bros. Employés Dinner.—Last Friday Messrs. Drummond Bros., Ltd. (Churchhill Works, near Guildford, Surrey), entertained their employés, to the number of over 250, to dinner at the Large Hall, Guildford. The chairman of the company, Mr. E. E. Pullman, presided, and was supported by Mr. A. Drummond, managing director, and other officials of the firm. The Mayor of Guildford was present. In one of the speeches Mr. Triggs Turner gave a very interesting *résumé* of the history of the firm, which, starting about ten years ago with a man and a boy, had made continuous and rapid progress until now the buildings covered 1½ acres, and about 250 hands were employed. He attributed their success to the fact that they supplied a useful article at a reasonable price. They had now agencies in nearly every country in Europe. During the proceedings a presentation of a silver tea and coffee service was made to Mr. A. Drummond, and the opportunity was taken to contradict the rumour that he was about to leave the firm.

SUMMARY

A discussion at the Institution of Electrical Engineers on cable laying and jointing, in connection with the Paper published in our last issue, appears on page 151, and the whole subject is critically reviewed in an article on page 147.

At the annual meeting of the National Electrical Manufacturers' Association, a very active year's work was recorded. (Page 148.)

The petition in the action by the Attorney-General of the United States against thirty-five firms for alleged unlawful combinations to obtain the monopoly of, and prevent competition in the sale of, incandescent lamps, contains some interesting information with regard to the purchase by the combine of the Siemens Tantalum and the Auer, Just-Hanaman, Kuzel, and Bergmann tungsten lamp patent rights in America. (Page 148.)

Messrs. Evershed & Vignoles have introduced an instrument on a similar principle to the megger for the measurement of very low resistances. (Page 149.)

A short article describes a new design of electromagnetic crane brake. (Page 150.)

A number of visitors were given the opportunity of inspecting the equipment of the National Physical Laboratory last week. Notes on some of the new apparatus and a brief review of the past year's work are given on page 150.

A Paper by Mr. P. Dawson was read last week before the Institution of Civil Engineers, on the electric working of the South London line of the London, Brighton, & South Coast Railway. The equipment was fully described, and results of tests and actual running were given. (Page 152.)

Three electrically-driven fire-escapes have been supplied to the L.C.C. Fire-Brigade, and are now in use. These have hub motors of the well-known Mercédès pattern and Tudor batteries. The vehicle weighs 5 tons 5 cwt., complete with escape and five men, and attains a maximum speed of 26 miles per hour on the level. (Page 153.)

In the Appeal Court on Monday, the Master of the Rolls and Lords Justices Fletcher-Moulton and Buckley reversed the judgment of Mr. Justice Ridley for £12,000 damages in respect of certain statements made by Sir John Benn concerning the G.B. system in the Mile End Road. The reason for the Appeal Court decision is that the libels were not personal upon Messrs. Griffiths and Bedell, and the jury having been unable to find special damage, the question of trade libel did not arise. (Page 153.)

In a Paper read before the Birmingham Section of the Institution of Electrical Engineers, Mr. S. P. Smith dealt with the characteristics of turbo-alternators with cylindrical rotors, calling special attention to the ease of obtaining a pure sine wave of E.M.F. on load. The concentration of the field winding giving the best result, and standardisation were also discussed. (Page 154.)

A new process for regenerating old storage battery plates is being applied with considerable success. Of a number of 46-cell regenerated traction batteries in use by a London electric carriage company, one has completed its life with 4,500 miles, which is 1,000 miles above the average figure for a new battery. The cost of such a battery is less than one-half that of a new one. (Page 155.)

Among the specifications published by the Patent Office on Thursday last was one by the British Thomson-Houston Co. for leading-in wires of drawn tungsten for incandescent lamps. Brown, Boveri & Co. have applied for permission to amend the claims of two important patents relating to the automatic speed

Hosted by Google

control of electrically-driven ring-spinning machines. A patent by C. L. Buckingham for a printing telegraph apparatus for high-speed telegraphy expires on Thursday next, after the full life of fourteen years. (Page 156.)

THE Marylebone Electricity Committee have agreed to the assessment of their undertaking being increased by £8,500.—Sir David Harrel has been appointed arbitrator in the Manchester Tramway dispute.—Flame arc lamps are to be used on the Victoria Embankment.—The Dolter system at Torquay has now been changed over to the trolley system.—The proposal for a company to construct tramways between Huddersfield and Halifax has fallen through.—The electrification of the Dublin and South Western Railway has been suggested. (Page 157.)

A STEAM turbo-alternator and condensing plant is required at Glasgow; high and low-tension switchgear and static transformers at Hammersmith; a steam alternator and motor generator at Rawtenstall; and a turbo-generator, condensing plant, switchgear and motor generator at Torquay. Loans of £2,083, £3,000, and £20,000 are to be taken up at Hastings, Dublin, and Bermondsey. Cables are required at Watford; and a third section of the L.C.C. Central Car Depôt is to be built. (Page 157.)

THE arbitrator in the dispute between the Underground Electric Railways Company of London and the Westinghouse Company concerning the substitution of Parsons turbines for Westinghouse machines has given his award. (Page 159.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, MARCH 23RD.

Institution of Electrical Engineers.

8 p.m. "Electricity Meters," by H. A. Ratcliff and A. E. Moore.

FRIDAY, MARCH 24TH.

Physical Society.

5 p.m. At the City and Guilds (Engineering) College, South Kensington. (1) "Experiments on the Measurement of Electrolytic Resistances using Alternating Currents," by H. F. Haworth. (2) "Oscillatory Currents in Coupled Circuits" and "Some Radio-telegraphic Apparatus in use at the City and Guilds (Engineering) College," by Prof. G. W. O. Howe.

Institution of Civil Engineers.

8 p.m. At 25 Great George Street, Westminster. "The Uses of Chemistry in Engineering," by Mr. James Swinburne.

Electro Harmonic Society.

8 p.m. Smoking Concert at Holborn Restaurant.

SATURDAY, MARCH 25TH.

Association of Mining Electrical Engineers.

3.30 p.m. *Notts and Derbyshire Branch.* At University College, Nottingham. (1) "The Use of a Milli-ampere Testing Set," by E. E. Beadsmore. (2) Discussion on the new Home Office Regulations.

3.30 p.m. *Warwickshire and S. Staffs Branch.* At Imperial Hotel, Birmingham. "Three-phase Motors for Haulage in Mines," by J. Simpson.

Association of Engineers-in-Charge.

Annual Dinner at Holborn Restaurant.

MONDAY, MARCH 27TH.

Institution of Electrical Engineers: Newcastle Branch.

7.30 p.m. At Armstrong College. "Wireless Telegraph Working in Relation to Interferences and Perturbations," by J. E. Taylor.

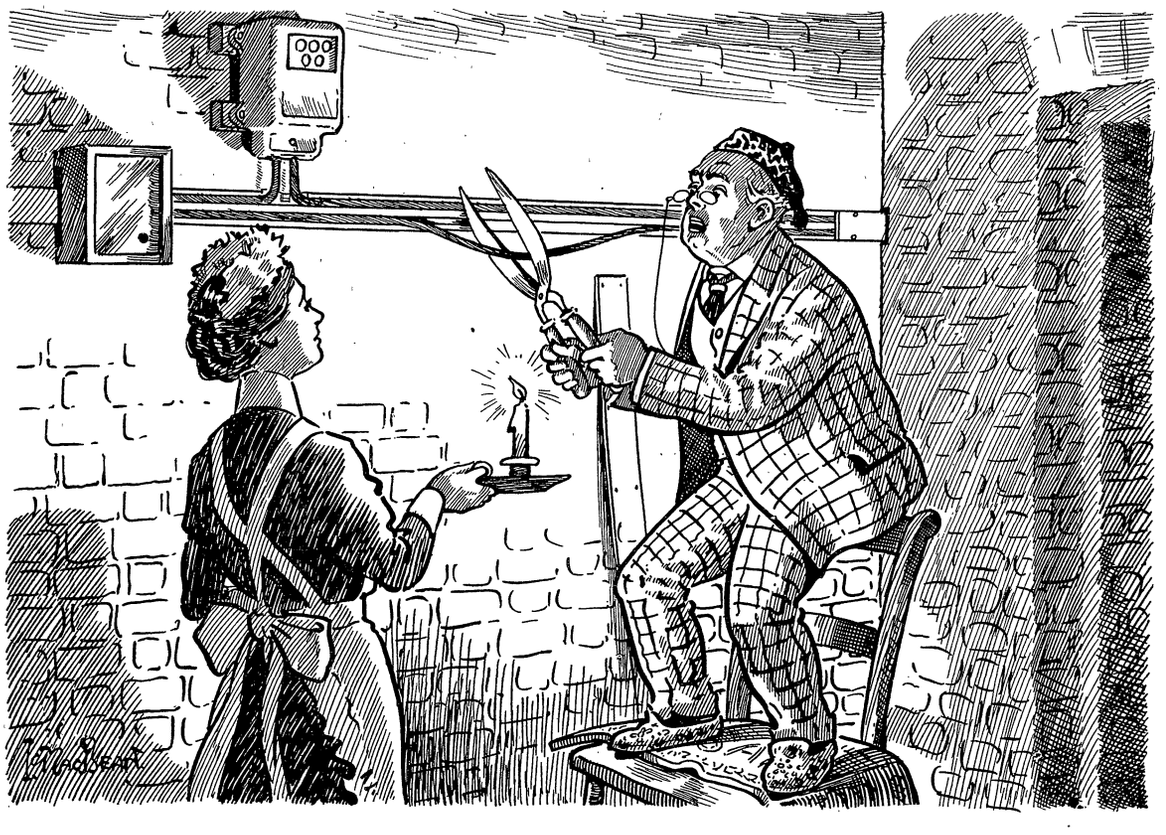
Royal Society of Arts.

8 p.m. Cantor Lecture IV. :—"Applications of Electric Heating," by Prof. J. A. Fleming, F.R.S.

TUESDAY, MARCH 28TH.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. Annual General Meeting, at University. "The Properties of the X-Rays from Radio-active Matter," by **Prof. E. Rutherford.**



Institution of Civil Engineers.

8 p.m. Further discussion on "The Electrification of a Portion of the Suburban System of the L.B. & S.C. Rly.," by P. Dawson.

FRIDAY, MARCH 31ST.

Institution of Civil Engineers.

8 p.m. Lecture II. :—"The Uses of Chemistry in Engineering," by J. Swinburne, F.R.S.

IRATE CONSUMER:—They told you the current returned to the works through this wire, did they? No wonder my bill's high. We'll see what *this* will do!

MAINS

WHEN a keen controversy exists in engineering circles as to alternative systems or designs, it is usually safe to assume that both have their merits, and that it is a competition of excellence, rather than a question of choice between two tools neither of which is precisely adapted to the work in hand; when the difference of opinion is with regard to the selection from three methods, this is almost invariably due to an *embarras de richesse*, rather than to an inadequacy of means. Such is the case in the triangular duel between the advocates of the "draw-in," "solid," and "direct-in-ground" system of cable-laying, which was resumed at the Institution of Electrical Engineers in connection with a Paper on cable laying and jointing. A report will be found in our issues of last week and to-day. Mr. Vernier, the author of the Paper, whose experience in laying high-tension transmission cables for the Newcastle power systems has been considerable, is an advocate of a direct-in-ground system, and in this he was supported by Mr. Welbourn, of the British Insulated & Helsby Cables, Ltd. Mr. Highfield, Engineer and Manager of the Metropolitan Electric Supply Co., prefers a draw-in system. Mr. Roger Smith, of the Great Western Railway, and Mr. J. F. C. Snell favoured the solid system. Opinions are also divided in the case of engineers of electricity supply undertakings, but among them the solid system enjoys the greatest popularity—partly on account of the fact that the Local Government Board has decided that loans for "direct-in-ground" mains must be redeemed in 15 years, whereas 25 years is the official life of mains on the solid system.

Looking at the matter broadly, it is clear that there must be less waste of material and labour if the cable is protected adequately before it is laid, and is then placed at a sufficient depth under the soil. If the lead covering and armouring are liable to be acted upon chemically, we must protect them in their turn with a suitable covering. This is in effect the process advocated by Mr. Vernier. But even his specification—which brings up the cost of the laid cable to that of the solid system—the compounded jute, which forms the outside envelope of the cable, will resist the action of certain soils no more than the armouring which it covers, and to make the latter proof against the navvy's pick would entail a costly construction similar to that of the shore-end of a submarine cable. On the other hand, when the cable is to be laid in soil that will have no action on lead and unlikely to be disturbed frequently by the muscular navvy, a lead-covered cable, with a light armouring sufficient to prevent damage during laying and reinstating the ground, and covered with a tarred plank, is certainly all that is needed in ordinary circumstances.

The solid system, if properly laid, has, however, the advantage of affording protection against the unknown and unforeseen. If the soil is so varied that its chemical properties cannot be assumed—especially if ashes may be present, or in recently "made" ground—it is risky to lay on the "direct-in-ground" system. Notwithstanding Mr. Vernier's and Mr. Patchell's eulogism of clay, this material is a snare, and we know of a case in which a beautifully soft puddle clay, fetched for the purpose and carefully placed at the bottom of the trench in a thick layer, so that the cable was absolutely embedded in it, acted upon the lead with as much certainty as a weak solution of nitric acid would have done. It is true that the solid system is not always an absolute protection for every inch of the cable. If completed under such conditions as were depicted by our cartoon artist last week, there might well be blow-holes in the bitumen filling, but, in ordinary circumstances, the chances of the position of an occasional blow-hole or serious shrinkage coinciding exactly with the presence of chemically active soil or "bad" water, is sufficiently remote. The comparative immunity of solid systems from breakdown, in fact, has been their own recommendation. The chief source of danger to be guarded against occurs on very large mains, which have to be heavily fused. Cases have been known in which short circuits have resulted in the volatilisation of the compound accompanied by volcanic eruptions from manholes, and even the flow of boiling compound along the services and into houses. Such occurrences, however, have been rare.

The draw-in system has its uses and also its abuses, its users and its abusers. In many cases it cannot be beaten for feeders and transmission cables; in others it can conduce to the presence of a permanent film of moisture around the cable, or accommodate an explosive mixture of gas and air along a length of street. A point to be remembered is that it should be a draw-out system as well as a draw-in system. If it taxes the winch and the available man-power to the utmost to draw in the cable, one of the chief advantages of the system is lost. Mains engineers should also profit by the experience of telephone engineers in preferring stoneware or cement ducts to iron pipes. With properly laid and bonded iron pipes there should be no electrolytic action on the cables, but sometimes there is, notwithstanding.

In reading Mr. Vernier's remarks about jointing, it must be remembered that, although many of them are of general application, he deals essentially with important high-tension transmission cables. For ordinary towns work, the lead sleeve joint, necessitating as it does highly efficient plumbing and careful superintendence, is less frequently employed than the joint-box with "compound glands." No matter which joint is used, however, the shrinkage of the bitumen or compound filling, on cooling must be borne in mind. Some compounds shrink less than others, but it is obvious that when the filling has assumed its solid or viscous state it will occupy less space than when it was poured in at a high temperature. Unless, therefore, a further quantity of the filling is poured in after the mass in the sleeve or joint-box has cooled, a vacuum is left, and any slight flaw in the lead joint, or, in the case of boxes with compound glands, any cracking or shrinkage of the compound in the pocket along the lead of the cable will result in water being drawn in in wet weather. We have actually observed this phenomenon in lead-sleeve joints plumbed to the lead of the cable by wiped joints, in cases where a porous plumbing metal had been employed without sufficient percentage of tin, and have actually boiled a quantity of water out through the "wipes" on a number of joints in succession, although these were laid in well-drained soil.

Both of the new conductor joints described by Mr. Vernier—the rigid one with copper braid, and the expansion joint—are admirable, and the method of insulating he described also seems applicable for all straight-through joints, whether for single or 3-core cables. For concentric cable, and even triple-concentric, the employment of narrow bands of tape, such as Mr. Vernier suggested for 3-core cable, would seem to be applicable if the jointing of the conductors is arranged so that the compound can run right through. The remarks made by Mr. Highfield as to the handling of the insulating tape are of interest; in this connection it may be noted that boiling plain tapes in oil, and wrapping them on when hot removes the moisture from handling, especially if boiling compound is poured over the insulated joint before the lead sleeve is drawn over.

We have reviewed the principal points of the Paper

Hosted by Google

and discussion in this article, but there are numerous other matters of detail of considerable interest which were dealt with. For instance, although no new theory was put forward as to bonding, or in connection with protection against surgings, the remarks on these subjects should be read by mains engineers. In fact, the whole Paper and discussion deserve careful perusal.

THE NATIONAL ELECTRICAL MANUFACTURERS ASSOCIATION

THE annual meeting of this Association was held on February 28th last, at the Institution of Electrical Engineers. The Chairman, Mr. H. W. Butler (Electrical Power Storage Co., Ltd.), said that the membership, now over eighty, had practically doubled itself in the last twelve months. He commented appreciatively on the activity displayed by the Northern section, and proceeded to deal with some points in the report. A joint committee of the Incorporated Municipal Electrical Association and themselves was about to consider the question of objectionable clauses in contracts, and great progress had been made as regards the Olympia Exhibition, for which practically all the ground-floor space was now allotted. Unfortunately, their efforts to promote a joint exhibit with the Board of Trade at Turin had not been successful. Mr. H. H. Berry seconded the adoption of the report. Mr. F. H. Nalder also spoke, and Mr. H. Bevis referred to the decision of the Institution of Electrical Engineers to revise their model general conditions of contracts, and to publish them in a form that would appeal to town clerks as well as municipal engineers. Mr. B. Longbottom dealt with the work of the Northern section. Mr. D. N. Dunlop suggested the appointment of an assistant secretary, and the report and accounts were then adopted. The following council and general committee have been elected :—

Council :—Berry Skinner & Co.; British Westinghouse Electric & M'f'g Co.; Bruce Peebles & Co.; Electrical Power Storage Co.; Electromotors, Ltd.; Elliott Brothers; Ferranti, Ltd.; General Electric Co.; International Electric Co.; Lancashire Dynamo & Motor Co.; A. & P. Lundberg & Sons; Nalder Bros. & Thompson; A. Reyrolle & Co.; Sunbeam Lamp Co.; Vickers, Sons & Maxim.

General Committee :—Berry Skinner & Co.; Croggon & Co.; Crompton & Co.; Electrical Power Storage Co.; Electromotors; General Electric Co.; International Electric Co.; Gilbert Arc Lamp Co.; Hart Accumulator Co.; Pirelli, Ltd.; Sterling Telephone & Electric Co.; Union Electric Co.

Institution of Post Office Engineers.—At a meeting on March 13th, a Paper on Small Prime Movers was read by Mr. H. P. Riner Moore. After some introductory remarks on the principles of the steam turbine, he described the main features of small reciprocating engines, dwelling on the use of the indicator and methods of governing, and passed on to a consideration of gas, oil, petrol, and alcohol engines. Messrs. E. W. Rees, J. Coxon, and D. H. Kennedy took part in a brief discussion.

Colliery and General Mining Exhibition, Manchester.—Arrangements are well advanced for the Colliery Exhibition at Manchester, organised by *The Engineering Review*. The opening date is now May 12th, and the Exhibition will close on Saturday, May 27th. Practically no space is now left, as a great rush of applications followed on the announcement of the change of date, which was decided in consequence of the Annual Conference of the Colliery Managers' Association of Great Britain being held in Manchester during May.

Speed Regulation of Shunt Motors.—A Paper by Mr. E. W. Short, published in the *Journal* of the Institution of Electrical Engineers, discusses the inherent speed regulation of D.-C. shunt motors. The author points out that although a shunt motor may be so designed, and its voltage drop and brush position so adjusted that it runs at the same speed on no load and on steady full load at any given temperature, yet the speed of the same machine will vary very considerably when working on a rapidly varying load such as met with in driving textile machinery, where it is highly important that the speed should be constant. The results of a number of tests in a spinning mill are given, and the author then shows from a consideration of the mutual induction between the armature and shunt windings, and between the series and shunt windings in the case of a compounded machine, that the changes in flux necessary to keep the speed constant with varying load cannot occur instantaneously, the result being that the speed may vary as much as 5 per cent. up and down. The case of a 35-h.p. motor is worked out in detail, curves being deduced to show the actual conditions under a rapidly varying load.

THE AMERICAN INCANDESCENT LAMP COMBINE

THE action brought by the Attorney-General of the United States against the General Electric Co., of America, the National Electric Lamp Co., the American Westinghouse and thirty-one other electrical and manufacturing companies for alleged unlawful combinations to restrain trade, is dealt with at some length in the *Electrical World* of New York, for March 9th. It is pointed out that, apart from the effects of the action upon the companies concerned, two highly important issues are raised. First, the extent to which the monopoly awarded by a patent may be extended, and secondly, whether any limitations can be imposed upon a manufacturer in the purchase of patents to strengthen his position.

It is stated in the petition that agreements have been made between the General Electric and National Lamp companies and Siemens & Halske A.-G., of Berlin, whereby the former acquired the exclusive right to manufacture and sell tantalum lamps under the German Co.'s patents, the filaments being purchased in Germany. Another agreement between the same two American companies and the Deutsche Gasglühlicht Gesellschaft (Auergesellschaft), of Berlin, secured the exclusive rights of the U.S.A. tungsten lamp patents owned by the Auergesellschaft. By a contract with the Bergmann Elektricitäts Gesellschaft, in 1909, this company agreed to cease importing lamps under the Bergmann patents into the United States, and in the same year the two American companies purchased the American rights of the Just-Hanaman and Kuzel patents, thus practically securing a monopoly of the metal filament lamp trade. In the first two cases, the consideration was a cash payment of £50,000 and £20,000 respectively, together with a royalty on every lamp sold, but the Just-Hanaman and Kuzel patents were apparently bought outright for £50,000 and £48,000 respectively.

Referring to the trade in carbon filament lamps, the petition states that although the carbon filament lamp patent expired in 1894, the combined companies have secured the monopoly of this trade also, by compelling dealers and contractors who enter into contracts with them for the purchase of tantalum and tungsten lamps, to purchase from them also all carbon filament lamps they may require.

Several unlawful acts by the defendants to hamper independent companies are alleged, including the sale of inferior lamps at greatly reduced prices, and contracts with manufacturers of machines, glass bulbs, caps, and other accessories used in lamp manufacture, requiring them to refrain from business with independent firms or to sell to them only at excessive prices. As the defendants now do over 97 per cent. of the lamp business, it is stated that both these manufacturing companies and the independent lamp companies are put in an unfair position.

Finally, it is urged that the combination has the effect of keeping up the prices of both metal filament and carbon filament lamps much higher than those obtaining in other countries, by preventing competition; and, as an example, it is mentioned that of fourteen tenders received for the supply of 340,000 lamps of various kinds to the United States Navy, thirteen were identical in amount, thus showing that the price was fixed in advance.

Association of Students of the L.C.C. Engineering College, Poplar.—A visit was paid to the Elephant and Castle sub-station of the L.C.C. tramways on February 18th, and a Paper on sub-station working was read at a meeting on February 25th.

Wireless Telegraph Notes.—The Eastern Extension, Australasian & China Telegraph Co., and Marconi's Wireless Telegraph Co. announce the opening of a wireless telegraph station at Keeling-Cocos Islands for communication with ships at sea. The radius of the apparatus which has been installed is 250 nautical miles.

According to the *Times* Berlin correspondent, a company has been formed to develop Herr Goldschmidt's system of wireless telegraphy. The company, which is to be called the Hochfrequenz-Maschinen Aktiengesellschaft für Drahtlose Telegraphie, has a share capital of £105,000, but no shares are to be issued to the public at present. The presidents of the company are Vice-Admiral Emsmann and Herr Goldschmidt, together with representatives of the Commerz und Disconto-Bank and the Lorenz Company, both of which are largely interested.

Phase Displacements in Synchronous Machines.—In our report on March 9th of the discussion on Mr. Firth's Paper at Newcastle on the above subject, Mr. Leake was incorrectly given as the second speaker. As a matter of fact, Mr. Leake himself was not present, but his suggestion of plotting phase displacements against total load was only quoted by Dr. Thornton, by whom the subsequent remarks were made. The second speaker was thus Mr. Maccall.

THE DUCTER: AN INSTRUMENT FOR MEASURING LOW RESISTANCES

FOLLOWING the justly deserved success of their well known "Megger" for the measurement by direct reading of insulation and other very high resistances that can be expressed in megohms, and of its modification, the "Bridge-Megger," for moderate resistances conveniently described in ohms, Messrs. Evershed & Vignoles (Acton Lane Works, Chiswick) have turned their attention to the production of an instrument of similar simplicity of reading for the measurement of very low resistances, such as can be conveniently expressed in microhms or millionths of an ohm. This, like the megger, is provided with a pointer to read the resistance direct, and its five separate ranges enable resistances from 10 microhms to 5 ohms to be measured. The apparatus should be of great use in comparing contact resistance of switches, testing all sorts of joints, bonds, and connections, the sampling of conducting material, as well as

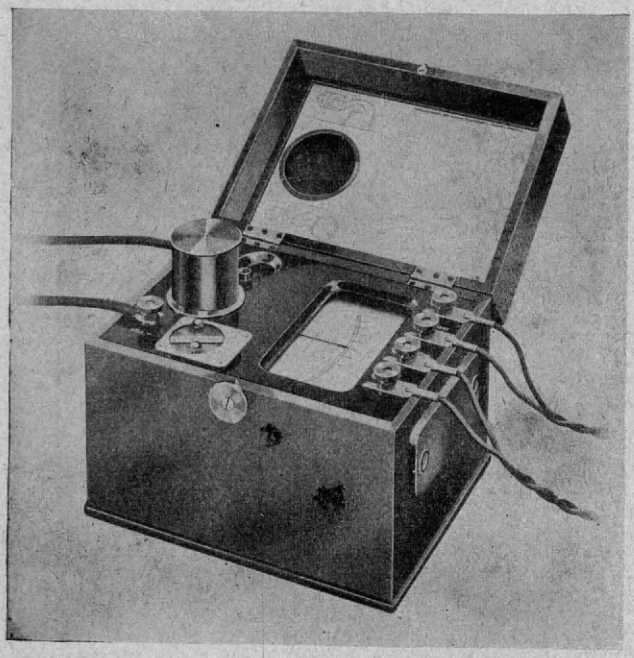

Fig. 1.—General View of Instrument.

measuring resistances of various parts of machines without loss of time. For comparing various forms of cable clamps it should be invaluable.

Speaking generally, the instrument works on the same principle as its elder brother, the megger. The moving system is composed of two coils, in planes at an angle to each other, carrying currents proportional to that passing through the resistance to be tested and to the drop of potential across it respectively. This system is free to swing in a permanent magnetic field, and the position which these coils and the pointer take up depends on the direction of the resultant of the forces due to the currents in the two coils, and is thus determined by their ratio, which is proportional to the resistance to be tested. The main differences are, however, due to the fact that whereas in the megger the drop of potential amounts to some hundreds of volts and the current through the resistance is infinitesimal, in the ducter a series current measurable in amperes is employed, but only a diminutive drop is produced. Thus the working current is supplied from a few accumulator cells instead of from a high-voltage generator, and suitable shunts are employed in connection with the current coil. There is another difference due to the fact that a much more open scale is required at the lower readings in the ducter than in the megger, and this is obtained by suitable shaping of the pole pieces of the permanent magnet and the fixed core within the coils, and slight differences in the construction of the voltage coil. The five ranges are put in action by a switch, which simply cuts in and out suitable resistances and shunts. The scale is calibrated to read direct from 0 to 500 microhms, and has nearly equal divisions. The switch has positions corresponding to multipliers of 1, 10, 100, 1,000, and 10,000. There is also an "off" position. It will

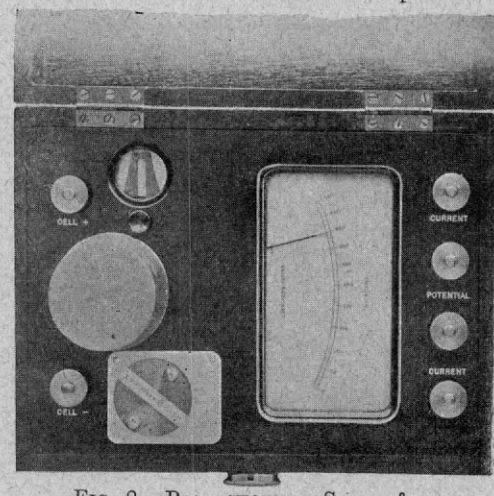

Fig. 2.—Plan showing Scale, &c.

readily be understood that with an unknown resistance to be tested, if the switch is on an unsuitable step, not only may the needle be sent hard over, but a current of sufficient magnitude may pass through the coils to burn them out. The problem of obtaining the required range without this danger was one of the most serious met with in designing the apparatus. The difficulty has been overcome by the provision of a sensitive polarised magnetic cut-out, which immediately opens when the current exceeds a safe value and thus protects the coils. Except for the features already mentioned, and the fact that the swinging coils are provided with a phosphor-bronze strip suspension, with jewelled guides not requiring accurate levelling, instead of pivots, there is much similarity in the construction with that of the indicating portion of the megger. Fig. 1 gives a view of the instrument itself, and the pointer and scale, the range switch, the safety cut-out, with the push button for resetting it and the arrangement of the terminals are also seen in Fig. 2. The projecting brass case between the cut-

X. Resistance under Test.
H, G. Potential Contacts.

out and the switch is simply the cover of the suspension of the coils. A general diagram of connections is given in Fig. 3.

The battery consists of four small accumulator cells of 10 ampere hours capacity each and is contained in a separate box. A switch enables either all four cells to be put in parallel to give 2 volts, or in series to give 8 volts, according to the resistance to be tested. A separate compartment is provided in the battery box for the leads and contact spikes,

Hosted by Google

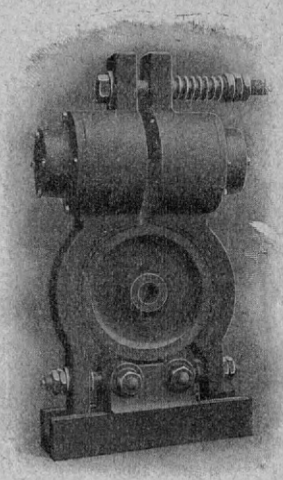
so that nothing more than the two boxes is required to complete the outfit.

Particular attention may be drawn to the points provided for making contact with the resistance to be tested. These are mounted on handles at the end of flexible leads, each carrying a circuit and potential point. These are telescopic and have sharp pyramidal points, which while pressed home against a spring turn round like an archimedian drill, and thus render the contact self-cleaning. To take a reading, all that has to be done is to take one handle in each hand and press the contacts on to the points between which the resistance is to be tested, and, having found the most suitable range, to read off the result. When testing numerous switches, &c., it is sometimes more convenient to use separate current leads in the ordinary way, connecting up a number in series, and using potential contact points only to take successively the resistances at the various parts required. For example, it can readily be found how the total resistance of a switch is divided up between the contact resistance at its terminals, the actual switch contact, and the metal of the blades and other parts.

The apparatus is quick to use, dead beat, and it is important to notice that its accuracy is practically independent of the constancy either of the permanent magnet nor of the battery voltage. To say that the workmanship is equal to that of the megger is sufficient praise, and a visit to Messrs. Evershed & Vignoles works, where it is made, showed us that as much care has been expended on the methods of manufacture of the upwards of 900 parts of which it is composed as on the suitability of those parts for the work they have to perform. There is, we believe, no other instrument with which measurements of low resistance can be made with such expedition and accuracy, and its utility is such that a very large demand may confidently be expected.

THE NATIONAL PHYSICAL LABORATORY

On Friday last, the occasion of the annual meeting of the General Board of the National Physical Laboratory, a number of invited visitors were given the opportunity of inspecting the Laboratory buildings at Teddington and their equipment. The guests assembled in the Experimental Tank Building, where they were received by Sir Archibald Geikie, President of the Royal Society and chairman of the General Board of the Laboratory, Lord Rayleigh, chairman of the Executive Committee, and Dr. R. T. Glazebrook, Director of the Laboratory.



A great deal of interest naturally centred round the National Experimental Tank, the equipment of which is now nearly complete. The main tank is 550 ft. long, 30 ft. wide, and 12 ft. deep, and is spanned by an electrically-driven travelling carriage running on rails on either side, which will be able to tow models up to 20 ft. in length at speeds up to 17 m.p.h. The carriage was equipped by Messrs. Dick, Kerr & Co., and weighs about 14 tons, and is driven by four special vertical shaft motors through worm gearing, taking current from trolley wires running alongside the tank. A controller is provided on board, but normally control will be effected from switchgear on shore. The arrangement of connections is somewhat elaborate, and provision is made for very accurate adjustment of the speed by regulation of the fields of the motors, which are separately excited from a motor generator. Separate trolley wires are thus required for the field circuits, and these are exceptionally heavy to avoid variations of drop of potential. Special machinery is provided for shaping the wax models used.

Dr. Glazebrook also drew special attention to the aeronautical work now being carried on for the Advisory Committee. The special apparatus includes the large whirling table for experiments with model propellers and the effect on the air of objects of various forms, a subject also studied in an experimental wind chamber and by analogy in tanks of running water. Practically all this apparatus, some of which represents extraordinary ingenuity, is electrically driven, and, indeed, it is difficult to see how research of this kind could have been carried out before electrical appliances were available.

Turning now to the more exclusively electrical aspect of the work of the Laboratory during the past year, mention must be made of the comparisons of international standards made by Mr. F. E. Smith, who visited the Laboratorie Central d'Electricité in Paris, and the Bureau of Standards at Washington; representatives of St. Petersburg and Japan also visited Teddington, and as a result of these researches, the E.M.F. of the Weston standard cell is to be taken as 1·0183 volts at 20° C. Progress has also been made with the new Lorenz machine, which now only awaits some final measurements, and Mr. Campbell's hysteresis and eddy current tests, and his measurements on wavemeters have been continued. In the photometric division, a great deal of work has been done with a view to establishing a series of metal filament sub-standards, and a large number of specially made Osram lamps, supplied by the generosity of the General Electric Co., have enabled "cascade" observations with lamps running at graded efficiencies to be taken to surmount the colour difficulty. Interesting work is also being done in this department by Mr. Patterson, of the Board of Trade, regarding the standardisation of visibility of ships' lights. A number of investigations of suitable methods of testing have been carried on in the Electrotechnical Department, and among subjects upon which experimental work of great utility has been carried out, may be mentioned the effect of railway travelling on meters, the heating of lamp holders used for radiator lamps, and a long series of investigations into the dielectric properties of micanite, ebonite, and other insulating materials. The department gave assistance regarding the display of instruments in the British Section of the Brussels Exhibition, and most interesting results have been obtained by Mr. Rayner in his insulation research for the Engineering Standards Committee. A large amount of ordinary test work has also been carried out, but not quite as much as in 1909, and at the request of the Wiring Rules Committee of the Institution of Electrical Engineers, the tests to determine the temperature rise in the current of various sizes of cables with different styles of covering have been extended. An investigation has also been in progress for the Admiralty on the temperatures to which resistance alloys can be subjected without deterioration.

Electrical methods, of course, enter largely into the work of other departments, of which space prevents more than a passing mention here. Great progress is being made in the department of thermometry in high temperature research, and furnaces are now available up to 2,500° C. There has also been a great deal of activity in the metrology department, where a good deal of new and interesting apparatus for standard measurements was open to inspection. In this department 13,918 taximeters were tested in 1910; all those in use on London cabs are tested before taking into use. The whole establishment bears an atmosphere of great activity, the building of large extensions is in progress. The staff numbers over 130 persons, and, in addition to research and general experimental work, over 28,000 tests have been made at Teddington during 1910, of which 1,810 were in the Electrotechnical Department. The total income of the Laboratory for that year was £28,076, of which £15,363 was the net amount received for work done, and the total expenditure was £28,298.

AN ELECTROMAGNETIC BRAKE

Witton-Kramer Electromagnetic Brake.

The Witton-Kramer Electric Tool & Hoist Co. (Witton, Birmingham) have introduced the form of brake illustrated here to meet the demand for an entirely self-contained outfit which can be applied to existing couplings, &c., of electric motors, hoists or lift gears, rolling-mill machinery, and machine tools generally. They can be used either as holding or lowering brakes, and will work in any position. The shoes are leather lined, and adjustable for wear. The magnets are arranged to push the blocks apart when the current is on, while normally the brake is held on by a spring in the usual manner. This design is only used for continuous current.

British Gas-power Plant for Japanese Electric Railway.—The Power-Gas Corporation, Ltd., of Stockton-on-Tees, have received an order from the Japanese Government for a large gas-power plant for an electric railway between Tokio and Yokohama. The company inform us that the contract is well over £100,000, and may reach £150,000. The producer plant will consist of three units, each of three Mond-type gas generators, and fitted with apparatus for the recovery of sulphate of ammonia. Inferior coal with nearly 20 per cent. ash will be used. The engines will be supplied by the Lilleshall Co., Ltd., and will have two double-acting cylinders placed in tandem. They will be direct coupled to Dick, Kerr alternators of the flywheel pattern generating at a frequency of 25 cycles. Power will be conveyed over a high-tension line to sub-stations along the railway route.

Glasgow Local Section of the Institution of Electrical Engineers.—At an informal meeting of the Glasgow Local Section of the Institution of Electrical Engineers on Tuesday of last week, the announcement was made that the area embraced by the Section had been extended to include Edinburgh, Leith, and district. Mr. Sam Mavor welcomed the new members thus taken in, and Prof. Baily, of Edinburgh, responded.

CABLE LAYING AND JOINTING

THE following is a report of the discussion on Mr. C. Vernier's Paper on "The Laying and Maintenance of Transmission Cables." The Paper itself was published in slightly abbreviated form in our last issue:—

DISCUSSION IN NEWCASTLE.

Mr. STEDMAN questioned the use of tape and braid as a protection for lead-covered cables, as the covering absorbed and retained moisture, which, if charged with chemicals, would act upon the lead.

Mr. VESEY BROWN said that to switch in 19 miles of cable on a H.-T. circuit was contrary to first principles, and he thought that Mr. Vernier had not stated all the circumstances. Would it not be cheaper to instal simple charging devices rather than to spend the money on the necessary extra insulation?

Mr. J. ROBB said that the worst case of expansion which the Post Office engineers had had was on the Forth Bridge, but the difficulty had been got over by leaving bights in the cable. He advocated the use of petroleum jelly when drawing cables into ducts, not only as a lubricant, but as a means of preventing electrolysis.

Mr. C. TURNBULL did not favour black bitumen compound, as it was apt to become full of holes. He used a yellow viscous compound, which had stood successfully for ten years. He did not approve of bonding the cable coverings to water-pipes and tram-rails, and his practice was to earth at the station only.

Mr. F. O. HUNT suggested that breakdown occurring some time after a surge had taken place was due to the cumulative action of surges at intervals gradually weakening the insulation.

Mr. J. B. JOHNSON believed in draining each manhole into a sump consisting of 2 ft. of 9-in. earthenware pipe, and also in caulking covers with yarn and sealing with a mixture of grease and whiting.

Mr. W. R. MORTON said that taped and braided cables were extremely difficult to pull out of conduits after a few years' service. The chief disadvantage of asphalt troughing was its price, but it ran cooler than any other type, except perhaps armoured cable laid direct.

Mr. P. V. HUNTER confirmed that the 19 miles of cable referred to was switched in direct, and that no surges due to switching in had occurred.

Mr. SLOAN also spoke.

Mr. VERNIER, in the course of his reply, said that the 19 miles of cable referred to had latterly been fitted with lightning arresters by the contractors, who had suspicions of surges, but the arresters had never been called upon to act so far as he knew. He could not understand how petroleum jelly could prevent electrolysis, as the armouring and iron pipe were in electrical connection, and the armouring could not be affected until the pipe had been eaten through. He thought that an instantaneous rise of pressure of 200,000 to 300,000 volts when switching in a long 20,000-volt cable was quite within reason, and cables should be able to withstand this momentarily. All the advertised soldering fluxes which he had had analysed contained acid, and his practice was to use pure resin or a mixture of resin and tallow.

DISCUSSION IN LONDON.

Mr. J. F. C. SNELL, after referring to some mains laid on the Howard solid system in which chemical impurities in the soil had corroded away the steel surrounding the asphalt, but had left the asphalt intact, mentioned the case of two 6,600-volt three-core 0·1 sq. in. armoured cables laid along a steep embankment, the soil of which had subsequently slipped and had left the cables hanging for a distance of forty yards, but they not only kept up their stoneware trough, but also something like 18 in. of clay, and stood the strain admirably. Experiments carried out by himself and Mr. Digby had resulted in a certain specification for bitumen-filling which had been used with great satisfaction. Bitumen had to be softened by the addition of a certain oil, and must be free from wood and coal-tar pitch, and also sulphur compounds and resin. It must not contain more than 35 per cent. of ash, and its viscosity was to be such that at a temperature of 82° C. it began to flow, whilst at 100° it flowed freely. On the question of electrolysis, he thought the best plan was to earth the sheathing of the cable at certain definite points. He asked the author what current densities he was able to work up to with his 20,000-volt cables under emergency conditions. Particulars had been published by the American Institute of Electrical Engineers, showing that 20,000-volt cables had been run up to 1,800 amperes per sq. in., and kept within reasonable temperature limits.

Mr. B. WELBOURN (British Insulated & Helsby Cables, Ltd.) said he knew of instances in which lead-covered cables had been in existence for 21 years with practically no deterioration. He had held the opinion for many years that armoured cables were right to use when cables could be buried at sufficient depth. It was very difficult indeed to get a proper solid system where it had to be made in the streets under varying climatic conditions, and with unskilled labour, and it was a correct plan to make in a factory, and to send out ready for laying a much better solid system than could be made in the streets. The recent regulations of the Home Office Committee on the use of electricity in mines favoured armoured cables, but the attitude of the Local Government Board in the past had militated against their use for street mains owing to the short period for repayment which was allowed, namely, 15 years, compared with 25 years for the solid system. He suggested that there was scope here for the Institution of Electrical Engineers to act in conjunction with the Incorporated Municipal Electrical Association, and to educate the Local Government Board. He emphasised the importance not only of proper bonding and of earthing at certain definite points, but also of making careful periodical inspection to see that these conditions were maintained. He expressed his admiration for the author's braided joint, and also of the expansion joint. Finally he mentioned that his practice in regard to railways was to lay cables 4 ft. deep and 4 ft. away from the nearest rail, and if under a track not less than 6 ft. deep; by adopting this rule no trouble had been experienced.

Mr. J. S. HIGHFIELD (Metropolitan Electric Supply Co., Ltd.) expressed the opinion that as long as the ground was good and no fears of subsidence existed, he thought that a drawn-in system was not only cheaper, but also superior. He gave some interesting details of experiments made on joints on his system to ascertain the causes of some failures on 10,000 volt cables. It was found that by stepping the insulation of the cable ends in four or five steps instead of tapering it down, the joint was so improved that the breakdown pressure was increased from 30,000 and 40,000 volts to between 50,000 and 60,000 volts. Later they tried making the joints entirely with paper, similar to that with which the cable is insulated, and with more steps, and putting on the paper by a reel so that the men did not handle it. The effect was to raise the test pressure to 84,000 volts; in fact, they had not broken down these joints at all. He was not at all sure that cables might not be damaged by testing at twice the working pressure with alternating current, as, when making breakdown tests up to 100,000 volts A.C., there had not been a clean electrical puncture; the breakdown had been caused by the heat generated at the joint by the energy lost in dielectric hysteresis. He had tested similar joints in cables with 150,000 volts direct current, and there was no difficulty in this case because there was no heating up, and very little power was taken. He would suggest that all H.T. cables, even those intended for A.C. systems, should be tested with H.T. direct-current to avoid this heating of the cable.

Mr. W. H. PATCHELL said that he frequently had to carry clay to the spot in order to bury his cables in it. This was a necessary practice very often in colliery districts. He had got over many of the troubles in cables due to dirty handling of the jointing material in connection with the mains from Bow to London by the use of micanite tubes, and he agreed with Mr. Highfield that if it were necessary to put the tape on in the streets, it should be done from a reel, and not handled.

Mr. ROGER T. SMITH (Great Western Railway Co.) said that from the Park Royal Power Station of the Great Western Railway Co. there were 27 miles of high-tension three-core cables to the sub-stations, 10 miles beyond the sub-stations, and 14 miles of low-tension cables laid on the Howard solid system, and a test upon a 300-yard length of the high-tension cable gave a resistance of 2,000 ohms between the sheath and the earth through the troughing, which was quite sufficient to prevent any electrolysis. The cables were all laid by Messrs. Siemens five years ago, and of the 600 joints which were insulated with tape lapped on in the usual way, only one had failed during the contractors' period of maintenance, and none had failed since. The cables crossed the railway lines 27 times, in many places under the whole of the main lines from Paddington. In other places the trough rested on the crown of the arches, and between the end of the concrete bed of the trench and the bridge they were laid up a sloping sheet of steel fixed to the edge of the bridge, and anchored into the concrete. In this way vibration effects had been entirely eliminated. The only thing that had happened was that in the middle of many bridges the cables had splayed out sideways, but it had caused no trouble. With regard to the cost of maintaining this system of cables, in 1907 for 37 miles the cost was £9. In 1908 this figure increased to £30, largely due to the purchase of a tar boiler; in 1909 it was £17; in 1910, £18 10s., and the average was £18 12s., or less than one-tenth of one per cent. of the cost of the cables.

Mr. W. M. MORDEY, referring to the statement in the Paper that breakdowns were sometimes due to leakage of steam and hot water from neighbouring steam pipes, thought the author could find his explanation of why this should be so in the fact that the dielectric resistance goes down very considerably with rise of temperature.

Hosted by Google

Mr. A. HOWELL (Assistant Engineer, Hornsey Electricity Works) deprecated the use of ducts laid in concrete, as, if the extra thickness of wall was required, it could be obtained by using a thicker manufactured duct. He recommended covers of the watershed type with longitudinal channels underneath to enable the pitch to flow freely. It was a mistake to fill too great lengths at a time, and he recommended not more than 12 feet.

Mr. A. P. TROTTER expressed the opinion that earthing of lead-covered cables should be carried out at definite places, viz., at the most negative points of the cable, assuming that a tramway was in the neighbourhood. If they adopted the policy of earthing at frequent intervals it was only tempting the current to get in at the other points. With regard to protecting cables from mechanical damage it seemed to be a growing practice among engineers to use a 2 in. creosoted plank in 12-ft. lengths, which could not be shifted by a navvy's pick.

Mr. VERNIER, in replying to the discussion, said that he had been told by Mr. Ferranti that some of the original cables from Deptford to London, put in 22 years ago, were still working. The method of bonding at the most negative points, as suggested by Mr. Trotter, was one which he utilised. The cables upon which his braided joint tests had been carried out were 0·1 sq. in. section, with 7,000 amperes per sq. in. on the conductor, but the joint, being larger, did not have this current density. In testing long lengths of cable of great capacity transformers of large size were required. The A.E.G. in testing their 20,000 volt cables had inserted a choking coil, for cutting down the capacity current, in parallel with the cores of the cable, but even then they had a large transformer. Another point was how were they going to get 200,000 volts D.C. readily. Faults from vibration were getting quite a serious matter, and on a small railway system with which he was acquainted they represented 20 per cent. of the whole. This was a solid system; on the other hand, with armoured cables he did not know of a case of faults having occurred through vibration. Mr. Howell had mentioned laying the solid system in 10 or 12-ft. lengths, but the usual practice nowadays was to open up a quarter of a mile at a time

ELECTRIC TRACTION ON THE BRIGHTON RAILWAY

A PAPER was read last week before the Institution of Civil Engineers by Mr. Philip Dawson, entitled "The Electrification of a Portion of the Suburban System of the London, Brighton and South Coast Railway."

In 1903 the Company obtained powers to electrify their line, and the author was called in to report on the question of experimentally adopting electric traction on the section between Victoria and London Bridge. The third-rail system was not considered suitable for general use on the railway, and in accordance with the report, single-phase alternating working, with overhead conductors at 6,700 volts at 25 cycles, was decided upon; tenders were called in 1905, the contract was let on March 30th, 1906, the first electric train ran on January 17th, 1909, and public service was inaugurated on December 1st, 1909. The trains accomplish the distance of 8·7 miles between London Bridge and Victoria, including ten stops of 20 seconds each, in 24 minutes. The results obtained were so satisfactory that the Company decided to extend the system from Battersea to the Crystal Palace and Selhurst, and from Peckham Rye via Tulse Hill to the Crystal Palace, bringing the total length of route electrified to 23 miles, or 62 miles of single track.

The minimum drop in the earth-return is limited by the Board of Trade to 20 volts, and the system of feeding was specially designed to meet these requirements, using series booster-transformers. Current is furnished by the London Electric Supply Corporation, from their power-station at Deptford, and delivered to the Railway Company at Queen's Road and Peckham Rye, where it is metered for payment.

The rolling stock comprises sixteen motor-coaches, each equipped with four 115-h.p. Winter-Eichberg compensated repulsion motors, and thirty-two trailer-cars, the trains being made up in units of two, three, or four coaches as required. The stock for the extension now nearing completion comprises thirty motor-coaches, each equipped with four 150-h.p. Winter-Eichberg motors, and sixty trailer-coaches, the train units being composed of two, three, four, six or nine coaches. Owing to the flexibility of the design employed, no trouble has been experienced with the overhead construction, and the extensions are being constructed to exactly the same design. The diameter of the trolley-wire is ½-inch, and it is supported by two catenary wires, by means of specially-designed insulators of a type not hitherto used for railway work. In the terminal stations the height of the conductor is 20 ft., but the normal working height is 16 ft., and the lowest position under certain bridges is 13 ft. 9 in. Double-insulation is used throughout, and the only insulation employed is porcelain. The overhead conductor has interfered very little with the signalling system.

The motors have four poles and are fitted with six sets of brushes. The air-gap is 3 millimetres and the synchronous speed is 750 r.p.m., although the motors are capable of developing torque at higher speeds. The gear-ratio is 4·24 to 1. The current taken per motor at starting on the low-tension side is 210 amperes, with a power factor of 29 per cent. Each motor-car is fitted with two main 220 kw. transformers, one for each pair of motors. None of the high-tension circuits on the car are accessible except when the collector-bows are lowered and when all the high-tension gear is earthed; the collector-bows are kept against the trolley-wire with springs which are brought into operation by means of a piston worked by compressed air. The contact-surface is aluminium and easily renewable, one contact-strip running 5,000 to 6,000 miles and taking practically all the wear; after thirteen months' running no appreciable wear can be measured on the trolley-wire. The pressure of the bow-strip against the trolley-wire varies between 8 and 12 lbs. The control of all the motors on the train is effected by means of contactors worked by master-controllers on the multiple-unit control system in every way similar to that in use with direct-current motors. Special repair-shops are provided at Peckham Rye, and are fitted with electrically-driven travelling cranes, machine-tools, capstans, &c., and all the motors, as well as the lights, are taken off the single-phase traction circuit.

The motors were tested at the maker's works on a complete equipment rigged up as for service conditions with an artificial load on the motor. As much as 180 h.p. was repeatedly thrown suddenly on and off without any tendency to flash over. The largest starting-torque measured was 255 kilogram-metres (1,847 pound-feet). Tests of the heating of the motors when run with open covers gave a temperature rise not exceeding 75° C. (167° F.) for the following loads :— 187 h.p. for 17 mins., 129 h.p. for 46 mins., 91 h.p. for 1 hr. 50 mins., or 57 h.p. continuously.

A three-car train consisting of two motors and one trailer, loaded up to a total weight of 146 tons, was run continuously for 12 hours with 20-second stops at each station as a trial, and covered in this time a distance of 173·58 miles, the average length of run being 0·79 miles. At the conclusion of this run the maximum rise of temperature of any part of the electrical equipment was 66° C. (151° F.). During this test the following results were obtained: power-factor, 80·8 per cent.; maximum current at starting, 126 amperes; average acceleration, from 0 to 25 miles per hour, 1·75 ft. per sec. per sec.; and the power consumption on the train 73 watt-hours per ton-mile. Subsequent tests gave in the case of a single trip from Victoria to London Bridge an energy-consumption of 65·7 watt-hours per ton-mile for a schedule speed of 22 miles per hour, including 20-second stops at each station, and for a through non-stop trip from Victoria to London Bridge at an average speed of 37 miles per hour, the energy consumption was 34·4 watt-hours per ton-mile; the maximum speed reached during the run being 50 miles per hour. The following are some of the weights of the various component parts of this train :—Complete motor-car on rails, 53·95 tons; one motor-bogie without motors, 7·51 tons; motor-coach body and under-frame without electric gear, 19·83 tons; total weight of all electric gear, including bows, wires, lighting, compressor, &c., for one motor-coach (four motors), 18·16 tons. For the four-motor equipments consisting of 150-h.p. motors for the extension, the total weight is only increased by 19 cwt.

The results obtained during actual running more than confirm the test results. The average energy-consumption for the first eight months of 1910 was 75·4 watt-hours per ton-mile, no allowance being made for weight of passengers carried, or for shunting or empty running, and including the energy used for light and power at the repair-shops. The efficiency between the high-tension bus-bars of the power-station and the trains was 96·6 per cent., and the efficiency of the system during controller notching was 67 per cent. The traffic results obtained have been as satisfactory as the technical results. The increase in passengers carried, as compared with those carried previously by steam, show that whilst for the first month's working the traffic had increased over 54 per cent., the month of December, 1910, showed an increase of over 125 per cent.

The first thirteen months' experience show no reason why the maintenance of single-phase should be higher than that for direct-current apparatus. The system is, in the opinion of the author, more economical than the direct-current system as regards energy-consumption at the power-station, as well as regards first cost, and experience has shown it to be

Hosted by Google

eminently suitable, not only for long-distance work, but also particularly for working in and out of large terminal stations with their necessarily complicated approaches, and for short-distance work.

The principal contractors were the Allgemeine Elektricitäts Gesellschaft, of Berlin; all the overhead work has been carried out by Messrs. R. W. Blackwell and Co., and the rolling stock was constructed by the Metropolitan Amalgamated Carriage and Waggon Co., of Saltley, Birmingham. Great credit is due to the contractors for the excellent way in which the work has been carried out.

ELECTRICALLY-DRIVEN FIRE-ESCAPES FOR LONDON

WITHIN the last few months three electrically-driven fire-escapes, for use at different stations of the London Fire Brigade, have been delivered to the London County Council by Cedes Electric Traction, Ltd. (15 Cockspur Street, London, W.C.). Previous to placing the order the Fire Brigade Committee carried out a long series of tests, extending over four months, on a chassis put at their disposal by Cedes Electric Traction, Ltd., and the results of these tests, and the satisfaction given by the two hundred or more similar vehicles in use on the Continent, have led the London County Council to give the vehicles a thorough trial in London service.

The construction of the vehicle is illustrated in Fig. 1. It consists of a chassis with battery, motors, and control

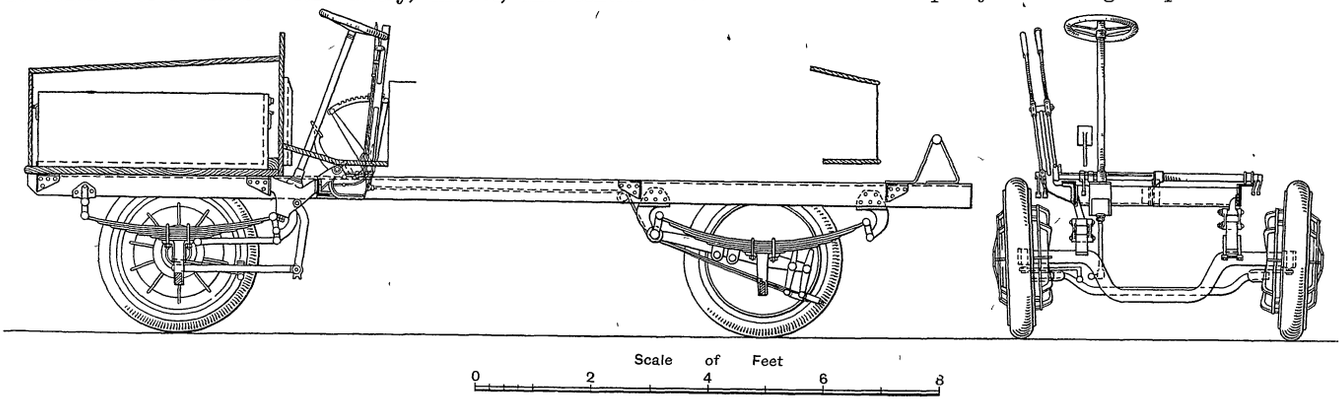

FIG. 1.—CHASSIS OF L.C.C. ELECTRICALLY-DRIVEN FIRE-ESCAPE.

equipment, a light body with the gear for holding the fire-escape, and a small pumping set, which is used previous to the arrival of the fire engines. The total weight, including the escape and a crew of five men, is 5 tons 5 cwt. The battery is of the Tudor Co.'s make, and comprises 84 cells of a total weight of 26 cwt., and giving 200 ampere-hours at the four-hour rate. Two hub motors of the well-known Mercedes pattern are provided, one in each of the front wheels. These motors are rated at 20 h.p. each, and are controlled by an ordinary traction controller on the usual series-parallel system. Electric braking can be effected by means of the motors on the front wheels, while the rear wheels are provided with band brakes. The motor wheels have solid rubber tyres, and each weighs 5 cwt. complete with motor. It will be remembered that the field system is in the shape of a star mounted on the stub axle, while the revolving armature surrounds this and is built into the wheel. The main leads are taken through the axle to the brush gear, which is fixed over a radial commutator. Ball bearings are provided. The speed of the motors is only 170 r.p.m. at the full speed of the vehicle, but an efficiency of over 80 per cent. on full load is obtained.

The Council specified that the fully-loaded vehicle should attain a speed of 25 miles per hour on the level. Tested on the embankment, a speed of over 26 miles per hour was reached. It was also specified that it should climb Pentonville Hill (1 in 24) at a speed of 15 miles per hour, and it accomplished it at 16 miles per hour. Finally, the vehicle had to perform a run of 25 miles out from Pentonville and back in one and a half hours on one charge, and this, of course, it did easily. One vehicle has already been run some 800 miles, and has repeatedly given 35 miles on one charge, while 40 miles is sometimes reached. One of the chief advantages of these electrically-driven vehicles is the fact that they are always ready for instant use. Thus, on the occasion of a certain call recently, when the men were timed, it was found that the men were in their places and the vehicle clear of the station in seven seconds from the instant when the alarm-bell rang. A charging plug and switchboard are provided in the station where the vehicle stands, and the cells connected up for charging directly the vehicle returns. On a call being given, the cells can be instantly disconnected from the plug and the vehicle is ready to leave. With regard to the life of the battery, it may be mentioned that the Tudor Co. supply a special plate for this severe traction work; we understand that the positive plates last 5,000 miles and the negative plates 10,000 miles.

THE G.B. SYSTEM IN THE MILE END ROAD

Successful Libel Action Appeal

IN the Appeal Court on Wednesday, before the Master of the Rolls and Lords Justices Fletcher-Moulton and Buckley, Sir John Benn appealed against the verdict of £12,000 awarded by a special jury in respect of certain statements made by him concerning the G.B. surface-contact system, which was laid down by the London County Council in the Mile End Road. We reported the details of the action before Mr. Justice Ridley, in ELECTRICAL ENGINEERING, Vol. VI., 1910, pp. 735, 743, 759, and 782. In the course of his political campaign, Sir John Benn made a number of speeches and wrote certain articles, in which he attacked the Moderate party for having adopted the G.B. surface-contact system in London, and at the same time referred to the system as an impossible one, which all competent tramway experts had declared unsuitable for London. He also referred to the system as the "live"-stud system, and used various other expressions. The jury disagreed as to whether there had been special damage in the way of a trade libel, but awarded £12,000, to be equally divided between Messrs. Griffiths and Bedell for personal libel.

Sir Edward Clark, in opening the appeal for Sir John Benn, said that the case to be considered by the Court was one of personal defamation, the jury having disagreed on the question of trade libel and special damages. The appeal was for judgment for Sir John Benn or a new trial by reason of the misdirection of the jury by Mr. Justice Ridley. He argued that from the beginning the action was one for trade libel, and that when the jury disagreed upon this point the question of personal libel should have been withdrawn from the jury by the judge. The onus was now upon Messrs. Griffiths & Bedell to show that the statements complained of were in the nature of personal libels. His contention was that all through Sir John Benn had attacked the G.B. system, and had not on any occasion cast any reflection upon Messrs. Griffiths and Bedell personally. Neither in examining his own witnesses, nor in cross-examining Sir John Benn, had Mr. F. E. Smith, who appears for Messrs. Griffiths and Bedell, put any questions relating to personal libel, and it was clear that the case did not fall within that category.

The appeal for judgment for Sir John Benn was taken first, as if this succeeded there would be no need for the case for a new trial to be gone into.

Mr. F. E. Smith, for Messrs. Griffiths and Bedell, argued that there were numerous statements in the libels which personally reflected upon Messrs. Griffiths and Bedell, and these undoubtedly brought the case within personal libel, although it had been made by way of an attack upon their business. Throughout his argument Mr. Smith found himself opposed frequently to the views of Lords Justices Fletcher-Moulton and Buckley. The former put it to Mr. Smith that Messrs. Griffiths

Hosted by Google

and Bedell had merely granted a licence to the London County Council to use their patents, and that they had not themselves laid down the tramways in the Mile End Road. He failed to see how it could be libellous upon the patentee to say that the licensee of the patents had failed to make them work. The most that could be said was that Messrs. Griffiths and Bedell had supplied certain parts, but after reading carefully through the libels he had come to the conclusion that there was no allegation of bad workmanship anywhere.

Mr. Smith pointed to statements such as "jerry-built tramways" and "live studs," but Lord Justice Fletcher-Moulton implied that as Messrs. Griffiths and Bedell did not supply the tramways in the Mile End Road, these statements could not be held to apply to them personally. As an attack upon the Moderate party of the London County Council, he thought a great deal could be said with regard to the libels.

Mr. Justice Buckley said it seemed to him that the proposition really was that the purchaser of the goods used them in a place where they were not suitable, and surely that was not libel. It certainly had been said by Sir John Benn that all competent experts had declared the system to be entirely unsuitable for London, but in order to make that a personal libel it would be necessary to have the further suggestion that Messrs. Griffiths and Bedell knew that the system would not work in London when they entered into the arrangement with the London County Council.

Mr. Smith disagreed with this, and said he had contended all through that the system in the Mile End Road was the G.B. system, and that Sir John Benn had intended to attack it as such. The effect was to charge Messrs. Griffiths and Bedell with being inexpert in their business.

On Monday the Master of the Rolls said that in his opinion the whole of the criticisms complained of had been directed against the system, and he could find no statements which, in his opinion, were personal defamations of Messrs. Griffiths and Bedell. It was extravagant to contend that an attack on a system was an attack on the patentees when these patentees had only supplied parts and granted a licence to someone else to use their system. In his opinion, therefore, the appeal must be allowed and judgment entered for defendants. Lords Justices Fletcher-Moulton and Buckley agreed.

In a discussion as to costs, the Master of the Rolls decided that, having regard to the peculiar circumstances of this case, the Court must give the strict order for judgment for Sir John Benn with costs in the Appeal Court and the King's Bench action. Mr. Smith indicated that the case would be carried to the House of Lords.

TURBO-ALTERNATORS WITH CYLINDRICAL ROTORS

IN a Paper read on March 8th before the Birmingham Section of the Institution of Electrical Engineers, Mr. S. P. Smith, of the General Electric Co., Witton, dealt with the characteristics of turbo-alternators with non-salient poles, giving special attention to the shape of the E.M.F. wave-form. The author points out that the general opinion is that a sine-wave is the best, and states that the non-salient pole machine closely approaches the ideal in this respect. Taking a rotor slotted uniformly over the whole periphery with equal-sized slots containing the same number of conductors, and a few slots in the middle of each pole left unwound, the ratio of the number of wound to the number of unwound slots may be called β. Formulæ are developed giving the harmonics which will be present in the M.M.F. curve for any value of β, and the results given in tabular form show that the more the winding is concentrated (*i.e.*, the lower the value of β), the greater is the amplitude of the fundamental curve, and consequently the higher the E.M.F. By concentrating the winding, therefore, the output is increased, or, conversely, fewer ampere-turns are required for a given output. Thus, taking the amount of copper required for a given output at 100 per cent. with $\beta=1$, the amount of copper for $\beta=0{\cdot}8$ is 84·5 per cent, 78·5 per cent for $\beta=0{\cdot}7$, and 74 per cent. only for $\beta=6$, which is the lowest value of β found in practice, owing to the difficulty of accommodating the winding in the slots.

Turning to the question of harmonics, the author points out that all harmonics above the 5th are negligible because of their small magnitude and low winding factors. The 3rd and 5th, however, may reach 10 and 5 per cent. respectively of the fundamental in the flux wave in passing from $\beta=0{\cdot}9$ to $0{\cdot}6$, but on account of the influence of the winding factors with distributed windings, the amplitude of the 5th harmonic in the E.M.F. wave is generally less than 1 per cent., and in a non-saturated machine can also be neglected. At $\beta=0{\cdot}66$, the 3rd harmonic is zero, but for other values this harmonic becomes appreciable, and may reach nearly 7 per cent. in the E.M.F. wave of a three-phase machine. In order, therefore, to obtain a sine-wave flux and E.M.F. curve, the value of β should be chosen between $0{\cdot}7$ and $0{\cdot}6$. The best distribution from all points of view is obtained with $\beta=0{\cdot}85$ to $0{\cdot}65$, as then there is plenty of space for the copper, and the heating is more distributed.

Considering the influence of saturation, Mr. Smith shows that this causes the flux curve to be rounded off, and tends to improve the shape of the wave. He then explains how the flux and E.M.F. waves can be constructed from the data of the machine, and works through an example of a 600-kw. four-pole 50-cycle alternator. He gives two alternative methods of calculating the open-circuit characteristic, and then proceeds to consider the effect of load upon the E.M.F. wave-form. The armature M.M.F. of a three-phase machine is distributed practically sinusoidally over the pole pitch when the load current follows a sine law, and by compounding this with the main M.M.F. at the proper phase displacement, the effects on the excitation and the E.M.F. wave can readily be deduced. In a salient pole machine, the flux and pressure curves are more or less skewed and distorted, but this does not occur in a non-salient pole machine, because both stator and rotor M.M.F. curves are practically sine curves; and as the reluctance of the magnetic path is constant for any position, the flux on load is simply the sum of these two curves at the proper phase displacement, and is therefore also a sine curve. The E.M.F. curve will also be a sine curve. It should be mentioned, however, that the constant reluctance of the magnetic path holds only for the uniformly slotted rotor with constant air-gap. Finally, Mr. Smith points out how the non-salient pole machine adapts itself readily to standardisation. For 50 cycles, machines up to 2,000 kw. are made two-pole for 3,000 r.p.m.; up to 5,000 kw., four-pole for 1,500 r.p.m.; and up to 5,000 kw., six-pole for 1,000 r.p.m. A very few diameters are chosen for each speed, and the outputs are varied by altering the core-length. The air-gap, teeth and cores are identical. The open-circuit characteristic will thus be the same for all machines of one diameter.

DISCUSSION.

Mr. A. M. TAYLOR (Birmingham Corporation), referring to some figures in the Paper, showing the increase of output rendered possible by letting the regulation go, inferred that it was desired to push the alternator with bad regulation, and said that the only advantage gained was that the ratio of the short circuit to the normal current was reduced. This minimised the risk of damage to the alternator itself, but in case of a heavy short the sub-station machinery might be thrown out of step.

Dr. KAHN (Brush Electrical Engineering Co.) saw no reason why alternators up to 3,000 k.v.a. should not be built to run at 3,000 r.p.m. The slots in the rotor should not be made too deep, so as to avoid excessive mechanical pressure on the insulation. It was important to make the best use of the copper space available on the rotor.

Mr. PENSABENE (Electric Construction Co.) complained that the author had taken no account of the effect of the slots and the fringing of the flux. He preferred the graphical method of building up the wave form, which was not a trapezium as stated by the author, but had ripples caused by the teeth. He did not consider that the distributed winding used in cylindrical rotors lent itself any more readily to standardisation than the salient pole type. There was no difficulty in the latter case in shaping the poles so as to produce a sinusoidal wave.

Mr. H. W. TAYLOR (British Thomson-Houston Co.) referred to the reduced excitation required with a concentrated winding, and asked whether the diminution in the excitation losses in a distributed winding due to the proportion between the coil inside the slot and the overhanging portion had been considered. He thought it was usual to leave no unwound slots in the rotor in order to avoid the saturation trouble. The tendency was to manufacture 50-cycle machines of only two speeds, and to build more of 3,000 r.p.m. than of 1,500 r.p.m. even for very large outputs. With reference to the effect of a short on sub-station machinery alluded to by Mr. A. M. Taylor, an alternator with poor regulation would stand the strain, and the sub-station machinery should also be designed with the same factor of safety. Rotaries were usually provided with reactances which limited the short-circuit current. If automatic voltage regulators were used, a machine of poor inherent regulation and, therefore, of low price could be used, and the cost of the regulator would be more than balanced by the decreased cost of the alternator.

Mr. SMITH, in reply, emphasised that the Paper treated the problem in general, and did not, therefore, include the effect of the teeth and different forms of slots. He denied having advocated the machine with bad regulation; he had simply pointed out that it was a cheaper machine, and discussed its characteristics. There was no difficulty in obtaining a true sine wave without the ripples referred to by Mr. Pensabene. The type of rotor in which the unwound portion of the circumference was left solid and not slotted was protected by a patent, and could not, therefore, be generally adopted.

REGENERATING OLD BATTERY PLATES

CONSIDERABLE success has attended the application of a new chemical process for the regeneration of old storage battery plates. A number of complete batteries, made up entirely from the negative plates of exhausted cells of different makes, have been proved to give, in some cases, even better results than the original batteries, while the cost of making up such a regenerated battery is less than half the cost of a new one. The process is the invention of Mr. E. H. Naylor, and is being worked by the Regenerating Battery Co. (3A Blenheim Street, Chelsea). The old negative plates, riddled with cracks between the active material and the grid, are dipped in a bath of certain chemicals, baked for a short time, and then reduced electrolytically to eliminate all impurities. This treatment has the effect of expanding the material so that it fills up all interstices and cracks. The treated plate is more uniform, of higher conductivity, and, as the material has expanded, is more porous than before the treatment. Furthermore, the material is much harder than that of a new plate, and is claimed to retain this hardness after formation. A complete battery is made up from the negative plates of two old ones, one of the outer of each set of plates which is to be positive being cut off, so that both outside plates are negative. It is stated that apart from the saving effected by the regeneration of exhausted plates, the regenerated batteries have a longer life and an efficiency 10 to 15 per cent. higher than the original batteries, and at least equal capacity.

By the courtesy of the Krieger Electric Carriage Syndicate, Ltd., we are enabled to publish the results of their experience with batteries regenerated as above from some of their scrap negative sections. The cells used by this company are of the French Chloride pattern, and are purchased from the Société Anon. pour le Travail Electrique des Métaux. They have an average life of from 3,000 to 3,500 miles, and generally require washing after three months' use, corresponding to about a thousand miles' run. Twenty complete regenerated batteries, each of 44 to 46 cells of 15 or 21 plates each, have already been made up from the company's old batteries, and the following are some of the results obtained: No. 1 battery of 46 cells, each with 21 plates and weighing 30 lbs. with electrolyte, put in service in April of last year, had given, when it was scrapped in January last, a total mileage of 4,500, or 1,000 miles more than the average figure for the new batteries. During that period the cells were washed out three times only, the hardness of the regenerated material apparently reducing the amount of deposit. Only half the cells were actually scrapped; the others are in use in other cars replacing damaged cells. Further, some of the negative plates of the scraped regenerated cells have been regenerated a second time. This particular battery did 47 to 48 miles on one charge, and that in the bad weather. The maximum capacity of the cells has been from 170 to 180 ampere-hours—if anything, slightly higher than the capacity of new cells. No. 2 battery, put in service in August, 1910, has run 2,960 miles up to date, but has required three washings, due to a slight accident; No. 3, put in in September, has run 3,480 miles up to date with only two washings; No. 4 (October) has run 2,730 miles with one washing only; No. 5 (November), 2,740 miles with two washings; and No. 6 (December), 1,560 miles with one washing. The other batteries put in since are behaving satisfactorily. Mr. F. S. Coles, works manager of the Krieger Co., is most enthusiastic about the new process, and expressed himself highly satisfied with the results. He said that the only respect in which the regenerated batteries did not equal new batteries was the larger number of charges and discharges before they reached their full capacity. Mr. Coles receives the plates unformed, and tells us that they appear to stand storage well, showing no signs of sulphating. He considers that the process will materially assist in popularising electric vehicles of all kinds for town and suburban use for a range within fifty miles.

The Regenerating Battery Co. have already delivered over thirty regenerated batteries to different electric carriage companies, and are now beginning to deal with train-lighting batteries. Ignition batteries are, of course, easily dealt with, but large station batteries are more difficult to handle. Practically any make of cell can be regenerated, and among those already dealt with are E.P.S., Tudor, and Hart cells, but the results naturally depend a good deal on the original quality of the cell when new.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

ELECTRICAL THERMOMETERS.—We have received a pamphlet on electrical distance thermometers from the Leskale Co. (Palace Works, Enfield). The Leskale instrument when used for temperatures up to 900° F. is a resistance thermometer employing pure nickel wire. The resistance is measured on a galvanometer by comparison with standards in the arms of a bridge arrangement. The resistances are adjusted so that the pointer remains at rest when the thermometer element has the desired starting temperature of the scale, but moves as soon as the temperature rises, indicating it direct in degrees. The indicating instrument and all necessary switches, &c., are mounted conveniently on a marble panel. Current is supplied from a single secondary cell. For higher temperatures, outfits on the thermo-electric principle are employed, using iron-constantan up to 1,000° F., a carbon-nickel combination up to 2,300° F., while for the highest temperatures platinum and platinum-rhodium are made use of. A copy of a test certificate from the National Physical Laboratory accompanies the pamphlet.

ELECTRIC FURNACES.—A leaflet from Messrs. Verdon, Cutts & Hoult gives a drawing of their "Electro-Bessemer" furnace for the production of high grades of steel, in which the conversion is first effected by the ordinary Bessemer process, and the subsequent refining is carried out electrically in the same vessel without any pouring being required.

THREE-PHASE MOTORS.—The Sandycroft Foundry, Ltd. (near Chester), have sent us a copy of a reprint of a Paper by Mr. Williams-Ellis, describing Mr. L. J. Hunt's "cascade" induction motor, which is manufactured by the firm, read at a meeting of the Association of Mining Electrical Engineers last summer.

DRAWING AND SURVEYING INSTRUMENTS.—A supplement to the instrument catalogue of Messrs. A. G. Thornton, Ltd., deals with a new gradient measure and several novelties in pens and drawing office accessories. A separate leaflet describes an entirely new system of adjustment for spring bows.

OSRAM LAMPS AND FANCY DRESS

AT a recent fancy dress rinking carnival, held in Carnarvon, where prizes were offered for the most original costumes bearing on present-day street posters, Mr. J. T. Rees was successful in securing an award for his representation of Electric Light, the attractions of which he chose to demonstrate by means of Osram lamps, which he had secured to various parts of his suit of overalls, and each of which was controlled by a

Osram Lamp Costume.

switch, the current being obtained by means of a 4-volt accumulator. In addition, as will be seen by the above illustration, the successful competitor displayed on his costume examples of various Osram advertisements, using for his helmet the popular Osram lamp shade, illuminated from within by means of an Osram battery lamp. We are informed by the General Electric Co. that this is the tenth instance during recent weeks in which competitors at fancy dress carnivals have secured awards by representing Osram lamps.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published March 16th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.
Names in italics indicate communicators of inventions from abroad.

8,913/10. **Lamp Lock.** W. P. COLLINS (Dublin). A ring screwed down on the top portion of a standard lamp-holder by means of a special key, presses the brass cap down on to the porcelain contact holder and prevents the lamp being pushed upwards to free the pins. Three figures.

13,295/10. **Leading-in Wires.** BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*). A short length of drawn ductile tungsten or molybdenum wire is used as a leading-in conductor for incandescent lamps. The wire is dipped into fused potassium nitrite before sealing it into the glass, as it is necessary that it should be free from dirt and oxide.

Opposition to Grant of Patent

27,380/09. **Recording Instruments.** H. HAMMARLUND. This patent has been allowed in spite of opposition. The specification was abstracted in ELECTRICAL ENGINEERING, October 20th, 1910, Vol. VI., p. 666.

Amendments

19,626/06. **Textile Machinery.** BROWN, BOVERI & Co., LTD., desire to insert the following words (in italics) in the first claim of this patent, which will then read as follows:—"In an electrically driven ring spinning machine, automatically altering the number of revolutions *of the machine shaft to give a high main and lower initial and finishing speeds* by a regulating apparatus of the motor controlled from one of those parts of the spinning machine adapted to regulate the movement of the ring rail." It is also desired to correct the drawings.

7,612/08. **Textile Machinery.** BROWN, BOVERI & Co., LTD., desire to correct a figure, and to amend the claim of this patent, which will read thus:—"An electrically driven ring spinning machine wherein the number of revolutions is automatically varied with varying diameters of the bobbin or cop, as already known, and wherein the number of revolutions for equal diameters is diminished towards the end of the spinning period, in relation to the number of revolutions during the main portion of the spinning period, *whereby increased production is obtained.*"

24,643/08. **Storage Battery Plant.** A. M. TAYLOR. This specification has been amended as detailed in the Official Journal of the Patent Office of March 15th, 1911. The specification was abstracted in ELECTRICAL ENGINEERING, October 20th, 1910, Vol. VI., p. 666.

27,478/09. **Electrical Marine Propulsion.** H. A. MAVOR and MAVOR & COULSON, LTD. As a result of the extended investigation under Section 8 of the Patents Act, a disclaiming note has been inserted in this specification. The patent (abstracted in ELECTRICAL ENGINEERING, Nov. 10th, 1910, Vol. VI., p. 718) covers an alternator for generating at two different frequencies without any change in speed.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.
Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: JANDUS ARC LAMP & ELECTRIC Co., JONES and CASTELL-EVANS, 5,965/10; RIDINGS, 13,535/10; AUGUST SCHWARZ [Double-carbon lamp] 16,841/10.

Distributing Systems, Cables & Wires, Insulating Materials, &c.: MURDOCH (*Robinson*) [Connecting wires to insulators] 5,383/10; HOFLE [Manufacture of insulating tubes] 25,555/10.

Dynamos, Motors, and Transformers: HOLLICK [Control of electrically-driven winding gear and hoists] 10,245/10; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Motor control] 12,265/10; SIEMENS BROS. DYNAMO WORKS (*Siemens-Schuckertwerke Ges.*) [Speed regulation of polyphase motors] 25,964/10; KULKA [Oil-cooled transformers] 2,241/11.

Electrometallurgy and Electrochemistry: PRESSER [Electric welding] 15,031/10, and [Electric welding with continuous current] 15,032/10; GIBBS [Electrolytic manufacture of wire] 19,593/10; CONSIGLIERE [Electro-deposition] 20,776/10.

Heating and Cooking: ELY and FOSTER ARC LAMP & ENGINEERING Co. [Water heaters] 6,065/10; HAWKES [Heating and cooking apparatus] 19,466/10.

Incandescent Lamps: LEDERER and WESTINGHOUSE METAL FILAMENT LAMP Co. [Manufacture of metal filaments] 5,388/10.

Instruments and Meters: ROBISON and JONES [Recording apparatus] 27,904/09; DRYSDALE [Electrical dynamometer] 4,669/10; GODDARD [Prepayment meters] 7,587/10; BURROWES [Electrostatic voltmeter] 10,722/10.

Storage Batteries: HEAP, 2,062/10; SCHMIDT [Charging systems] 22,888/10.

Switchgear, Fuses, and Fittings: TURNER and FENWICK [Contacts for contact-breakers] 30,101/09; BAKER and LONGSTRETH'S, LTD. [Lamp-holders] 11,275/10; LAKE (*Crawford*) [Machines for running fish wires through conduits] 17,165/10; WEISSMANN [Lamp-holders] 18,738/10; BROUGHAM (*Moore Electrical Co.*) [Vacuum tube lighting apparatus] 20,661/10; FAIRWEATHER (*Stein*) [Switch] 22,412/10; SOC. ANON. "PHI" [Commutator switch] 24,851/10.

Telephony and Telegraphy: VON LEPEL and BURSTYN [Oscillation generator] 30,030/09; FESSENDEN [Wireless telegraphy] 5,133/10; MURDOCH (*Robinson*) [Connecting wires to insulators] 5,383/10; SIEMENS BROS. & Co. (*Siemens & Halske A.-G.*) [Automatic telephone exchanges] 6,654/10; GOLDSTEIN [Central battery signalling systems] 16,336/10; VON KRAMER [Inductive wireless telephony] 21,451/10.

Traction: ROSENGREN [Automatic pipe couplings] 5,381/10; BATCHELDER [Electrically-driven vehicles] 8,363/10; CROSS (*Krizik*) [Electrically-actuated brakes] 17,597/10; SIEMENS BROS. & Co. and FERRIERA [Signalling on single lines] 24,158/10; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Rail bonds] 30,138/10.

Miscellaneous: ADAIR [Conveyors] 19,642/09; JORDAN [Electric device for branding meat] 4,858/10; LICHTENFELD [Alarm] 5,385/10; BRITISH THOMSON-HOUSTON Co. (*Allgemeine Elektricitats Ges.*) [Regulating valves] 6,791/10; BICHEL [Submarine mines] 19,268/10; VICKERS, SONS & MAXIM, LTD. (*Elia*) [Submarine mines] 21,933/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Arc Lamps: KÖRTING & MATHIESEN A.-G. [Enclosed arc lamps] 3,891/11.

Distribution Systems, &c.: ALLGEMEINE ELEKTRICITÄTS GES. [Suspension of conductors] 4,623/11.

Dynamos, &c.: A.-G. BROWN, BOVERI ET CIE [Compounding of commutator machines] 4,256/11; HEYLAND [Starting and regulating A.-C. motors] 4,627/11.

Telegraphy: CEREBOTANI [Wireless operated signalling apparatus] 16,360/10.

Traction: COMPAGNIE DE SIGNAUX ELECTRIQUES POUR CHEMINS DE FER [Warning apparatus for signalling systems] 3,978/11.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

8,180 of March 30th, 1897. **Printing Telegraphs.** W. L. WISE (*C. L. Buckingham, U.S.A.*). This patent covers a printing apparatus for receiving and reproducing in page form telegraphic messages which have been transmitted at a high speed by a Wheatstone or other transmitter. The sheet of paper is placed on a cylinder in the form of a tube, and the chief claims of the patent cover mechanism to produce a positive rotary and axial feed of the paper tube.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Vapour lamps and rectifiers] 24,856/05.

Distribution Systems, &c.: BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Insulation of conductors with nitrocellulose] 26,456/03.

Dynamos, &c.: H. LEITNER and R. N. LUCAS [Train-lighting dynamo] 26,764/02, and [Train-lighting system] 26,082/04; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Armature windings] 26,171/04; A. F. HILLS, D. URQUHART and A. E. HONEY [Use of armature binding wires as equaliser rings] 24,877/05.

Instruments, &c.: A. WRIGHT and MUTUAL ELECTRIC TRUST [Maximum demand indicator] 24,126/99; W. CHADBURN [Speed indicator] 21,328/00; C. W. ATKINSON [Maximum demand indicator] 26,267/03.

Switchgear, &c.: A. HEPKE and K. DIENER [Multiple fuse plug] 26,180/03; VICKERS, SONS, & MAXIM, A. D. WILLIAMSON, and C. L. SUMPTER [Control of variable speed motors] 26,288/04; W. ANDERSON [Lamp globe gallery] 24,475/05; C. W. ATKINSON [Motor controller] 24,729/05.

Telephony, &c.: G. M. HARDINGHAM (*Felten & Guilleaume*) [Cores of submarine gutta percha-insulated cables] 25,095/98.

Traction: P. HALLOT [Automatic brakes] 25,837/03; W. GRIFFITHS and B. H. BEDELL [Resistance studs for surface-contact system] 25,969-70/03; J. S. and A. B. RAWORTH [Control systems for shunt motor equipments] 24,810/05.

Miscellaneous: E. LYTTON [Scenery raising gear] 24,261/01; H. C. HEIDE (*R. S. Baldwin, U.S.A.*) [Electrically operated monotype machines] 24,489/05; J. CARTER [Burglar alarm] 24,630/05.

Hosted by Google

LOCAL NOTES

Birmingham: *Tramways.*—The conversion of the cable tramway from Colmore Row to Hockley Brook to electric traction is in hand. The line will revert to the Corporation on June 30th, and arrangements are being made for running electric cars over the route on July 1st.

Carlisle: *Apprentices at Electricity Works.*—Commencing with the new financial year, the Electricity Committee recommend that apprentices shall be admitted in the Electricity Works. The number employed at the works at any one time is not to exceed six.

Dover: *Sunday Trams.*—A poll of the ratepayers has been taken, with the result that there is a majority of 1,164 in favour of running tramcars on Sundays.

Elland: *Proposed Tramways.*—The proposal that the National Electric Construction Co. should construct tramways between Halifax and Huddersfield, the Elland, Greetland, and Brighouse Town Councils borrowing the necessary money, and the company paying the capital charges, has fallen through.

Ireland: *Railway Electrification.*—At the recent half-yearly meeting of the Dublin & South Western Railway Co. a shareholder suggested that in order to improve the traffic the line should be converted to electric traction. The suggestion has been developed in some quarters, and the further proposition made that in order to reduce the cost of the conversion, power should be taken from the Dublin United Tramways Co. *The Financial Times* points out that the London & North Western Railway Co. is largely interested in the Dublin & South Western Railway Co., and in view of the construction of the Watford-Edgware electric railway by the London & North Western Railway Co., and the appointment of an electrical engineer in the person of Mr. Cortez Leigh, any suggestions regarding electric traction should receive careful, not to say expert, consideration.

Liverpool: *Tramway Accounts.*—The tramway accounts for 1910 show a gross profit of £209,252, and after meeting capital charges and placing £65,510 to reserve, renewals, and depreciation, a sum of £32,755 is transferred to relief of rates. The latter sum is about £5,000 in excess of the amount handed over in the previous year. The number of passengers carried was 125,507,283, an increase of 3,974,343 over the previous twelve months.

London: *County Council: Victoria Embankment Lighting.*—The Highways Committee recommend the use of Beck flame arc lamps on the Victoria Embankment.

Hackney: Electricity Accounts.—It is estimated that the net profit on the electricity undertaking for the year to March 31st will amount to £8,791, and the Finance Committee, in view of the substantial amount standing to the credit of reserve fund, recommend that a sum of £4,702, equal to a 1d. rate, be transferred to relief of rates.

Marylebone: Assessment of Electricity Works.—The dispute between the London County Council and the Marylebone Electricity Committee, in regard to the assessment of the electricity works, has been settled by an agreement to fix the assessment at £32,000. This is about £8,500 more than has been paid up to the present.

Manchester: *Tramway Employees.*—Sir David Harrel, K.C.B., has been appointed by the Board of Trade to sit as arbitrator in connection with the differences between the Tramways Committee and their employees.

Scarborough: *Tramways.*—It is stated that the Scarborough Tramways Co. have decided to resume the running of the trams next month, and to run them continuously during the following winter. The Corporation, however, have applied to the Board of Trade for an order revoking the company's powers, owing to their not having run a service during the past winter. Speaking at the meeting of the Scarborough Electric Supply Co. last week, Mr. A. A. Campbell Swinton expressed the hope that the Corporation would not persist in their attitude, as the Supply Company had erected a special plant to deal with the tramway load, and the complete cessation of the tramways would be a severe loss.

Torquay: *Tramways.*—The whole of the Dolter system has now been converted to the overhead trolley system, and the cars are running.

Walker: *Electricity Supply.*—The Newcastle Corporation having incorporated Walker within their district, have thought it advisable to purchase the rights which the Newcastle Electric Supply Co. have of supplying electrical energy for the tramways in that district. Sir Alexander Kennedy is sitting as arbitrator in London to determine the price.

Woodbridge: *Electric Lighting.*—Mr. Charrington, of London, has been asked to meet the Council to explain a scheme of electric lighting.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Australia.—The Deputy Postmaster-General, Melbourne, invites tenders by July 25th for 12 sections of a branching multiple magneto lamp-signalling switchboard, or alternatively an automatic or semi-automatic switchboard. The *Board of Trade Journal*, in giving this information, points out that the time available will only enable those firms having agents in Australia to tender.

Fiji.— The *Royal Gazette* for November 4th, says the *Board of Trade Journal*, contains the conditions under which a concession will be granted for 25 years for the supply of electrical energy and the working of an electric tramway in the town of Suva. The *Gazette* may be seen at 73 Victoria Street, London, S.W.

Glasgow.—The Electricity Committee require tenders by April 24th for a steam turbo-alternator with condensing plant.

Hastings.—The Local Government Board have sanctioned the borrowing of £2,083 for electric lighting.

London: *Bermondsey.*—The Electrical Engineer recommends additional generating plant at an estimated cost of £20,100.

Hammersmith.—Tenders are invited by March 29th for high- and low-tension switchgear and static transformers.

Merthyr Tydfil.—The Merthyr Electric Traction Co. have entered into an agreement to extend their system to Cefn.

Rawtenstall.—A 500-kw. three-phase steam alternator and a 250-kw. motor generator are required. Tenders by March 31st, and particulars from the Borough Electrical Engineer.

Roumania.—*The Board of Trade Journal*, quoting from a report by the German Vice-Consul at Craiova, states that there is a good market for electric generating stations in Roumania, as there is an increasing desire on the part of even the smaller towns to have electric lighting.

Torquay.—Tenders are invited for a turbo-generator, condensing plant and switchgear, motor generator and switchgear, and an electrically driven feed pump. (See an advertisement on another page.)

Watford.—A new high-tension feeder is to be laid at an estimated cost of £560.

WIRING

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings.

GREATER LONDON.

Drill Hall, Mitcham Road. Architects, Jarvis & Richards, 10 Queen Anne's Gate, Westminster.

PROVINCES.

Barnsley.—Proposed new Town Hall.

Birmingham.—Extension to Vittoria Street School for Jewellers and Silversmiths. Architects, Messrs. Cossins, Peacock & Bewlay, 83 Colmore Row.

Burnley.—Buildings on site of old barracks. Architect, W. Greenwood, Victoria Chambers, Blackburn.

Chatham.—County School, Chatham Hall. Kent County Education Committee.

Cleckheaton.—Cinematograph Theatre, Albion Street. Messrs. Howorth & Howorth, Old Bank Chambers.

Dover.—A contract has been let to a local firm for the building of an electric theatre.

Dudley.—New school to accommodate 400 scholars.

Glasgow.—Two new Roman Catholic Schools.—Music Hall and Theatre of Varieties.

Keighley.—Alterations to St. Ann's Schools. Rev. J. F. Russell.

OSRAM·LAMPS

Hosted by Google

Leeds.—Two hostels for women students at City of Leeds Training College, Beckitt's Park. Architect, A. E. Kirk, Albion Street.

Lincoln.—Extensions to Lincoln County Hospital.

Middlesbrough.—Assembly Hall and Sunday Schools, Cemetery Road. Architect, James Forbes, 43 Albert Road.

Motherwell.—Primitive Methodist Church at corner of Avon and Clyde Streets.

Paisley.—Six four-story tenements in Seedhill Road.

Pontypridd.—New Infirmary.

Salford.—Electric lighting of Annexe at Town Hall. Borough Electrical Engineer.

Swansea.—Additions to premises at corner of Oxford Street and Waterloo Street. W. Edwards.

Wakefield.—Extensions to County Hall.

Woking.—Alterations to Head Post Office. H.M. Office of Works.

MISCELLANEOUS

Ashton-under-Lyne.—The Electrical Engineer has drafted a scheme for street electric lighting.

Dublin.—The Local Government Board is to be asked to sanction a loan of £3,000 for the purpose of lighting all the streets by electricity in which electric mains are laid.

Leeds.—The Tramways Committee invite tenders by March 31st for 25 electric tramcar trucks and 10 electric tramcar equipments. Particulars from the General Manager.

London: *County Council.*—The Highways Committee recommend the building of a third section to the Central Car Depôt at an estimated cost of £277,335.

Lancashire & Yorkshire Railway Co.—Tenders are invited for various stores, including electrical fittings, wires, &c. Particulars from the Stores Department, Osborn Street, Manchester, and tenders by April 3rd.

Wigan.—The Tramways Committee invite tenders for overhead line material, tramcar accessories, &c. Particulars from the Engineer, and tenders by March 27th.

TENDERS RECEIVED AND ACCEPTED

Aberdeen.—The Electricity Committee recommend the acceptance of a tender by Messrs. Willans & Robinson, Ltd., for a 1,000-kw. continuous-current turbo generator at £4,726. This set will take the place of two small generating sets.

Gloucester.—Messrs. Venner & Co. have received an order to supply tramcar meters on trial.

Colchester.—Messrs. Venner & Co.'s tenders for prepayment and ordinary meters have been accepted.

Dublin.—The Electricity Supply Committee recommend the acceptance of tenders by Messrs. Babcock & Wilcox, Ltd., for boilers, and the Maschinenfabrik Oerlikon for extensions to the Pigeon House Fort generating station. The total amount of the two contracts is £34,698. Although tenders were invited from thirteen firms, as a result of the short time allowed for installing the plant, namely, about six months, only three firms sent in complete tenders. The plant of the Maschinenfabrik Oerlikon has a guaranteed steam consumption of 15·95 lbs. per kilowatt hour, against 17·26 by Messrs. Willans & Robinson, 17·77 by Messrs. C. A. Parsons & Co., and 18·25 by the General Electric Co. The prices of the three latter were £11,809, £11,178, and £11,817 respectively. The accepted tender for generating machinery amounts to £11,458.

Hendon.—The Rural District Council have entered into an agreement with the North Metropolitan Electric Power Supply Co. to light the Edgware district by electricity.

Edinburgh.—The tender of the Motherwell Bridge Co. for the erection of cooling towers at the Dewar Place Electric Lighting Station is recommended for acceptance at £18,000.

Ireland.—Messrs. Francis Carr & Co., of Belfast, have received the contract for an electric lighting plant for Dungiven (Co. Derry). The dynamo will be driven by water turbines.

London: *County Council.*—The tender of Messrs. W. T. Henley's Telegraph Works Co., Ltd., at £136 11s., for laying 700 yards of feeder cable in Blackwall Tunnel, is recommended for acceptance.

Battersea.—The tender of the Sloan Electrical Co., Ltd., has been accepted for the supply of arc lamp carbons during the coming year.

Hammersmith.—The tender of the General Electric Co., Ltd., for the supply of Osram lamps for the year ending March 31st, 1912, has been accepted, after very severe competition.

Vancouver.—Amongst a number of colonial contracts just secured by the D.P. Battery Co., Ltd., is a 240-volt central station set with auxiliary plant for Vancouver.

Wycombe.—A contract has been entered into with the Wycombe (Borough) Electric Light & Power Co., Ltd., for street lighting for seven years.

Messrs. Mirrlees, Bickerton & Day, Ltd., have sent us a list of orders which they have recently received for Diesel engines varying from 50 h.p. to 500 h.p., and we select a few of the most important:—One 375-h.p. engine and one 500-h.p. engine for the London, Brighton & South Coast Railway Co.; two 150-h.p. engines for the Sale U.D.C.; one 375-h.p. engine for the Manekji Petit Mills, Bombay; one 200-h.p. engine for New Zealand; two 200-h.p. and one 132-h.p. engines for Canada; three 200-h.p. engines for Madeira; two 200-h.p. engines for the Barbadoes; and one 200-h.p. for Bulgaria.

APPOINTMENTS AND PERSONAL NOTES

A Clerk of Works is required in connection with the electrical installation at Richmond (Dublin) District Asylum. Applications to W. J. Murphy at Asylum Offices, Dublin.

Mr. L. S. Payne has left the Thorpe Meter Syndicate to take up a better position in the Testing Department with Messrs. Chamberlain & Hookham, Ltd.

Mr. P. G. Campling, Works Superintendent and Senior Charge Engineer at the Weymouth Corporation Electricity Works, has been appointed third engineer at the Bermondsey Electricity Works.

Mr. H. Parker, of the Gillingham Electricity Works, has been appointed Shift Engineer at the Dover Electricity Works.

Mr. E. W. L. Nicol and Mr. O. A. Pilcher have resigned their positions as Charge Engineers at the London County Council Greenwich Power House. Applications are to be invited for successors, at a salary of £250, rising to £300 per annum.

Mr. J. Glynn Williams, late of the Moresby Coal Co., whose name is well known in connection with the Association of Mining Electrical Engineers, has joined the staff of the Electrical Trades' Supply, Ltd., Britannia Works, Gt. Charles Street, Birmingham, as mining representative.

The salary of Mr. S. T. Allen, City Electrical Engineer at Carlisle, has been increased by £50 per annum, in addition to his usual increments of £20. The salary of Mr. J. H. Thompson, Chief Assistant Electrical Engineer, has been increased from £145 to £170 per annum. Mr. A. W. Barham, at present Charge Engineer, has been appointed Station Superintendent at a salary of £120 per annum.

The salary of Mr. C. G. Simpson, Traffic Superintendent to the Southampton Corporation Tramways, has been increased from £200 to £220 per annum, rising by annual increments of £10 to £250 per annum.

Obituary.—We regret to announce the death of Lord Airedale, which occurred in Paris on Thursday. Lord Airedale is better known to our readers as Sir James Kitson, whose name is familiar in the electrical industry in connection with the famous "Kitson clause" in electrical power Bills. Lord Airedale also presided, when a member of the House of Commons, over the committee which dealt with Mr. C. H. Merz's last power Bill for London, which, after being passed by a House of Lords Committee, was reported for third reading in the House of Commons by Sir James Kitson's Committee, but failed to become law owing to there being no time for the third reading to take place.

We also regret to have to record the death of Mr. M. B. Cotterell, of Veritys, Ltd., which occurred last week at his residence, "Waverly," Victoria Park, Manchester. Mr. Cotterell, who was only 41 years of age, died of double pneumonia, after three weeks' illness. We understand that he joined the firm as a pupil twenty years ago, when it was known as P. Verity & Sons, and dealt only with installation work. He became manager of the works, and later managed the business of the firm in the Northern districts, eventually obtaining a seat on the Board.

Telegraph Traffic.—The cable between Madagascar and Réunion was restored on the 16th inst., and on the following day the Réunion-Mauritius cable was also in working order.—The German Company announces reductions of 75 and 78 centimes on rates on the opening of their South American cable for traffic, and the Western Telegraph Co. has followed suit.—On the 18th inst. communication was broken between Villa Bocage and Chilomo in Mozambique.—On the 21st inst. communication between Lourenzo Marques and Bella Vista was down.—The Compagnie Française des Cables Télégraphique has not yet restored its connection to Brazil.

The Care and Management of Ignition Accumulators.—In the last line of the review of this book, published in our Literary Supplement last week, the words "8 volt" should read "10 volt." We are indebted for this correction to the author of the book.

Hosted by Google

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £57 to £57 10s. per ton (last week the same).

Canadian Agencies.—A London firm manufacturing high-class electric light fittings, is desirous of getting into touch with Canadian importers. Particulars from 17 Victoria Street, London, S.W.

An Ottawa correspondent who is at present in London is desirous of getting into touch with United Kingdom manufacturers of electrical generators and motors, lamps, instruments, small transformers, &c., requiring Canadian representation. Further particulars may be obtained at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., on March 14th, 1911.

Change of Address.—Messrs. Balcke & Co., Ltd., notify their removal to larger offices at Broadway Court, Broadway, Westminster; telephone, Victoria 1387.

Bankruptcies.—The last day for receiving proofs in the bankruptcy of J. A. Bauer, trading as the Electrical & General Engineering Co., 17 Gracechurch Street, London, is March 29th. Mr. G. E. Corfield, 19 Finsbury Pavement, London, is trustee.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

County of Durham Electrical Power Distribution Co.—There was a net profit of £15,532 for 1910, and after paying 3¾ per cent. on the preference shares and transferring £6,000 to depreciation and reserve, a balance of £157 is carried forward.

City of London Electric Lighting Co.—It was stated at the annual meeting on Friday that the number of consumers increased in 1910 by 538. The experimental street lighting demonstration in Farringdon Street, Watling Street, Paternoster Row, and Cheapside was still awaiting the judgment of a Special Committee of the City of London Corporation. Mr. J. B. Braithwaite, who presided, also stated that if the results for 1911 were satisfactory, the directors would probably feel justified in increasing the dividend, as the equalisation of dividend fund now stood at £14,000.

Fife Tramway, Light & Power Co.—In view of the fact that this company is promoting a Provisional Order for electric lighting in an extensive area in the county of Fife, and also in anticipation of a considerable extension in the amount of power required for the tramways, the directors recommend an increase in the share capital of £300,000. Last year, after meeting the 6 per cent. preference dividend, a sum of £3,590 was carried forward

Waste Heat & Gas Electrical Generating Stations.—At the annual general meeting last week it was stated that negotiations are proceeding for the erection of further generating stations; one utilising exhaust steam from the Port Clarence Ironworks of Messrs. Bell Bros., Ltd., and the other for the utilisation of exhaust steam from the Lackenby Ironworks of the Tees Furnace Co., Ltd. Arrangements have been made with the Cleveland Power Co., in whose districts these generating stations will be, under which the company will receive a regular and remunerative return for their use. Negotiations for a third generating station are also in progress. A further issue of capital is to be made during the current year in connection with these new stations. As already announced, a dividend of 8 per cent. was paid for 1910.

New Zealand.—The Christchurch Tramway Board are issuing £61,400 4½ per cent. debentures at 103. Applications for stock should be made to the Union Bank of Australia, London.

Rhondda Tramways Co.—The Law Debenture Corporation have offered, on behalf of the International Financial Society, £200,000 5 per cent. debentures of the Rhondda Tramways Co. at 94.

Metropolitan Electric Supply Co.—At the annual meeting last week, Mr. W. H. Cripps, who presided, stated that the company's new system for supplying electrical energy to their West Middlesex area was now partly completed, the trunk mains having been laid from Willesden to sub-stations in Hanwell and Southall.

Newcastle-upon-Tyne Electric Supply Co.—The connections to this company's systems on December 31st, 1910, amounted to 139,776 h.p., an increase of 10,557. After meeting debenture and loan interest, there is an available balance of £78,925, and a 4 per cent. dividend on the ordinary shares is recommended, transferring £15,000 to depreciation, and carrying forward £2,050. The general depreciation account now stands at £115,000.

Underground Electric Railways Co. of London.—At the meeting on Wednesday last week, Sir Edgar Speyer, referring to the dispute between the company and the British Westinghouse Co. with regard to the substitution of Parsons turbines for Westinghouse machines (see ELECTRICAL ENGINEERING. January 19th, p. 32), stated that Sir Alfred Lyttelton has now issued his award. The arbitrator has decided that the British Westinghouse Co. cannot claim the balance of the purchase money of the Westinghouse machines amounting to £83,000, which was retained by the railway company as a set-off against the cost of installing the Parsons turbines. In addition, the railway company have been awarded £15,000 damages as well as costs of the arbitration. It is also stated that the British Westinghouse Co. propose to contest the award.

Brompton & Kensington Electricity Supply Co.—Mr. H. R. Beeton, who presided at the annual general meeting last week, referred to the satisfactory results which have attended the opening of the company's showrooms. The contract system of supplying electricity for lighting had been well taken up, and the increase in the demand for electrical energy for heating and cooking had been very noticeable.

Vickers, Sons & Maxim.—The report for 1910, which recommends a dividend making a total of 10 per cent. for the year, states that all departments of the company were more fully occupied during the year than in the previous twelve months. It is further anticipated that the current year will show still further improvement, as the orders in hand, both for home and abroad, are unusually heavy. After meeting the above dividend, a balance of £103,970 is carried forward. It is proposed to change the name of the company to "Vickers, Ltd."

British Insulated & Helsby Cables, Ltd.—At the annual meeting on Monday, Mr. James Taylor, the Vice-Chairman, who presided, stated that the transfer of the telephone system to the Government had resulted in the placing of a large number of orders for telephone material, a fair proportion of which had been given to the British Insulated Company.

Royal Institution.—The programme of Friday evening meetings after Easter includes a discourse, on June 2nd, on Radio-telegraphy, by Mr. G. Marconi. Among the Thursday afternoon lectures will be two by Mr. T. Thorne Baker, on "Changes Effected by Light" and "Practical Progress in Wireless Telegraphy" respectively.

Parliamentary Intelligence.—The London County Council Tramways Bill was before the Standing Orders Committee last week in respect of absence of consents of road authorities for certain tramways. It was decided to allow the Marble Arch to Cricklewood tramways to proceed, but a number of proposed tramways were struck out.

The London, Tilbury & Southend Railway Bill was before a Committee of the House of Lords last week. One of the chief proposals of the Bill is to acquire land for the erection of a generating station at Tilbury and Thames Haven. The company have hitherto obtained their supply of electrical energy for working such portions of their lines over which electric trains run from the Lot's Road power-house, but it is intended to extend the electrification over the whole of the lines. Hence the need for their own power station. There was very little opposition to the scheme, and the preamble of the Bill was found proved. Mr. Robert Hammond gave evidence on behalf of the railway company.

A clause in the Great Northern Railway Bill, which was passed by a Committee of the House of Commons on Thursday, gives authority to take a supply of electrical energy from the Great Northern and City Railway Co. At present the company get the supply of electrical energy which is required for lighting, &c., from their own power station at Holloway, but the cost of generation is very heavy, and a cheaper supply can be obtained from the Great Northern and City Railway Co.

Gas v. Electricity.—At the annual meeting of the Sheffield United Gas Light Co. last week, some strong statements were made by the Chairman, Mr. Wilson Mappin, with regard to the electricity supply in general and the Sheffield electric supply undertaking in particular. He said that the electrical industry have what is called a Publicity Department, whose occupation seems to be to turn out literature vilifying gas in all its uses. Some of these pamphlets he had seen, and they were absurdly extravagant in their inaccuracies. He referred to experiments made at the Lewisham Infirmary, which demonstrated that the use of gas, both as an illuminant and for heating purposes, assisted the ventilation, a statement which puts the results in question somewhat higher than did Mr. F. W. Goodenough, of the Gas Light & Coke Co., at the annual meeting of the Illuminating Engineering Society last week. We would also refer Mr. Wilson Mappin to Dr. Harman's views on the use of gas expressed at the same meeting, viz., that when it was contended that gas assisted ventilation, it was a sign that gas was on its last legs. Dealing with the Sheffield Electricity Department, Mr. Wilson Mappin objected to the offer which is being made to supply current for lighting at a discount of 50 per cent. on condition that all gas-burners were removed from the consumers' premises. Nevertheless, he contended that even at 2d. per unit with metal filament lamps, the cost of lighting by electricity would still be more than double that of gas. Mr. Wilson Mappin also repeated the usual statement that the City of London and the City of Westminster have displaced electricity by gas, whereas our readers hardly need reminding that only a very few lamps have been displaced in Westminster, and that in the City of London experiments are being carried out with a view to finally determining the question.

SUMMARY

A Paper by Messrs. H. A. Ratcliff and A. E. Moore, read before the Institution of Electrical Engineers on Thursday last, discussed the merits and faults of the various types of D.C. and A.C. meters, and contained much useful information about testing. The authors are strongly in favour of watt-hour meters as opposed to ampere-hour meters. Some objections were raised against the mercury motor meter, while commutator type and electrolytic ampere-hour meters were very severely criticised. The Aron meter was highly spoken of. Tests on the effect of wave form on A.C. meters, and experiments proving interaction between the elements of polyphase motors, were described. The discussions in London and Manchester brought out many interesting points. (Page 163.)

A table of statistics of the comparative cost of street lighting by gas and electricity in different towns and boroughs has been prepared by the Wimbledon Electricity Department. (Page 165.)

Among the Specifications published by the Patent Office on Thursday last was one by the Foster Arc Lamp & Engineering Co. for a water heater comprising two concentric cylinders with a helical water passage between them, and connected to a transformer within the inner cylinder. A rail bond of fine wires to give flexibility, and armoured with heavy wire, is covered by the British Thomson-Houston Co. A patent by G. Ellison for a time-lag device for circuit breakers has been granted in spite of opposition. The patent for the Johnson-Lundell field construction for motors, in which a single field coil is used, and a patent by F. Steinert for a magnetic separator, expire during the current week after the full life of fourteen years. (Page 166.)

A system of non-interchangeable cartridge fuses is described, some curves of life tests of a particular make of metal filament lamp are given, and an instrument for calculating motor horse powers and currents is explained on page 167.

A letter from Simplex Conduits, Ltd., continues the discussion on meters and defends the commutator motor type. (Page 167.)

We describe highly satisfactory tests which we have carried out on some soldered aluminium joints. The new flux and solder used are applied in the usual manner. (Page 168.)

The Luton Corporation Bill, which was passed by a House of Commons Committee last week, contains municipal wiring powers, but the work is to be carried out through contractors. (Page 168.)

The Glasgow Assessment Committee have refused to alter the assessment of the tramways, and the Tramways Committee are appealing.—Stepney Borough Council have again refused to allow the trolley system in their district.—An increase of ½d. per unit for private lighting is to be made at Beckenham to counteract the reduced revenue due to metal filament lamps.—The Fulham Council have refused to adopt a suggestion of the L.C.C. to repay some existing loans in 20 years instead of 42 years.—The Victorian Government propose to purchase the Melbourne tramways.—The Hammersmith Council are to undertake the wiring and fitting of lamps for outside shop lighting, but to carry on the work through contractors. (Page 169.)

Hosted by Google

SWITCHBOARD extensions are required at Handsworth; cable and troughing at Rugby; reversible booster and switchboard at York; motor-generator and balancer, and arc lamp carbons at St. Pancras; boilers, generator, and condenser at Bermondsey; flame arc lamps at Blackpool; and a 1,500-kw. turbo-alternator, condensing plant, and switchgear at St. Helens. Loans have been sanctioned as follows:—Beckenham, £6,000; Battersea, £1,400; Hackney, £20,599; Bury, £72,000; Kettering Corporation propose to take up a loan of £13,100. A generating plant is required at Cavan (Ireland), and three years' supply of electrical fittings is required at H.M. Office of Works. (Page 169.)

AFTER meeting all charges, the British Aluminium Co. is enabled to carry to reserve the sum of £4,943 as a result of the trading for 1910. A satisfactory report for 1910 is made by the South Wales Electrical Power Distribution Co. There was a loss of £9,300 for 1910 by the Durham Collieries Electric Power Co. New capital is being issued by the Lancashire Electric Power Co. (Page 171.)

The Telephone Service.—We have received from Mr. H. Laws Webb a long letter, in which he repeats his plea made in a Paper read in February before the London Chamber of Commerce for the establishment of a Board on which the Government, Municipalities, and Chambers of Commerce would be represented, to conduct the telephone system instead of the transfer of the whole to the Post Office.

Birmingham Local Section of the Institution of Electrical Engineers.—The Committee are putting forward the following list of nominations for the officers for the session 1911–12: *Past Chairmen*—R. A. Chattock, Gisbert Kapp, R. K. Morcom. *Chairman*—M. Railing. *Vice-Chairman*—A. M. Taylor. *Present Ordinary Members of Committee (remaining in office)*—J. H. Barker, W. C. Goodchild, M. Kloss, W. J. Larke, F. M. Lea, F. J. Moffett, D. K. Morris, C. E. C. Shawfield, W. E. Sumpner, R. Threlfall. *Ordinary Members of Committee*—M. Solomon, J. J. Steinitz. *Hon. Secretary*—H. B. Matthews. Any further nominations must reach the Hon. Sec. by April 19th. If none are sent in, the above gentlemen will be declared elected at the annual meeting on May 3rd.

ARRANGEMENTS FOR THE WEEK

FRIDAY, MARCH 31ST.

Institution of Civil Engineers.

8 p.m. Lecture II.: "The Uses of Chemistry in Engineering," by J. Swinburne, F.R.S.

WEDNESDAY, APRIL 5TH.

Institution of Electrical Engineers: Yorkshire Section.

7 p.m. At Leeds University. "Public Electric Supply in Country Districts," by W. B. Woodhouse.

THURSDAY, APRIL 6TH.

National Electrical Manufacturers' Association.

2.30 p.m. Council Meeting at Balfour House, Finsbury Pavement, E.C.

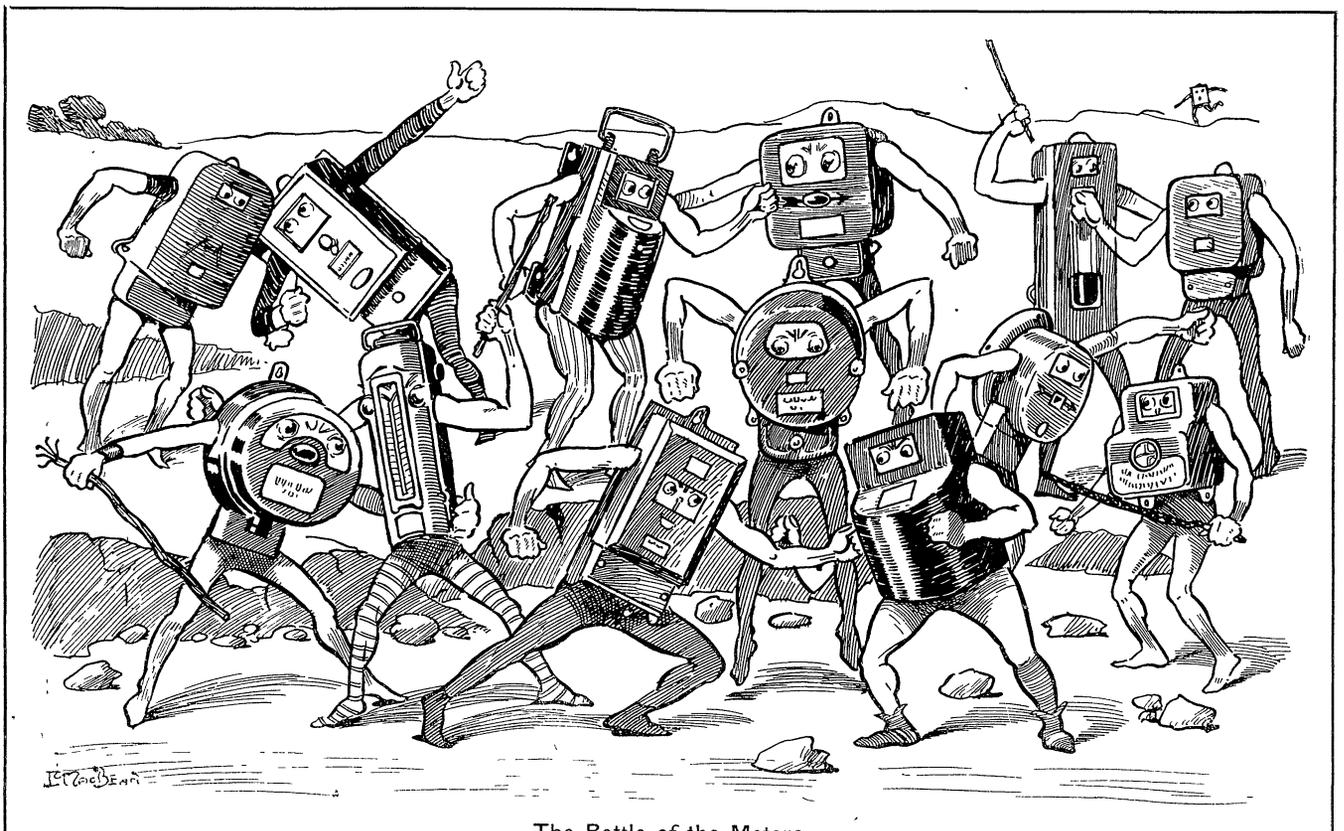
Institution of Electrical Engineers.

8 p.m. "Wireless Telegraphy Working in Relation to Interference and Perturbations," by J. E. Taylor.

Institution of Electrical Engineers: Dublin Section.

8 p.m. At Royal College of Science.

FRIDAY, APRIL 7TH.



Royal Institution.

9 p.m. Evening Discourse:—"A New Method of Chemical Analysis," by Prof. Sir J. J. Thomson, F.R.S.

"Mazda" Trade Mark.—Mr. Justice Swinfen Eady on Friday granted an interim injunction against Messrs. T. L. Scott & Co. preventing the use of the trade mark "Marsa" in connection with the sale of electric lamps. The interim injunction was granted on the application of the British Thomson-Houston Co., Ltd.

Constantinople Telephone System.—After very protracted negotiations, a concession has been granted for the establishment of a telephone service in Constantinople. As we have previously pointed out, the negotiations have been carried on by Mr. H. Laws Webb, representing a combination of the National Telephone Co., Ltd., Western Electric Co., of America, British Insulated & Helsby Cables, Ltd., and the French British Thomson-Houston Co. The first exchange to be constructed will provide for 10,000 subscribers. The total area to be served is 150 square miles, and as Constantinople is divided by the Bosphorous, a number of submarine telephone cables will have to be laid.

Meters Approved.—The Board of Trade have approved the following meters:—Westinghouse, types N. and A. polyphase watt-hour meters; Chamberlain & Hookham, two-rate C.C. meter; Ferranti polyphase watt-hour alternating-current meter; Electrical Co.'s three-phase induction watt-hour meter, type D. 3; and the Aron polyphase motor-meter, type H.

The Battle of the Meters.

ELECTRICITY METERS

A PAPER by Messrs. H. A. Ratcliff (Manchester Electricity Department) and A. E. Moore (Manchester Municipal School of Technology), read before the Institution of Electrical Engineers in London on March 23rd, and before the Manchester Section on March 21st, discussed the merits and demerits of the various patterns of A.C. and D.C. meters, and included some useful notes on testing. The authors consider that as a rule meters should be overhauled and recalibrated at the end of five years. Where low rates of charging are in force an error of 2 or 3 per cent. may make all the difference between profit and loss, and in such cases the authors suggest that duplicate meters should be installed. Considering first D.C. meters, the authors hold that only watt-hour meters should be legally recognised, as apart from measuring the energy correctly independently of voltage variations, they may be compounded so as to start with exceedingly small currents. They consider that the shunt losses in watt-hour meters are far less important than the loss of revenue with ampere-hour meters, due to the fact that the mains pressure is often above the declared pressure.

Of the three types of ampere-hour meters, the mercury motor meter is that most largely used in this country. It is difficult to get a sufficiently high driving torque in small meters of this type. The most frequent fault is amalgamation, which seems to be only a matter of time even with the best protected armatures. Oxidation of the mercury also occurs in time. A new design employs an extremely small air-gap, and an amalgamated armature devoid of compensation for friction, but this would only give good results if the copper and mercury could be kept chemically pure. It is now usual to shunt all mercury meters above 50 amperes, and some makers shunt above 10 amperes. This also reduces the temperature error, but, unless the inductances of the two circuits are balanced, errors will be introduced on fluctuating loads.

The commutator type D.C. ampere-hour meter will, the authors consider, soon be discarded on account principally of its susceptibility to changes in brush position and contact resistance. Typical curves plotted from the mean results of a large number of meters show that whereas the error of the mercury meters tested was not more than 1·5 per cent. between one-tenth and full load, that of the commutator meters averaged 7 per cent. at one-tenth load, though they were of better accuracy at medium loads, the meters being calibrated for accuracy at full load in each case.

Turning to electrolytic meters, the authors state that "their disadvantages . . . so completely outweigh their advantages that they can hardly be regarded as cheap, even at the present low prices." They have not the extreme accuracy claimed, and the lack of a continuously registering device is a serious matter. Correct reading of the scale is difficult, and the construction is generally fragile. A most frequent source of trouble is leakage of the electrolyte between the glass and the platinum leading-in wires.

D.C. watt-hour meters are nearly all on the true dynamometer principle, a notable exception being the Aron meter. The simple revolving armature type, if sold at a reasonable price, should be a serious rival to the mercury ampere-hour meter. The authors consider the small-diameter commutators frequently used to be very unsuitable, and prefer robust commutators with a larger number of segments. Footstep bearings are a frequent source of trouble, owing to the comparatively heavy weight of the rotating portion. A spherical-ended shaft is to be preferred to a pointed one, and the use of a ball-bearing is suggested. The removable spindle-tips used by one well-known firm are a distinct advance.

The Aron meter, the authors state, is probably the most complicated, but at the same time the most reliable watt-hour meter made. It is astatic, and therefore not affected by stray fields, and is not affected by momentary overloads or short circuits. A definite indication is given when the meter is out of order, and it is very unusual for a gradual error to develop. When shunted, however, it cannot be used on A.C. circuits, and in all patterns testing is difficult. A frequent source of trouble is pitting of the pendulum arbor pivots, probably due to chemical action caused by the vulcanised fibre blocks used for insulating the terminals, a material which is in any case unsuitable for use in meters or instruments. There are about twenty-four clamped connections in the shunted type, and as the drop in the shunt is only 0·2 volt at full load, troubles due to bad contacts are only a matter of time unless the contacts are soldered. After considerable experience, however, the authors consider that a meter free from permanent magnets, such as the Aron meter, is the only type capable of withstanding the severe conditions which exist in large D.C. stations, as overloads and external fields are sufficient to destroy the calibration of all meters with permanent magnets. One of the authors has seen a dynamometer watt-hour meter stop at about one-third load, and actually reverse at one-quarter load due to the effect of a stray field. The effect of the series coils of a meter in the case of a short circuit is also often very considerable. The permanent magnets should be carefully shielded and the torque-producing coils astatically wound.

The authors consider that shunts are undesirable on any type of meter, and should be avoided for all meters not exceeding 1,000 amperes capacity. With regard to tramway meters, they do not think that there is a meter on the market capable of withstanding the severe conditions for any length of time.

The induction type A.C. meter, continue the authors, probably represents 75 per cent. of the total sales of A.C. meters, but for station work and heavy-service conditions, where accuracy and reliability are essential, the dynamometer types are to be recommended. Probably the best method to increase the driving torque of induction meters is to increase the driving fluxes and to use a stronger braking system instead of increasing the size of the rotating part. A lower speed gives better accuracy. The quadrature adjustment can be made by testing the meter with a lagging and a leading power factor, and also at unity, the quadrature being regarded as correct when the error is the same under all three conditions.

Dynamometer meters are unsuitable for working off current transformers on circuits with low power factors, as the error due to the inductance of the volt coils is intensified by the effect of the lead in the transformers. This error can be partially corrected by eddy currents induced in suitable closed circuits or by shunting the series coils; but the meter will only then be suitable for one frequency, and will be affected by changes in temperature and wave-form.

The accuracy of polyphase meters, which are often only single-phase meters, depends on many assumptions the correctness of which is doubtful. The only reliable ones are those consisting of two or more single-phase elements which admit of being tested separately on a single-phase circuit, the measurement of energy being obtained on the principle of the "two wattmeter" method of measuring power.

Turning to testing, the authors emphasise the importance of connecting up the shunt coils of a meter at least half an hour before observations are commenced in order that the normal running temperature shall be reached. The shunt and series coils are supplied from different sources, and, in both cases, if transformers are used, it is important not to adjust by means of resistance in the primary, as this alters the wave-form in the secondary. Of the different methods of phase adjustment, the use of two machines, one provided with a movable stator, is considered the best. A combined phase adjuster and voltage regulator has been used successfully by the Manchester Electricity Department for several years. This consists of an ordinary D.C. drum armature surrounded with a ring of tightly fitting annealed iron stampings. The three-phase supply is connected to the winding at six equidistant points, and a rotary field is produced. The brushes bear each on one segment only of the commutator, and cannot bridge across the insulation.

The authors describe several series of tests. One set shows that it is not satisfactory to obtain different phase relations by connecting the series coils of the meters to one part, and the shunt coils to another part of a three-phase system, as the theoretical phase relations are disturbed by the unbalanced load. Other tests show that the readings of all makes of induction meters are affected by variations in wave-form, and that with certain very abnormal waves errors as high as 27 per cent. can be produced. Meters of the dynamometer type, however, are hardly affected at all. Investigations were also made with polyphase meters, and the tests show how the power factor of the system affects the ratio of the watts on the two meters, and also how the equivalent power factor of each meter is affected by the power factor of the load. Finally, some tests are given showing that there is considerable interaction between the two elements of polyphase meters, with the result that the speed of the meter is appreciably affected by the relative phases of the two fluxes.

DISCUSSION IN LONDON.

Mr. S. H. HOLDEN (Messrs. Chamberlain & Hookham) suggested that the Engineering Standards specification should state what errors due to variations in wave form were to be allowed, and also give instructions as to how meters were to be tested. He had known many mercury meters which had been in use for seven or eight years, and still registered accurately. He knew of several makers of tramcar meters who were prepared to guarantee to keep them in working order for 20 years at 3s. 3d. per meter per annum, and in this connection he read a letter from Mr. Baker, the General Manager of the Birmingham Corporation Tramways, which stated that since December, 1909, all his cars had been fitted with meters, and that during the past twelve months a saving in current amounting to £5,000 had been effected, in spite of the cars having run 50,000 more car miles In addition, there had been considerable savings in the wear of brake shoes, wheel tyres, &c., consequent upon the more careful management of the cars by the drivers.

Mr. S. W. MELSOM (National Physical Laboratory) said that meters were usually calibrated at about 15° C., and used in a power station at about 25° C., and he suggested that makers should label their meters with the temperature at which they were standardised and the temperature coefficient. Another source of error was the heating inside. It was found at the National Physical Laboratories that some meters heated up very considerably; in one case there was a difference of nearly 5 per cent. at full load between the reading when the meter was cold and that after it had had time to heat up. The comparison of watts lost in mercury meters and watt-hour meters was very unfair. The Engineering Standards specification prescribed 4 watts per 100 volts, and records showed that the average pressure coil losses in 200-volt watt-hour meters were 6 watts, and not 4 watts as taken by the authors. Further, the losses in the main current coils of watt-hour meters were about three times as large as in the current circuit of any ampere-hour meters.

Mr. E. GARTON, referring to the new mercury meter with amalgamated armature, said that he had been obtaining both copper and mercury chemically pure for the last four or five years. He agreed that the induction meter was more efficient than the dynamometer type. He did not think that central station engineers would agree that an increase in the price of meters was justifiable. With regard to the alleged errors in shunted mercury meters due to variations in resistance of the bath, he pointed out that in a certain meter which he had tested the drop across the bath was only two millivolts, whereas that across the leads in series with it were 30 millivolts. Consequently, if the full resistance of the bath was even doubled, which was extremely unlikely, the error would only be from 6 to 7 per cent.

Mr. L. W. WILD (Westminster Testing Laboratories), referring to his own experiments on the effect of wave form, said that with peak waves he had obtained errors in one direction, and that with smooth flat-top waves the errors were in the opposite direction. According to the authors' results, however, the errors were in the same direction in both cases, but the authors' flat-top curves were not smooth, and had features peculiar to the peak wave. His practice in testing polyphase meters was to connect the current coils in series and the shunt coils in parallel, and to take two tests, reversing the connections. This often gave a difference of as much as 2 or 3 per cent., and he took the mean. Interaction troubles were bound to occur unless one could get the phases exactly as under working conditions, and he thought the above method was as good as any. He did not think it difficult to measure the ratio and phase differences of series transformers, but he agreed that it was necessary to test meters with their series transformers, as even in the case of single-phase meters there were interactions between the volt and ampere coils when transformers were used.

Mr. K. EDGCUMBE (Messrs. Everett Edgcumbe & Co.) said that a most difficult class of meter user to deal with was the isolated plant which in the ordinary course had a very small load for 360 days of the year, while during the remaining 5 or 6 days some very big functions were held and the load went up enormously. In this case he thought the right thing to do was to adjust the meter accurate for low loads and let the accuracy of the upper part of the curve look after itself. The authors had adopted a rather roundabout way of adjusting for quadrature. It was simpler to adjust for standing still at 90° out of phase, although the authors apparently raised the objection to this that the watt-meter used could not be relied upon. It was more satisfactory to use a power-factor indicator for the purpose.

Mr. C. A. BAKER (London County Council) suggested that meters of large consumers should be checked every three or six months. The references in the paper to the ampere-hour meter showed the necessity for having pressure testing stations on mains. At present there were 40 such stations in London, and others were being equipped. He agreed with the authors' criticisms of the electrolytic meter. It was surprising that these meters had ever received the Board of Trade approval. The 1 per cent. error suggested by the authors was highly desirable. On top loads most meters came well within 1 per cent. He was sorry to see the Board of Trade dropping the light load test on meters altogether, below one-tenth load, for anything except small ampere-hour meters. The difficulty with regard to country house plants also existed in connection with certain town houses, which during nine or ten months of the year were only burning a few lights, but were paying large bills because the meters were working on the low part of the curve, and were not registering very accurately.

Mr. A. P. TROTTER did not agree with the authors in regard to the relative losses of ampere-hour and watt-hour meters. The watts lost in the coils of the latter were very serious, and larger than those of the ampere-hour meter, and for this reason it was impossible to make a small watt-hour meter, *e.g.*, for a current, below three amperes. Now was the time to encourage the small meter, and if small meters were not going to be made, supply undertakers could do without meters altogether. Dealing with the Board of Trade approval of meters, he said that a commutator ampere-hour meter with an error curve such as that given in the Paper would never pass the Board of Trade test, nor would a meter which was likely to get into that state after two or three years. He had been blamed apparently for passing an electrolytic meter, but he did not want to discourage the new designs of meters that were being manufactured. There were at present 38 different patterns on the market and 20 in hand, and the various electrolytic meters that he had seen were not so bad as was suggested. The authors had high ideals as to the permissible percentage error, and he could not help feeling that a 1 per cent. error could not be had at present prices. A rather larger error might be allowed for polyphase meters than for singlephase meters, because of the great difficulty of balancing. With regard to the wave-form tests, the consumer with a big load, seeing differences of 20 per cent., might ask what was the good of having a meter at all, and the authors should have pointed out that they were somewhat fancy curves and not found in practice. Ever since the Board of Trade Laboratory had started, the inspectors were instructed to insist upon a maximum error of 2½ per cent., plus or minus, above one-tenth load for ordinary meters of ordinary sizes. Some years ago it was found that there was a very obvious demand for small meters of less than 3 amperes, and in the case of these small meters it was suggested, in order to encourage them, that the error should not be more than 3½ per cent., plus or minus. This had been going on for the past ten years. With regard to the larger meters, it was on the suggestion of the London County Council that the Board of Trade made provision for meters above 50 amperes. These were tested for a maximum error at one-twentieth full load of 2½ per cent. plus.

Mr. S. EVERSHED (Messrs. Evershed & Vignoles), referring to the demagnetisation of brake magnets, said that the short-circuit current on an ordinary 100-volt circuit, when the fuse was blown, was 30 times the full-load current. Professor Schwarz had proved that the current had ample time to reach its steady value, and this was easy to calculate. It was only necessary (by putting full-load current through the meter) to determine the ratio of the drop across the meter to the supply voltage, and this gave the figure by which they must multiply the full-load current to find the short-circuit current. If the drop was 3 volts and the supply 100 volts, then the short-circuit current would be 30 times. In most types of meters under these conditions the magnets would be either partially or absolutely demagnetised, and the only way of getting over it was to make the meter larger. Finally, he gave a formula representing the accuracy of the commutator type ampere-hour meter, and asserted that the makers had not taken advantage of any of the possible methods of improving the accuracy. The best meter of this pattern he had tested had an error of 20 per cent. at one-tenth full load.

Mr. RATCLIFFE, in reply, expressed the opinion that 12 months was the outside limit for reasonable accuracy with tramcar meters. With regard to temperature error, the authors specified a maximum limit of variation with temperature rise, although they would like to get a greater degree of accuracy. In the Aron meter the temperature error was practically nil. With regard to the calibration of meters for isolated plants or town houses, he did not know what the legal position would be if accuracy on the higher loads were ignored. He had not yet come across a really satisfactory single-phase power-factor indicator. He thought a very good small watt-hour meter could be made with a drop of 1½ volts. The trouble with the small commutators was not only mechanical, as the insulation often broke down.

Mr. MOORE also replied briefly.

A letter dealing with this discussion will be found on page 167.

DISCUSSION AT MANCHESTER.

Mr. G. NORTH (British Westinghouse Co.) said that the loss of revenue due to defective meters was usually far more important than the pressure coil loss. The saving with watt-hour meters due to increased registration at low loads as compared with ampere-hour meters would more than compensate for the pressure coil loss. Speaking as a meter manufacturer, he would point out that it was quite possible to reach high

Hosted by Google

accuracy, but that manufacturers could necessarily only make their meters as good as was consistent with the price obtainable for them. How often was the Aron meter used as compared with other less perfect types of meters? Commutator meters could be obtained to give fairly consistent results with direct current, but were absolutely no good on A.-C. circuits, as the vibration of the moving element wore out the jewels and pivot bearings in one-quarter the length of time they lasted on D.C. circuits. The induction meter was, he thought, the nearest approach to the ideal. A high torque was not so necessary, as there was no brush friction. Induction meters were bound to be affected by wave form, but the authors' tests showed that a sufficient degree of accuracy was obtainable under practical conditions. He never recommended the balanced type of polyphase meter, but one generally had to quote customers for both the balanced and unbalanced patterns.

Mr. H. E. TRENT (General Electric Co.) said that errors were largely due to the meters being placed in abnormal positions as regards temperature and stray fields. One could not expect a cheap, thin iron case to shield a meter against the stray fields if it were placed close to the 'bus-bars.

Mr. A. E. JEPSON (General Electric Co.) thoroughly agreed with most of the remarks in the Paper. Watt-hour meters could be bought for a very few shillings more than ampere-hour meters, and the extra cost was often soon paid for where the voltage was above normal. A black powder, apparently pure mercury, was found in the mercury chambers of some meters, and this might alter the resistance of the bath and cause errors in a shunted meter. He thought that a good commutator type ampere-hour meter could be obtained if a good price were paid for it. Repairs were very simple with this pattern. A damped type meter should not require a higher working pressure across the armature. It was essential that jewel bearings should be mounted on springs to prevent breaking of the jewel. Referring to the criticisms of the Aron meter, he did not think the testing any more difficult or tedious than that of other meters. Partial shunting of the pendulum coils due to dirt between the commutator segments was rare and easily remedied. Pitting of the pendulum arbor pivots was now prevented by the use of an acid-free insulating material, "Stabilit." All the connections in the shunted circuit were now soldered.

Mr. F. WALKER mentioned a meter which had been working for eight years, and was now, if anything, more accurate than when it was first put in.

Mr. W. GRANT (Manchester Municipal School of Technology) did not think that a supply authority could legitimately charge for excess units caused by the supply pressure being above the normal. The lamps were overrun and the consumer was paying for something he did not want. Commutator type ampere-hour meters were very flimsy, and were often unprotected from external fields. With regard to polyphase meters, one firm recommended the use of two separate meters, on account of the interaction troubles with a combined meter.

Mr. R. G. CUNLIFFE (Manchester Corporation Tramways) said that about 20 tramcar meters were being used in Manchester with perfect success, the results not varying more than 5 per cent. from month to month.

Mr. BOLTON SHAW thought that the many advantages consequent upon the use of two single-phase meters on polyphase circuits justified the extra cost as compared with a combined meter. Any change in the ratio of the two instruments was readily noticeable on the log sheet before the error affected the record to any extent. Two single-phase meters also provided a means of estimating the average power-factor over any period.

Mr. L. C. BENTON (British Westinghouse Co.) understood that the authors preferred a polyphase meter to two single-phase meters. Manufacturers could not, he said, be expected to attain 1 per cent. accuracy until the tests by various standardising laboratories agreed within this degree. Tests on large meters on inductive loads were by no means in close agreement.

Mr. W. CRAMP asked whether the authors had made tests of accuracy with meters running in the reversed direction. He thought that the extreme accuracy desired might not justify the cost of obtaining it; the accuracy now obtained was far in advance of that of gas meters. Permanent magnets could be made of such a shape that the yoke shielded the poles. The accuracy of the Aron meter was due, he thought, to the fact that the timing mechanism was driven independently of the registering mechanism.

In reply, the authors held that the higher voltage drop of commutator ampere-hour meters of the damped type had been proved by tests. Experience showed that the curves of Aron meters were not always straight lines, and that tests on several loads were necessary. The testing temperature fixed by the British Engineering Standards Committee was 60° F., and was probably a fairly average one. It was not unusual for the mercury to be shot out of mercury motor meters as a result of a severe short-circuit. They had had no experience with reversible meters. D.C. meters were not, as a rule, accurate when reversed, and A.C. meters would also not be accurate if compensated for friction in one direction only. Excellent results had been attained with Aron reversible battery meters.

COST OF STREET LIGHTING: GAS COSTS NEARLY THREE TIMES ELECTRICITY

MR. H. TOMLINSON-LEE, Chief Electrical Engineer to the Wimbledon Borough Council, has sent us a table compiled by Mr. Dudley Stuart, Chairman of the Lighting Committee, and himself, which compares the cost of gas and electric street lighting in twenty-eight towns and boroughs. The table is calculated from particulars obtained from the public authorities themselves last December, and the figures include all renewals, repairs, and attendance:—

TOWN OR BOROUGH.	Cost per c.p. per ann. Electr.	Gas.	TOWN OR BOROUGH.	Cost per c.p. per ann. Electr.	Gas.
	Pence.	Pence.		Pence.	Pence.
Bournemouth ...	3·82	7 51	Kingston ...	8·21	19·27
Blackpool ...	7·28	21·60	Lambeth ...	——	10·47

* Candle power estimated.

It is seen that the most extreme case is that of Islington, where electric light for the same candle power costs less than one-fifth that of gas; in this case the majority of the electric lamps are arc. At Fulham, however, where there are 914 incandescent electric lamps and 226 arcs, the ratio of the cost of gas and electricity is about the same. The best figures for gas are at Chelsea, Finsbury, and Southwark, and in the first two of these inverted burners are employed. Even these are far greater than the lowest figures for electric light, and well above the average.

The statistics sent us also give the total cost of lighting per annum per mile of street, including both gas and electric lighting, and this varies from £60 to £377, with an average of £152. The approximate lighting rate per £ per annum varies from 1·4 to 5·67 pence, with an average of 2·78 pence. The total candle power used per mile also shows wide variations—from 968 to 12,165, with an average of 4,892.

Of course the whole value of these figures depends on the way in which the candle powers have been estimated, as there are difficulties in the comparison of lamps of different distribution curves on a candle-power basis alone. In all probability, however, this error has cancelled out fairly well in the final averages, and, in any case, the superiority of electric lighting is very clearly demonstrated.

Faraday House.—We are informed that the annual dinner of the Faraday House Old Students' Association will be held at the Holborn Restaurant, London, W.C., on Wednesday, April 26th, at 7 for 7.30 p.m. The President for the year—Mr. H. H. Perry, of the North Metropolitan Electric Power Supply Co.—will be in the chair. All Faradians who wish to be present are asked to communicate with the Honorary Secretary, Faraday House.

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the Institution of Electrical Engineers on Thursday:—*Members*: S. S. Moore Ede, G. M. Harriss, P. L. Riviere. *Associate Members*: H. R. Baldwin, J. Burbridge, R. W. Clark, A. C. Coward, G. F. Findley, H. G. Jeken, E. W. Kay, W. C. Kirwan, F. E. Mitton, W. O. Pepper, W. G. Pickvance, H. K. Reed, P. M. Sanger, L. M. Silver, J. H. Thomas, E. O. Turner, W. F. White, J. L. Wilson. *Students:* E. P. Ashworth, A. J. Bates, S. Burns, W. G. Corben, L. G. Dimmer, W. D. Douglas, G. H. Elsden, W. S. Flight, E. A. Gordon, W. S. Harvey, W. E. Hatfield, H. J. Henwood, G. A. Hollings, G. Hughes, E. W. King, R. Levy, L. Lewis, C. W. Marshall, J. Meikle, M. A. Moharram, L. Norris, D. V. Oppenheim, A. C. Patel, R. L. Printz, E. L. Protheroe, H. W. Puttick, A. R. Teixeira, J. A. Tilburg, F. J. Tompson, R. Wenning.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published March 23rd, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

5,388/10. **Metal Filaments.** WESTINGHOUSE METAL FILAMENT LAMP CO. and A. LEDERER. Metal filaments purchased from manufacturers are further decarbonised by heating in an atmosphere of pure dry hydrogen only, as described in patent No. 6,936 of 1909. This permits of the amount of carbon present being reduced to 0·04 per cent.

6,065/10. **Water Heater.** FOSTER ARC LAMP & ENGINEERING CO. and M. V. ELY. A water heater for A.C. circuits consists of two concentric metal or carbon cylinders with an annular space between them for the water to flow through. This space is divided by means of insulating partitions into a helical passage. A transformer is situated within the inner cylinder, and its secondary is connected to the two cylinders, so that a heavy current flows through the water. As the voltage is very low, there is no danger of shock. Three figures.

8,363/10. **Electric Locomotives.** A. F. BATCHELDER (Schenectady, U.S.A.). In heavy locomotives, the motor is mounted directly over the driving wheel, and is connected by a coupling rod to an intermediate crank and axle in the same plane as the driving-wheel axle. In one design illustrated there are three driving wheels coupled together, and two driving motors mounted directly over the two outer driving wheels are coupled to intermediate axles at the ends of the locomotive, and in a line with the driving axles. One- or two-axle leading trucks are provided at each end of the locomotive. Five figures.

11,275/10. **Lamp Holder and Plug.** LONGSTRETH'S, LTD., and A. BAKER. A lamp holder for vehicles, &c., has an ordinary bayonet coupling above for engaging with the lamp cap, but has a socket underneath with a reversed coupling for the plug. The bayonet pins projecting inwardly from the socket, and bayonet grooves are provided on the plug connected to the flexible leads. Seven figures.

12,265/10. **Electric Driving of Rolling Mills.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). When an induction motor is used for the main drive, and a D.C. motor for driving the finishing strand, trouble may arise with varying load due to relative speed variations between the two motors. This patent describes apparatus responsive to speed variations of the induction motor for controlling the speed of the D.C. motor so as to maintain a proportionality of speed between the two, and thus prevent the steel from buckling as it passes to the finishing strand. One figure.

25,964/10. **Speed Control of Polyphase Motors.** SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens Schuckertwerke Ges.*). The speed of polyphase commutator motors is usually varied by altering the voltage applied to the rotor winding through the commutator. According to this invention, the control is effected either by maintaining the total of the stator and rotor voltages constant and varying the exciting field, or by altering both voltages and field. The former is suitable when the torque decreases as the speed rises, the latter when the torque decreases with the speed. Various arrangements of the transformer connection between the stator and rotor circuits are described. Five figures.

30,138/10. **Rail Bonds.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). In order that a rail bond may be both flexible enough to withstand the constant vibration without crystallising and breaking, and strong enough to withstand impact and abrasion, it is constructed of small gauge wires with an armouring of heavy gauge wires. In another form described, the body consists of concentric layers of strands of increasing thickness towards the exterior. Three figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: JABURG, 13,305/10.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: FRANCE [Wire, cable and tube joints] 6,138/10; SHARP [Insulating compound] 9,933/10; BEAVER, PREECE and CLAREMONT [Cable] 11,792/10; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Resistance wire alloys] 14,743/10; CHAMPION [Junction boxes] 15,731/10.

Dynamos, Motors, and Transformers: SIEMENS-SCHUCKERTWERKE GES. [Speed regulation of machines] 16,997/10; JOHNSON-LUNDELL ELECTRIC TRACTION CO. (*Lundell*) [Regenerative motors and their control] 21,339/10.

Electric Ignition: HALL [Sparking-plugs] 6,104/10; SIMS MAGNETO CO. [High-tension magneto apparatus] 16,844/10.

Electrometallurgy and Electrochemistry: WASSMER [Electric furnaces] 28,813/09; URBAIN, FEIGE & SCAL [Electric arc apparatus for sterilising liquids] 5,393/10; HEROLD [Primary cells] 13,739/10; A.-G. FÜR OZONVERWERTUNG (SYSTEM ELWORTHY-KOLLE) [Ozone apparatus] 3,119/11.

Heating and Cooking: BASTIAN [Domestic apparatus] 6,207/10.

Incandescent Lamps: SCOULAR and EVERETT, 5,289/10; STODD, 11,931/10; HARRISON, 15,424/10.

Switchgear, Fuses, and Fittings: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Lightning arresters] 211/10; ADAMS MANUFACTURING CO. (*Cutler Hammer Mfg. Co., U.S.A.*) [Motor controllers] 5,278/10; CREESE and DEDERICH [Switches] 5,465/10; HALL [Cable terminals] 6,431/10; ADAMS MANUFACTURING CO. (*Cutler Hammer Mfg. Co., U.S.A.*) [Speed controllers for motors] 13,406/10; ELECTRIC & ORDNANCE ACCESSORIES CO. and GARNER [Motor starters] 17,344/10.

Telephony and Telegraphy: WILLIS and JOHNSON [Signalling apparatus] 101/10; CONNER and PEEL-CONNER TELEPHONE WORKS, LTD. [Telephone systems] 14,916/10.

Traction: GRESHAM and KIERNAN [Vacuum brakes] 6,284/10; A.-G. BROWN BOVERIE ET CIE. [Drive of electric vehicles] 6,403/10.

Miscellaneous: BARCLAY [Prevention of overwinding] 20,182/09; HAILWOOD [Testing miners' lamps] 7,388/10; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Watchman's clock recorder system] 13,216/10; KAY [Miners' safety lamps] 13,892/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: MAXWELL [Squirrel-cage induction motors] 4,871/11; SIEMENS SCHUCKERTWERKE GES. [Cooling of rotors] 5,247/11.

Electrochemistry: ELEKTROCHEMISCHE WERKE GES. [Synthetic production of endothermic compounds] 5,281/11 and [Synthetic production of ammonia] 5,282/11.

Telephony, &c.: SIEMENS & HALSKE A.-G. [Automatic telephone exchanges] 2,733/11; FAIELLA [Telegraphic systems] 4,920/11.

Miscellaneous: BUCHERT [Apparatus for coating articles with insulating compound] 4,185/11; FÉRY [Electric clocks] 4,889/11.

The following amended Specification can now be obtained.

SCHERL [Gyroscopic stability mechanism] 27,590/09.

Opposition to Grant of Patent

24,115/09. **Time Lag Device for Circuit Breakers.** G. ELLISON. This patent has been allowed in spite of opposition. The specification was abstracted in ELECTRICAL ENGINEERING, Dec. 15th, 1910, Vol. VI., p. 796.

Amendment

18,909/05. **Electric Welding of Sheet Metal.** A. F. RIETZEL. With certain exceptions, this specification has been amended as desired by the owners, Pontelec Welding Patents, Ltd. An abstract of the patent and the proposed amendments were given in ELECTRICAL ENGINEERING, Dec. 22nd, 1910, Vol. VI., p. 812.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

8,376 of April 1st, 1897. **Magnetic Separators.** G. KENTLER and F. STEINERT. The material is carried up the ascending side of a wheel or belt of magnetic poles, and the current of each electromagnet is continuously switched on and off so as to shake up the particles of iron as they tumble from one magnet to another, thus causing particles of non-magnetic matter to be mechanically separated from the iron particles.

8,663 of April 5th, 1897. **Johnson-Lundell Field Winding.** A. HOLMES (*E. H. Johnson and R. Lundell*). This patent covers the field construction of the well-known Johnson-Lundell motor, in which a single field coil is arranged round the two pole pieces in such a manner that the armature can be removed without disturbing the field coil.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: W. WHITNEY [Electrodes containing titanium, &c.] 26,917/04; J. HÄRDÉN [Electrode composition] 26,919/04; W. S. WEEDON [Electrode composition] 26,922/04.

Electric Ignition: A. ECKSTEIN and H. J. COATES [Ignition system for internal combustion engines] 26,527/04.

Electrometallurgy, &c.: O. FRICK [Induction furnace] 25,771/05.

Switchgear, &c.: R. H. KNIGHT and L. NAGEL [Wiring-conduit joints] 25,669/05.

Telephony, &c.: C. J. and F. X. BELIN [Photo-telegraphy with selenium cells] 26,586/04; S. EISENSTEIN [Wireless telegraphy] 26,696/04.

Traction: C. H. WILLIAMS [Brake shoes] 15,672/05.

Miscellaneous: J. MCINTYRE [Induction coil trembler] 21,834/05; W. SIMPKIN and J. B. BALLANTYNE [Magnetic separator] 25,748/05.

DIAL FUSES

THE Electrical Co., Ltd. (122–124 Charing Cross Road, W.C.), have introduced a system of non-interchangeable cartridge fuses and fittings to which the above name has been given. There are two types; in the "Dial A" fuses (for 2 to 25 amps.), the non-interchangeability depends both on the diameter and the length, and in the "Dial B" type (from 2 to 100 amps.) on the diameter only. The construction of the A type is shown in fig. 1, where the various parts of the

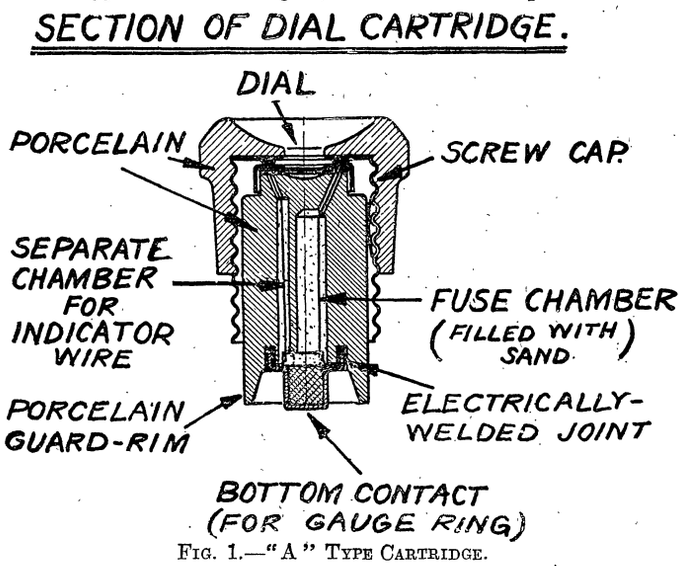

FIG. 1.—"A" TYPE CARTRIDGE.

cartridge are clearly shown. The bottom contact fits into a gauge ring forming part of the socket, and is of varying diameter, according to the capacity of the fuse. The upper contact is made by the screwing home of the cap, which carries a thread similar to that of an Edison screw lamp-holder. The complete cap, cartridge, and gauge ring of one of the B type fuses is shown in fig. 2. The principal difference is in the shape of the gauge ring and lower contact pin. The bases are made in a variety of forms, and the lower con-

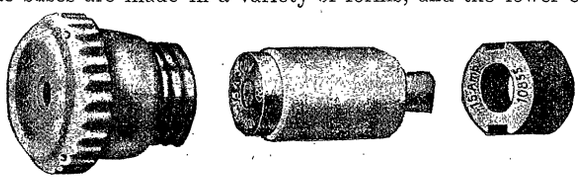

FIG. 2.—"B" TYPE CAP, CARTRIDGE, AND GUARD-RING.

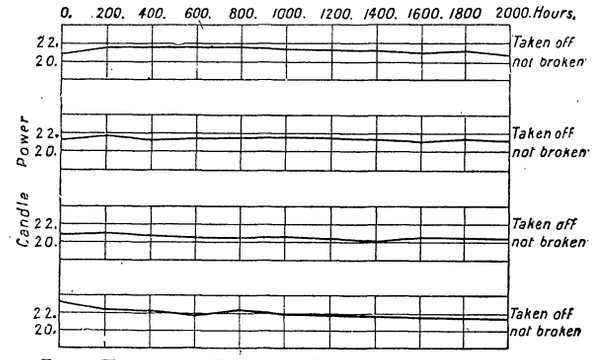

tact is fully protected by the soapstone gauge ring by which it is surrounded. The cartridges vary in colour according to the voltage. The actual fuse wires are of silver, in a chamber filled with sand, and the cartridges have been proved never to crack or explode on blowing, and the sand prevents a conducting film of silver being formed upon the inside surface. A fine constantan wire, in parallel with the main fuse wire, visible in the head of the cartridge, acts as an indicator whether the fuse has blown. The whole of the details seem remarkably well thought out, and a good example is presented of a system which offers some undoubted advantages as to safety.

THE LIFE OF METAL FILAMENT LAMPS

A GOOD deal of uncertainty has hitherto existed regarding the useful life of metal filament lamps, and many electrical engineers have regarded as extravagant the statements occasionally made to the effect that the life of a tungsten lamp was from 1,500 to 2,000 hours. In the first catalogue of metal filament lamps published some years ago by the Edison & Swan United Electric Light Co., Ltd., their life was stated to be about 1,000 hours. That this estimate was conservative has been known for some time, and in many instances these lamps have had a life some three or four times as long as the figure mentioned. So far back as 1909 it was announced that one of their metal lamps had burned for 5,880 hours.

The question has had further light thrown upon it by the series of independent tests on metal filament lamps recently carried out by the Westminster Electrical Testing Laboratory, of York Street, Westminster.

Four lamps made by each of fifteen makers were tested, and were not specially selected for the purpose, but were ordinary commercial lamps of 25 c.p. made for use on 200 volts. The curves given herewith of the four Ediswan lamps, which have been sent us by the Edison & Swan United Electric Light Co., Ltd., are of extreme interest, as it will be seen that not only were all these lamps still intact when taken off the test, but also that the candle-power of each

LIFE TESTS OF EDISWAN METAL FILAMENT LAMPS.

lamp is represented as practically a straight line, showing that the light given initially was maintained throughout the run.

The total watts taken by the lamps and the watts per candle-power also remained practically constant throughout the run.

CALCULATIONS OF MOTOR HORSE-POWER AND CURRENT

AN ingenious rotary cardboard device for making rapid estimates of the horse-power output or current input of either alternating-current or direct-current motors has been sent us by the Sandycroft Foundry Co., Ltd. (Sandycroft, near Chester), the manufacturers of the well-known Hunt "cascade" multiple-speed induction motors. The device is called the "Sandycroft Power Calculator," and consists of a carboard base cut in the form of an induction motor and provided with circular scales of volts and horse-power. A disc with circular scales of amperes, efficiency, and power factor is pivoted on this, and any calculation can be made by means of a single setting. The device is patented by Messrs. M. W. Ellis and T. M. Dutton. To find h.p., the amperes are set against the volts, and the h.p. is read against efficiency. In the case of A.-C. motors, it is read against a figure denoting efficiency × power-factor. To find the current, the efficiency or efficiency × power-factor is set against h.p., and the current is read opposite the volts.

CORRESPONDENCE

ELECTRICITY METERS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Although the Paper read last week before the Institution of Electrical Engineers on the subject of electricity meters is perhaps one of the most important contributions on the subject that we have had for some years, it is a pity that the experience of the authors has apparently been limited to a few types of meters which are not altogether representative of the latest and most up-to-date practice.

With regard to commutator ampere-hour meters, we must reject the curve of accuracy given as not applying to the better-class makes of ampere-hour meters, in which we include our own, and which are not more than 5 per cent. slow on 1-20th load, and are accurate within 2½ per cent. from 1-10th full load. In connection with continuous-current commutator watt-hour meters, whilst the authors recognise the fact that the most satisfactory is the Thomson type of meter, they object to the small diameter commutator, presumably owing to insulation difficulties which have been their experience. The efficient insulation of the commutator on a meter is always a difficult matter, whatever the diameter may be, but in our types B. E. R., &c., the commutator dimension is reduced to 2½ millimetres, and practically perfect insulation is obtained by insulating the whole frame, to which the movable element is fixed, from the base, in addition to insulating the commutator itself. The advantages gained by the use of a small diameter commutator in regard to friction and wear can only be secured where the armature coils are few, three in the case of the meter mentioned.

It appears to be a common fallacy that three-coil armatures give a very fluctuating torque, but actual tests show that this is only true *cum grano salis*, at least in the case of Simplex

Hosted by Google

meters. The constructional advantages of such armatures are obvious, and faults can be easily localised and remedied.

The easily removable armature is another feature which has been made use of for some considerable time in these types of meters. The authors of the Paper make mention of a removable spindle as being found in only one type of meter, but we should like to mention that we have supplied for some considerable time in all meters over 50 amperes a movable foot-step bearing ring; the bearing and pivot may be easily removed by hand without the use of any special tool, and may be as easily replaced, the armature locking automatically when the bearing is removed.

The objection raised by the authors to induction type a.c. meters on account of low torque and inaccuracy together with uncommon wave form, may apply to some classes of meters which have come under their notice, but in a well-designed a.c. meter, such as we claim for the Simplex type, 8–10 C.M.G. is obtained in single-phase meters (in polyphase meters considerably more), which, taking into consideration the absence of commutator friction and a light moving element, is certainly a distinct improvement on the old Thomson meter. The latter type might have developed 30 C.M.G., but this is discounted by the heavy weight of the moving element, the comparatively high speed, and, last but not least, commutator friction; these disadvantages contribute to make the meter inferior to a good induction meter.

With regard to variations in accuracy through wave form, the authors possibly lay undue stress upon this point, since the wave-forms instanced by them, which they admit were artificial and with difficulty obtained, cannot be said to represent actual service conditions. The testing of polyphase meters with single-phase current is now insisted upon by the Board of Trade, and all such meters as approved by them must be tested under these conditions. Our polyphase meters are built on this principle. Intersection between the two or three single-phase elements has been completely eliminated in the Simplex meters, and, of course, the breaking flux of the shunt circuits is fully considered when the meters are being calibrated.

Incidentally we should like to point out that we have had installed in our testing laboratory for some considerable time a set as mentioned by the authors on page 30B, and which they refer to as the "ideal set."

Yours faithfully,
SIMPLEX CONDUITS LIMITED.
Meter Department.

Garrison Lane, Birmingham.
March 28, 1911.

SOLDERED ALUMINIUM JOINTS

A NEW solder for aluminium has been brought to our notice by the Vacuum Engineering Co., Ltd. (24 South Moulton Street, W.), and, in view of the value to the electrical industry of an efficient solder for this metal, we decided to make some joints with its assistance. The Company assisted us in carrying out this intention, and we are also indebted to Messrs. Evershed & Vignoles, Ltd., for the loan of a "Ducter" for measuring the resistance of the joints. Our experience in using this beautiful instrument for a practical purpose fully confirms the high opinion which we had formed of it when it was first shown to us. A special flux is employed, which is in the form of a white powder, melting at a comparatively low temperature; it appears to clean the surface of the aluminium, at the same time forming a sufficient quantity of metal upon it to take the place of "tinning" in ordinary soldering, and even to join thin sheets of aluminium together without aid of the solder itself. The solder supplied takes readily to the surface cleaned by the flux, at a temperature slightly higher than the melting-point of the flux, and a joint in a stranded cable can be sweated up solid by pouring the solder through it exactly as in the case of a copper joint, although the solder does not "take" quite as smoothly as tin to copper.

Three simple twisted straight-through joints were first made with aluminium wire 0·087 in. diameter, some of them twisted less tightly than others. Before soldering, the resistance of a four-inch length of wire, including the joint, varied in the three cases from 40,000 to 130,000 microhms (·04 to ·13 ohm.). After soldering, the resistance was in each case 50 microhms (·00005 ohm.), which was also the resistance of a piece of wire of the same length without a joint, and the resistance was quite steady, showing that a thoroughly good electrical contact had been obtained.

In two cases the wires were simply immersed in the molten solder, and in the third case a soldering iron was used. The next test was to cover the ends of a short piece of 19/·087 aluminium cable (equivalent to 0·075 sq. in copper) with the flux, and to sweat them by dipping them into the solder. On sawing off the ends it was found that all the interstices between the individual wires had been filled, and the ends showed almost a solid section. The resistance of the cable was then measured, and it was found to be slightly less than the calculated value.

A tight "married" joint was next made in this cable, the inner core of seven wires being butted. The resistance of a 9-in. length of cable, including the joint before soldering, was 275 microhms, and after soldering was 85 microhms, while the resistance of a 9-in. length of the same cable, without a joint but with the ends soldered up solid, was 77 microhms.

Finally, a sleeve joint connecting two pieces of 37/·078 aluminium cable (corresponding to about 0·125 copper) was made and tested. A piece $16\frac{3}{4}$ in. long with the ends soldered solid measured 85 microhms, and a piece $9\frac{1}{2}$ in. long 40 microhms, the sum of the two being, therefore, 125 microhms. The two pieces were butted together and a piece of sheet aluminium $3\frac{1}{4}$ in. long wrapped round so that a $\frac{1}{4}$ in. gap was left along its length. The joint was then heated over a bunsen flame and flux and solder put in between the ends of the cable, which were drawn apart a little. When the solder had been molten a minute or so the ends were butted together and the joint allowed to cool. The resistance from end to end was then 122 microhms, which conclusively proves that a perfect electrical contact was obtained.

We are assured that no corrosion takes place with this solder. Two pieces of aluminium strip soldered together some three months ago have been in London tap-water since then, and the joint shows no signs of corrosion.

Tests made on joints with sheet and cast aluminium showed the mechanical strength to be highly satisfactory, the aluminium tearing or breaking at points other than where the joint was made.

PARLIAMENTARY INTELLIGENCE

MUNICIPAL WIRING.—The Luton Corporation Bill, which was passed by the Local Legislation Committee of the House of Commons last week, contains a clause giving the Corporation powers to undertake the wiring of premises and provide fittings, &c., on condition that this work is not carried out direct by the Corporation.

LONDON UNITED TRAMWAYS.—This Bill, which gives the Company twelve months' extension of time within which to construct a tramway between Kew Bridge and Richmond, was passed by the Unopposed Committee of the House of Commons on Thursday.

PROGRESS OF ELECTRICAL BILLS.—The London Electric Railway Bill and the Metropolitan District Railway Bill were read a third time in the House of Commons on Friday.

THE LANARKSHIRE TRAMWAYS.—This tramways Provisional Order, which has been under consideration in Scotland during the past week, has been withdrawn owing to the Commissioners proposing to insert a penalty clause should the proposed tramways not be completed within a specified period. The Order also contained powers for running trolley omnibuses.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

STREET LIGHTING.—An attractive booklet entitled "Street Lighting by Osrams," has been issued by the General Electric Co. (67 Queen Victoria Street), in which are collected together a quantity of data regarding the success that street lighting by Osram lamps has met with in Marylebone, Hampstead, Shoreditch, Wimbledon, Hammersmith, Glasgow, Nuneaton, Croydon, and numerous other localities, where they have been adopted extensively. A number of extracts from our own columns and those of our contemporaries are given and the object-lesson is rendered all the more forcible by the inclusion of an effective series of night photographs.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

SUPPLY ADVERTISING.—A copy has been sent us of a leaflet that is being issued in the Loughborough district by the Electricity Department, which puts the case for electricity in preference to gas in an attractive way, and gives particulars of a deferred payment system for wiring on the basis of 9½d. per point per quarter for three years.

CORONATION ILLUMINATIONS.—The Sun Electrical Co. (118–120 Charing Cross Road, W.C.) have now issued their complete Coronation illumination catalogue, which deals with a very extensive range of material for the purpose. Two different forms of "Suncolite" strip are included, and a quantity of decorative accessories for combining with these systems. A miniature strip is also listed which is easily made up into letters and devices. There are some very attractive designs, including illuminated transparencies and adaptations of the signs for which the firm is famous. A well-chosen selection of switches, fuses, plugs, connectors, &c., complete this useful publication.

DYNAMOS.—The new small continuous-current dynamo list

Hosted by Google

of the Union Electric Co., Ltd. (Park Street, Southwark, S.E.), dealing with machines up to 30 kw., gives, in addition to the very well-arranged tables of sizes and outputs, a complete technical specification of the machines with numerous illustrations of the different forms they take with different degrees of enclosure, and of details of their parts.

WIRES AND CABLES.—After the excellent paper cable and other lists issued by Messrs. Aubert Grenier & Co. (68A Lincoln's Inn Fields, W.C.), we naturally expect a well-arranged catalogue in their new list of V.I.R. wires and cables just issued, and in this we are not disappointed. The tables are clearer to read than many, and the use of red for the prices is an advantage. Flexibles, bell wires, motor-car ignition cables, and aerial wires and cables are also dealt with.

ELECTRIC LIFTS.—A great deal of interesting information is contained in the sumptuous new catalogue relating to electric lifts, which has been produced by Messrs. R. Waygood & Co., Ltd. (Falmouth Road, S.E.), who, it may be remarked, claim to have been the first manufacturers of electric lifts in this country. Numerous forms of passenger lifts are illustrated, and these now run at speeds up to 400 ft. per minute. The mechanical details are also fully described and illustrated, with its worm driven drum or sheave, special electrical and mechanical safety appliances, and simple control gear. The last-mentioned can be of the car switch or push-button pattern, either fully or semi-automatic. Both alternating and continuous-current equipments are described, and among the large lift installations carried out by the company which are chosen for extended mention in the catalogue are those of the Royal Liver Building, Liverpool, and the new King Edward Post Office Buildings, the latter of which is an example of a three-phase equipment. Goods lifts are also dealt with, particularly those for motor-cars, and a few illustrations of public lifts, lifts for liners, of which Messrs. Waygood have supplied a large number, and the gantry lifts at Messrs. Harland & Wolff's shipyard conclude this interesting publication.

METAL FILAMENT LAMPS.—A most attractive postcard has been produced by the British Thomson-Houston Co. (Rugby) for advertising the Mazda Lamp bearing the legend "The Mazda lamp for beautiful light," and depicting one of these lamps being admired by a lady even more beautiful than the light of the lamp.

HOLOPHANE REFLECTORS.—Messrs. Siemens Brothers Dynamo Works, Ltd. (Incandescent Lamp and Fittings Department, Tyssen Street, Dalston), have issued a list dealing with 14 new patterns of Holophane Reflectors specially adapted for household use. Many of these are of particularly good appearance, and we hope to publish illustrations of them at an early date. Another new publication is a card illustrating a chain suspension and gallery for "stiletto" holophane reflectors forming a very convenient pendant. The firm are willing to overprint quantities of this card free of charge for any electrical contractor on receipt of inquiry.

In our notice last week in this column headed electrical thermometers, we regret that the interesting series of instruments mentioned were attributed to the Leskale Co. The correct name of the firm is The Leskole Company, Palace Works, Enfield.

LOCAL NOTES

Australia: *Melbourne: Tramways.*—It is stated that the Victorian Government propose to purchase the Melbourne City tramways, the lease of which still has six years to run.

Beckenham: *Increase in Lighting Charges.*—A recommendation of the Lighting Committee to increase the charge for lighting by ½d. per unit in order to counteract the effect of metal filament lamps has been adopted.

Croydon: *Electricity and Tramway Profits.*—It is stated that a sum of about £17,000, taken from the profits of the electricity and tramway undertakings, will be paid over in relief of rates.

Glasgow: *Tramway Assessment.*—The Assessment Committee of the Glasgow Corporation has dismissed the appeal of the Tramways Committee against the assessment of the tramways. The Tramways Committee protest against being assessed on the full valuation of the tramways instead of one-fourth. The decision of the Assessment Committee is to be appealed against.

Larne: *Electric Supply Co.*—The Council are to have a report prepared regarding the purchase of the Larne Electric Light Works, Ltd.

London: *Fulham: Period of Loans.*—The Comptroller of the London County Council has suggested that the Fulham Council should, instead of accumulating a reserve fund for renewals, arrange for the reduction of the periods for the repayment of outstanding loans from forty-two to twenty years, which latter is now the usual period allowed by the L.C.C. The Finance Committee of the Borough Council recommend that this course be not adopted.

Hammersmith: Municipal Wiring.—The Electricity Committee recommend that a scheme for the supply on hire of wiring and fittings required for external lighting be adopted, the work being carried out by contractors.

Stepney: Trolley v. *Conduit Tramways.*—The Works Committee once again recommend the Borough Council to refuse its consent to the adoption of the overhead system in Burdett Road and Globe Road.

Morecambe: *Lighting Committee Resigns.*—A scheme by the Electric Light Committee for granting reduction to certain classes of consumers was objected to by the Council last week, and a resolution was moved appointing the chairmen of all the Standing Committees of the Corporation to meet in order to come to a decision. The position arose on account of the attitude of the members of the Gas Committee. The Electric Light Committee thereupon withdrew from the Council, and subsequently asked to be relieved of their duties. This, however, was ruled out of order, and the matter was allowed to drop.

Newcastle: *Tramway Profits.*—It is proposed to transfer £6,000 out of last year's profits to relief of rates. It was originally proposed to transfer £10,000, but this was objected to.

Northumberland: *Tramways.*—An expert is to be consulted with regard to the proposed municipal tramway service between Blyth, Bedlington, Ashington, and Newbiggin. Local opinion seems to favour trolley omnibuses.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Beckenham.—The Local Government Board have sanctioned loans of £2,000 for mains, £3,000 for services, and £1,000 for meters.

Bury.—The Local Government Board have sanctioned a loan of £72,170 in connection with the new generating station, and also for additional mains.

Handsworth.—The Electricity Committee require switchboard extensions, cables, feeder pillars, and overhead-tramways equipment. Particulars from the Town Clerk, or Messrs. Kennedy & Jenkin, 17 Victoria Street, London.

Ireland.—Tenders are invited by April 10th for generating plant, and also for wiring, at the Cavan College and Bishop's House. Consulting Engineer, Mr. A. E. Porte, 43 Dawson Street, Dublin.

Kettering.—A Local Government Board inquiry was held last week concerning a loan of £13,100 for electrical extensions.

London: *Battersea.*—The Finance Committee of the L.C.C. have sanctioned a loan of £1,400 for electrical extensions.

Bermondsey.—The Electricity Committee require three boilers, a steam dynamo, and condenser. Particulars from the Borough Electrical Engineer, and tenders by April 19th.

Hackney.—The Finance Committee of the L.C.C. have sanctioned a loan of £20,599.

St. Pancras.—Tenders are invited by April 12th for a motor generator and balancer. Particulars from the Electrical Engineer.

Rugby.—Tenders are invited for laying 5,000 yards of cable. The Electricity Committee also requires 5,500 yards of 3-in. Sykes stoneware troughing, 1,500 yards of stoneware covers, and 30 tons of refined Trinidad bitumen. Particulars from the Electrical Engineer, and tenders by April 7th.

St. Helens.—The Electricity Committee invite tenders by April 20th for a 1,500-kw. turbo alternator with condensing plant and switchgear. (See an advertisement on another page.)

Swanage.—Mr. F. Swarbrick, of Leigh, has been asked for further details of an electric lighting scheme which he has put before the Council.

York.—Tenders are invited by April 11th for the replating of the storage battery, and the supply of a reversible booster and switchboard.

WIRING

GREATER LONDON.

Rebuilding of Threadneedle Street Branch Post Office.

New branch Post Office at East Ham.

Proposed electric theatre at Eltham.

Twelve houses, Melrose Avenue, Croydon. Thirty-one houses, Kingscote Road.

Cinematograph theatre at 260–262 North End Road, Fulham.

Extensions to Nurses' Home at Infirmary, Archway Road, N. Architect, A. S. Snell, 22 Southampton Buildings, Chancery Lane, W.C.

PROVINCES.

Dover.—Theatre in Castle Place.

Edinburgh.—Charteris Memorial Church.—Alterations to Commercial Bank of Scotland, Northbridge. Architect, T. Forbes, 14 George Street.

Glasgow.—New theatre in Charles Street. Architects, George Alder & Sons.

Maidstone.—Additional wards at County Asylum.

Morley.—Pavilion at junction of High Street and South Queen Street. Architects, Howorth & Howorth, Bank Chambers, Cleckheaton.

Plymouth.—Barracks at Lambhay Green. Architect, T. R. Kitsell, Broad Street Chambers.

Southampton.—Cinematograph theatre in East Street.

Swindon.—Enlargement of head post office. H.M. Office of Works, London.

Wakefield.—Elementary School in Lawefield Lane. Architects, Messrs. Watson, Son & Ellison, Barstow Square.

MISCELLANEOUS

Blackpool.—Ten flame arc lamps are to be erected on the promenade.

London.—A quantity of meters, fuse switches, &c., are required for the Olympia Electrical Exhibition, 1911. (See an advertisement on another page.)

The Commissioners of H.M. Office of Works and Public Buildings invite tenders for three years' supply of electrical fittings and tubes. (See an advertisement on another page.)

St. Pancras.—Tenders are invited by April 12th for a supply of arc lamp carbons. Particulars from the Electricity Department, 57 Pratt Street, Camden Town, N.W.

Southend.—An inquiry was held last week by the Light Railway Commissioners into an application by the Council for considerable extensions of tramways.

TENDERS RECEIVED AND ACCEPTED

Beckenham.—The tender of Messrs. Lucy & Co. has been accepted for lead boxes, and that of the British Insulated & Helsby Cables, Ltd., for cut-outs.

Bombay.—The Oerlikon Co. has received an order for the equipment of a large cotton-spinning mill near Bombay, comprising three vertical-shaft three-phase generators of 900 h.p. each, together with the requisite switchgear, and 250 single-phase motors with automatic speed regulation for driving ring-spinning machines.

Croydon.—The tender of Messrs. Callender's Cable & Construction Co., Ltd., has been accepted for the supply of cables for the year to March 31st, 1912.

Grimsby.—The tender of Messrs. Crompton & Co. for a supply of electric motors for hiring out at £322 8s. has been accepted. The lowest tender was that of the Electrical Co., Ltd.; but as the difference in price was small, and a number of Crompton motors are at present working very satisfactorily in Grimsby, Mr. W. A. Vignoles, the Electrical Engineer, recommended the acceptance of Messrs. Crompton's tender.

Ipswich.—The following tenders have been received for a 1,000-kw. turbine driving two C.C. generators on the same shaft, with surface condenser, air and circulating pumps, &c.: Howden & Co., £4,541; alternative, Howden & Co., £4,800; Willans & Robinson, £4,756; alternative, £4,906; Brush Electrical Engineering Co., £4,950; Escher, Wyss & Co., £5,138; Richardsons, Westgarth & Co., £5,175; British Westinghouse Co., £5,195; alternative, £5,546; C. A. Parsons & Co., £5,320; alternative, £5,623; and A. E. G. Electric Co., £6,100. The tender of Messrs. Willans & Robinson at £4,756 is recommended for acceptance. This tender provides for Siemens dynamos.

The tender of Messrs. G. & J. Weit, Ltd., for a compound direct-acting steam feed pump, with a capacity of 6,000 gallons per hour, at £259 has also been accepted.

Leek.—The Lighting Committee recommend the acceptance of the tender of the Diesel Engine Co., Ltd., for a 220-kw. generating set (Crompton dynamo) at £3,570 10s.

London: *County Council.*—The tender of Messrs. George Wimpey & Co. at £26,409 10s. is recommended for acceptance for the road work on the Putney Bridge to High Street, Wandsworth, tramways.

Arrangements are being made with Messrs. Hadfield's Steel Foundry Co., Ltd., at £2,641 16s. and £1,387 respectively, for the special work required on the Battersea Park Road to King's Road, Chelsea, trams, and the reconstruction of the horse tramways in Highgate Road.

A contract has been entered into with the National Rail and Tramway Appliances Co., Ltd., for the supply of brake shoes to April, 1912.

Hammersmith.—The Works Committee recommend that 183 existing arc lamps be replaced by clusters of four or five 110-watt metal filament lamps. The annual charge by the Electricity Committee is to be £12 10s. for each column with five lamps, and £10 for each four-lamp column, instead of the existing charge of £20 per column for arc lamps. The cost of converting the lamps—namely, £752—is to be provided out of revenue. It is also recommended that all existing small arc lamps be converted into clusters of metal filament lamps as they wear out.

Wadebridge.—The lighting of the district has been divided between the Electricity and Gas Companies.

Watford.—The Council have accepted the tender of Messrs. Drake & Gorham, Ltd., for the alteration to street lanterns and the supply of metal filament lamps for three years.

APPOINTMENTS AND PERSONAL NOTES

A tablet has been unveiled at the Hackney Town Hall in memory of the Mr. H. W. Cox who died last year from the effects of his early work with X-rays.

The Hackney Electricity Committee recommend that the maximum salary of Mr. T. Dalby, Works Superintendent, be increased from £200 to £250 per annum. Mr. Dalby is at present in receipt of £200 per annum, and the new maximum will be reached by annual increments of £10. It is also recommended that the salary of Mr. E. Matthews, Testing Engineer, be increased from £130 to £160 by annual increments of £7 10s. It is further recommended that the salary of Mr. E. Wilkinson, Deputy Generating Engineer, be increased from £117 to £125 per annum.

Mr. W. G. Bond, who has been connected since 1899 with the British Electric Traction Co., has taken over the General Managership of the Traction and Power Undertaking operated by the Birmingham and Midland Tramways Joint Committee.

A switchboard attendant is required at Kilmarnock. (See an advertisement on another page.)

On the occasion of the appointment of Mr. W. Buchanan, late Senior Lecturer at Faraday House, to the Professorship of Electro-Technology in the Royal School of Mines, Transvaal University, his old pupils presented him with a pocket aneroid barometer. The presentation was made last Friday by Mr. F. de Lautour, foreman student.

The maximum salary of Mr. S. E. Britton, City Electrical Engineer at Chester, has been increased from £500 to £600 per annum.

Obituary.—We regret to announce the death last week in Chalmers Hospital, Edinburgh, of Mr. H. G. Young, Engineer and Manager of the Bo'ness Electricity Works. Mr. Young had been with the National Electric Construction Co. for about seven years, and was previously Assistant Manager of the Musselburgh tramways.

The Electrical Trades Benevolent Institution.—The annual general meeting of the above was held yesterday at the Hotel Cecil. The annual report records well-maintained activity during the past year, although there was a slight falling off in the receipts. Every case of relief, however, was satisfactorily dealt with. The festival dinner held early in the year added to the funds of the institution, and on the realisation of the surplus fund trust of the Olympia 1905 Electrical Exhibition, a further £382 will accrue to the funds. Mr. W. Davenport has retired from the secretaryship, and Mr. F. B. O. Hawes has been appointed in his place. The assets of the institution (including £180 cash at bank) now amount to £2,466. Grants were made during the year totalling £27 12s.

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £56 15s. to £57 5s. per ton (last week, £57 to £57 10s.).

Liquidations.—A special meeting of the contributories of the Uxbridge and District Electric Supply Co., Ltd., was held on Thursday to consider a scheme for the arrangement of the Company's affairs. It provides for the payment of the first and second mortgage debenture-holders with interest, and, by means of an issue of £75,000 debenture stock guaranteed by Callender's Cable and Construction Co., Ltd., to satisfy the remaining creditors. A rearrangement of capital is also provided for in the scheme, which was unanimously accepted.

Mr. Justice Swinfen Eady on Tuesday made a compulsory winding-up order against the British Tungsten Lamp Co., Ltd., of Liverpool, on the application of two creditors.

The Automatic Trolley Head Co., Ltd., is to be wound up voluntarily. Mr. H. S. Foster, 82 Victoria Street, Westminster, S.W., is liquidator.

Dissolution of Partnership.—The partnership between A. H. Robinson, W. H. Horsfall, and E. B. Mulliner, trading as Robinson & Mulliner, Consulting Engineers, Liverpool, has been dissolved.

Bankruptcies.—The creditors of the North British Electric Power Syndicate, Ltd., are requested to send in particulars of their claims to Mr. Andrew Wood, 695 Salisbury House, London Wall, E.C., not later than April 15th.

United States Metallic Packing Co., Ltd.—This firm have now opened a branch office at 2 Collingwood Street, Newcastle-on-Tyne, in charge of Mr. H. B. Plummer.

Holophane Reflectors.—Holophane, Ltd. (12 Carteret Street, Queen Anne's Gate, S.W.), are now in a position to supply the trade with their new line of "Residence" holophane reflectors, which, while maintaining the optical efficiency of the holophane system, introduce new artistic features of design.

Pirelli & Co., Ltd.—A report has been published by a contemporary that Messrs. Pirelli & Co., of Milan, are about to build works in this country. We are in a position to state that this is incorrect, and that the firm in question have no immediate intention of establishing a cable factory here.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Isle of Wight Electric Light & Power Co.—After meeting debenture interest and preference dividend, there is a sum of £5,806 available as profit for 1910. The directors recommend that £3,500 be added to renewals fund, and £1,000 to reserve, carrying forward £686.

Madras Electric Tramways.—A dividend of 2 per cent. is declared upon the deferred ordinary shares for 1910, and 2½ per cent., in addition to 1 per cent. out of the surplus profits, on the preferred ordinary shares, making 5½ per cent. for the year.

Metropolitan Electric Tramways.—Dividend at the rate of 5 per cent. per annum on the ordinary shares for 1910.

Bell Telephone Co. of Canada.—An issue of $1,250,000 5 per cent. bonds has been offered during the week.

Durham Collieries Electric Power Co.—There was a loss of £9,300 for 1910. This unsatisfactory position has resulted in the directors calling in an independent electrical expert to consider the position, and look into affairs on the spot.

South London Electric Supply Corporation.—At the annual meeting last week, Mr. J. Atherton said that the present rate of progress of the undertaking was such that, if it were maintained, extensions of plant will have to be considered at the end of the present year.

British Aluminium Co.—The report for 1910 shows a profit of £125,063, but the profit in respect of the period prior to the date of the incorporation of the company is £34,606, leaving £90,457, which, after adding interest on deposits, &c., is increased to £91,865. The sum of £25,000 is transferred to depreciation, £21,000 to debenture interest, and, after meeting various other charges, the sum of £4,943 is carried to reserve. The report states that, although the output for last year was greater than in the previous year, the company's works were not operated to their full capacity, but the demand for aluminium was increasing satisfactorily.

Lancashire Electric Power Co.—Mr. H. F. Parshall stated, at the annual meeting on Thursday, that another generating set was being installed to meet the increasing demand, and arrangements have been completed for the issue of £150,000 prior lien bonds.

South Wales Electrical Power Distribution Co.—The report for 1910 states that steady progress has been made by the Treforest Company, the total units sold being 1,715,226 in excess of those sold in 1909, and the result of the year's working of this Company was to leave a small profit after meeting prior lien debenture interest, &c. The Treforest Company have found it necessary to order a second turbine set to meet the increasing demand. As the whole of the expenses in connection with the South Wales Company are now being borne by the Treforest Company, the directors present no revenue account.

Folkestone Electricity Supply Co.—After meeting debenture interest and preference dividends, there was a profit of £8,949 for 1910. A dividend at the rate of 6 per cent. per annum for the year has been paid on the ordinary shares, £5,000 carried to depreciation fund, and £349 carried forward.

Vickers, Sons & Maxim.—The annual meeting was held at Sheffield on Tuesday, Mr. Albert Vickers presiding. The proceedings were quite formal, the Chairman commenting upon the satisfactory nature of the year's working, and looking forward to a still further improvement in the current year. The recommendation to change the company's name to "Vickers" was carried unanimously.

The Electrical Trades' Benevolent Institution.—This year's Festival Dinner of the above will be held at the Hotel Cecil on Wednesday, April 26th. Lord Justice Fletcher Moulton has consented to preside.

The National Electrical Manufacturers' Association.—At a meeting of this Association on Tuesday, April 25th, at 8 p.m., a Paper will be read by Mr. L. Joseph on "Foreign as Compared with Home Industrial Finance." The meeting will probably take place at the Institution of Electrical Engineers.

Wireless Telegraph Notes.—The report of the Australian Wireless, Ltd., for 1910 states that a contract has been received from the Commonwealth Government for the erection of high-power wireless telegraph stations at Pennant Hills and Fremantle. The New Zealand Government have also accepted the Company's tender for two high-power stations and five ship stations.

The high-frequency generator designed by Dr. R. Goldschmidt for wireless work consists of a machine similar in construction to a simple single-phrase induction motor. The stator winding is supplied with continuous current, and the rotor, which has a short-circuited winding, is driven by a motor. The magnetic field of the stator induces an alternating current in the rotor, and the alternating field of the current induces currents of double the frequency in the stator winding, which is short-circuited by a condenser. A choking coil prevents any alternating current reaching the battery. This induction between the two elements is continued theoretically to an infinitely high frequency, and by suitable tuning only that current of a certain desired high frequency can be obtained in the external condenser circuit connected across the stator winding. A 12½-kw. machine giving a frequency of 30,000 cycles per second corresponding to a wave-length of 10,000 metres has been constructed by C. Lorenz A.-G. of Berlin, and has given every satisfaction.

According to the *Board of Trade Journal*, the Russian Council of Ministers have decided to erect a wireless telegraph station on the banks of the Cara Sea, Siberia.

Telegraph Traffic and Movements of Cable Ships.—The El Arich route between Eskichechir and Biledjik was down on 21st inst., and on the same date fire disabled the offices at Petropavlovsk.—The French Administration has followed suit in the reduction of rates *viâ* Brest-Dakar-Norouba to places in Brazil brought about by German competition.—The El Arich route was working again on the 22nd inst., which also saw the failure of the cable between Bathurst and Bissao.—On the 25th inst. the Lemnos-Salonica cable ceased working for a short while, and the Zante-Corfu cable was restored to working order. The cable between Candia and Sitia failed on the same day. On the 27th inst. the cable between Constantinople and Odessa became interrupted, so that the Eastern Company has a little repair work in hand now.—The recent stormy weather played havoc with land and telephone lines in Kent, etc., but disorders were soon put right.—Lines were down on the 27th between Inhassunge Vicente and Chinde Inhangombe in the district of Quelimane. On the same date telegraphic communication between Ceiba and Trujillo in Honduras was again in working order.—The c.s. *Minia* of the Anglo-American Telegraph Co. recently made an attempt to repair the old 1874 cable of the Company, but failed owing, it is believed, to ice.—The *Contre Amiral Caubet* repaired the St. Pierre-Cape Cod cable of the Compagnie Française des Cables Télégraphique, and returned to port. She went into dry dock owing to damage caused by ice.

SUMMARY

Our monthly supplement on Electrical Engineering in Mines is included in this issue. It opens with an article discussing the limitations in the use of electricity in mines proposed in the Bill now before Parliament. A note is given on the inquiry into the Hulton Colliery explosion, and a discussion on the relative merits of electric power and compressed air is reported. An abstract of a communication dealing with the design of electric winding plants with balance ropes is also included, and among other articles are a description of the Winhey leakage detector and a new safety switch and plug. Some recent mining switchgear is also illustrated, and a report is given of a Home Office prosecution in Scotland. The more important electrical mining patents published during March are abstracted.

A letter from a well-known metal filament lamp firm criticises some particulars of tests of another make of lamp published last week. Another correspondent deals with aluminium solders. (Page 175.)

The subject of electricity meters is taken up by several correspondents. Messrs. Ferranti, Ltd., defend the mercury type, a station engineer gives his experiences, Mr. Paterson of the National Physical Laboratory discusses the testing of three-phase meters, and Mr. Schattner explains how the defects in the earlier commutator meter have been overcome. (Page 175.)

Major Pringle, in his report on the Hawes Junction accident, says that the fire originated without doubt in gas lighting equipment on the train, and expresses the opinion that, with every possible precaution, electric lighting will remain the safer method. (Page 176.)

The petition of the Lodge-Muirhead Wireless Syndicate for an extension of term of the Lodge patent covering the use of an inductance in the sending aerial to produce a prolonged series of tuned waves, and of a closed receiving circuit which can respond by resonance to a series of feeble impulses, is now before Mr. Justice Parker in the High Court. (Page 176.)

The first section of the Swedish State Railway System to be converted to electric traction is the 80-mile single-track line between the mining centre of Kiruna and Riksgränsen on the frontier of Norway. Power will be supplied from a water-power station, some 120 miles distant from the middle of the line, over a 50,000-volt single-phase transmission line. Current will be supplied at 15,000 volts, 15 cycles, to heavy locomotives, with commutator motors of the compensated series type. Besides a few passenger trains, eight heavy ore trains, each consisting of 40 ore trucks and two locomotives, and weighing 2,050 tons, will run daily in each direction. (Page 177.)

Prof. J. A. Fleming, during a course of Cantor Lectures at the Royal Society of Arts, dealt with the subject of electric furnaces, describing the different patterns, and the various manufactures in which they are employed, namely, the production of carborundum, aluminium, calcium carbide, artificial fertilisers, and the different special steels. A report of these lectures is given under "Electrometallurgy and Electrochemistry" together with some notes on several methods for the production of zinc in the electric furnace. (Page 178.)

At a meeting of the Farmers' Club on Monday, Mr. J. H. Priestley, lecturer in botany at the Bristol University, gave an interesting lecture on electricity in agriculture. He described the experiments with overhead wires on the Lodge-Newman system at Evesham, and then dealt with the application of Cooper-Hewitt lamps in greenhouses. At a distance of four feet from the lamps it is found that there is a distinct acceleration of growth, accompanied by one or two peculiar characteristics. (Page 179.)

The purchase price of the Cavehill & Whitewell tramways has been fixed at the high figure of £55,155, and the Belfast Corporation suggest an appeal.—The City of London Corporation has at last approved a route for the main to link up the two stations of the County of

Hosted by Google

London Electric Supply Co.—It has been found necessary to anchor all the rails of the L.C.C. tramways laid down under the original scheme.—Difficulties are being met with by the promoters of the Brighton-Worthing tramways scheme through the absence of consents of road authorities. (Page 180.)

ADDITIONAL mains are required at Accrington and Stoke-on-Trent; new batteries at Barnstaple and York; new generating plant at Luton, Torquay, and Worcester; traction battery, reversible booster, and switchgear at Wrexham; a 350-kw. static transformer at Manchester, and a 1,500-kw. turbo-alternator at St. Helens. Hornsey Council require flame arc lamps; Manchester Corporation, tramway poles; and Australian Postmaster-General, 10,000 telephone protectors. A telephone system is to be installed in Korea. (Page 180.)

THE proposals of the Metropolitan Electric Supply Co. to purchase the Acton Council's electricity undertaking have been passed by a House of Commons Committee. The Central London Railway Bill, which will enable through trains to be run from Liverpool Street to Ealing, has also been passed. In passing the Bill of the Winchester Corporation for purchasing the local Electric Light & Power Co., a House of Lords Committee inserted the Northumberland clause. (Page 182.)

AMONG the specifications published by the Patent Office on Thursday last was one by C. J. Beaver for a cable with two layers of armouring, between which is a layer of fireproof material to prevent external arcing.—A method of regenerative control with series motors, in which the fields have an additional supply from a battery, is described by the Johnson-Lundell Electric Traction Co.—A patent for an electric advertising sign, in which transparent devices are exhibited successively, has been granted, in spite of opposition.—A patent relating to the Berry transformer expires next Thursday, after the full life of fourteen years. (Page 183.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, APRIL 6TH.

National Electrical Manufacturers' Association.

2.30 p.m. Council Meeting at Balfour House, Finsbury Pavement, E.C.

Institution of Electrical Engineers.

8 p.m. "Wireless Telegraphy Working in Relation to Interference and Perturbations," by J. E. Taylor.

Institution of Electrical Engineers: Dublin Section.

8 p.m. At Royal College of Science.

FRIDAY, APRIL 7TH.

Royal Institution.

9 p.m. Evening Discourse:—"A New Method of Chemical Analysis," by Prof. Sir J. J. Thomson, F.R.S.

SATURDAY, APRIL 8TH.

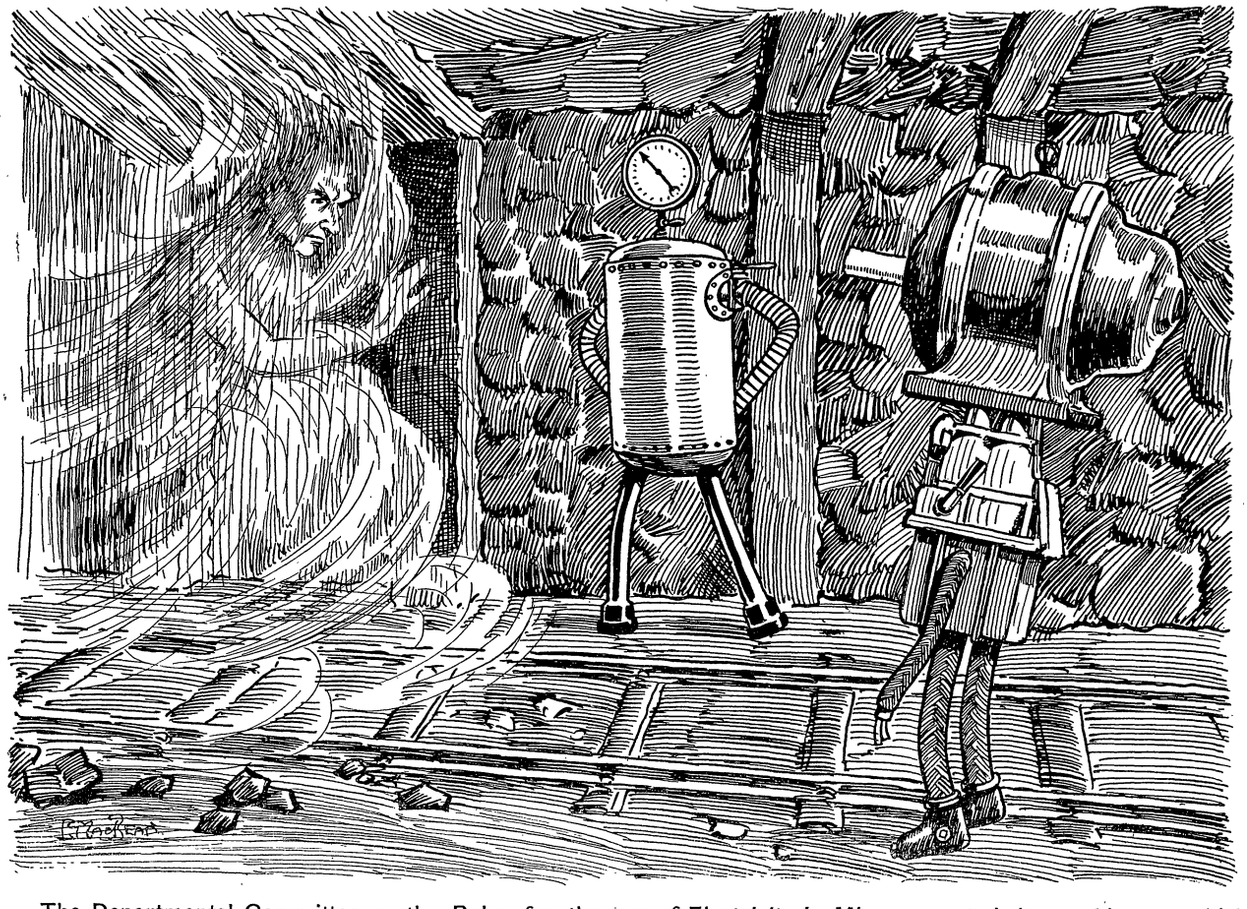
Birmingham and District Electric Club.

7 p.m. At Colonnade Hotel. Ladies' Night.

TUESDAY, APRIL 11TH.

Institution of Electrical Engineers: Glasgow Section.

8 p.m. At 207 Bath Street.



WEDNESDAY, APRIL 12TH.

Mining Institute of Scotland.

5.30 p.m. At 39 Elmbank Crescent, Glasgow. (1) "Some Considerations Affecting the Installation of Power at Collieries," by F. Anslow. (2) "Recent Progress in Mining Switchgear," by G. Stevenson. Also discussion on New Mines Bill.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. At Victoria Embankment. "The Present Position of Electric Traction on Main Lines in Europe," by J. B. Sparks.

The Departmental Committee on the Rules for the use of Electricity in Mines reported that accidents could be avoided in all cases in which electricity is used if the best present-day practice is complied with. But, as it is difficult to ensure this, they suggested that electricity should be prohibited where there is daily or frequent occurrence of inflammable gas. The Government have brought in a Bill giving effect to this recommendation. In cases in which inflammable gas may occur in quantity, although not normally present, electricity is to be permitted, but special precautions are to be observed.

ELECTRICAL ENGINEERING

IN

MINES

Correspondence on any of the subjects dealt with in this Supplement is cordially invited from our Readers.

The Editor is willing to insert letters over a *nom de plume*, but Correspondents should send their full names and addresses in all cases.

Letters should be addressed, "THE EDITOR, ELECTRICAL ENGINEERING, 203–206 Temple Chambers, London, E.C.," and should reach this office by the 21st of the month.

Correspondents are requested to write on one side of the paper only.

PROPOSED LIMITATIONS OF THE USE OF ELECTRICITY IN MINES

THE new Coal Mines Bill, which has passed its second reading in the House of Commons, contains one important clause (No. 60) relating to the use of electricity in mines. This reads as follows:—

(1) Electricity shall not be used in any part of a mine where, on account of the risk of explosion of gas or coal dust, the use of electricity would be dangerous to life, and if the owner of a mine, on being required by an inspector of the division not to use, or to desist from using electricity in the mine or any part thereof on such ground as aforesaid, refuses to do so, the question as to the application of this section to the mine or part thereof shall be settled in manner provided by this Act for settling disputes.

(2) The use of electricity in any mine shall be subject to general regulations under this Act.

It will be noted that this clause is identical with Rule 1 of the proposed new special rules prepared by the Special Committee, and reviewed in ELECTRICAL ENGINEERING IN MINES, March 2nd, 1911, p. xvii., and it is essential that the intentions of the Committee should not be misunderstood, for the meaning of the clause as it stands is not sufficiently definite, and the wording should certainly be modified when the next stage of the Bill is reached. In their report the Departmental Committee says:—

The Committee knows of no place below ground in which electricity is in use to-day where both kinds of accident would not be avoided if the best present-day practice as regards construction and maintenance were complied with . . . , but as it is difficult absolutely to insure continuous and universal compliance with the best present-day practice, the Committee is of opinion that there are parts of some mines from which electricity should be excluded altogether, and that in this respect, therefore, the existing rules require amendment. The daily or frequent occurrence of inflammable gas in any place in quantity detectable by the ordinary safety lamp in use at the mine, would make that place one to which prohibition should apply. On the other hand, in the opinion of the Committee, prohibition is not required where gas is seldom found, or where from experience in the neighbourhood, and from all the evidence available, it is likely to be of rare occurrence: provided good work and proper maintenance are insured so as to obviate as far as is practicable the risk of open sparking.

To meet this second class of conditions, the Committee have recommended the special precautions (referred to in our Mining Supplement last month) to be observed in "any part of a mine in which inflammable gas, although not normally present, may occur in quantity sufficient to be indicative of danger."

The clause of the Act as it stands might be read to imply prohibition of electricity whenever there is the minutest risk of explosion, but it is clear from what we have quoted above, that it is only intended to apply in the most gassy parts of mines, the precautions indicated by the Committee for the installation, maintenance, and working of the plant being sufficient for ordinary working where gas is occasionally present.

It is interesting, in this connection, to review some of the evidence given before the Departmental Committee.

Mr. D. M. Mowat, general manager of the Summerlee Iron Co., Coatbridge, said that an indication of firedamp did not necessarily mean that firedamp was present in sufficient quantity so as to be dangerous. Mr. J. Gill, manager of St. John's Colliery, Normanton, Yorkshire, representing the Colliery Managers' Association, said that in a fiery colliery he would allow open-type motors in the main intake roads where lamps were lighted, but not beyond these. On the other hand, if a pit were subject to sudden outbursts of gas he should consider very seriously as to putting electrical coal-cutters in at all. Mr. A. Hall, consulting engineer, giving evidence on behalf of the Colliery Managers' Association, said that at a coal face where gas did not appear every day but was of frequent occurrence, he would use an electric coal-cutter with an enclosed motor, as he knew of no case where such a motor had fired gas. Mr. W. Maurice, manager of the Hucknall Colliery, near Nottingham, made a general statement to the effect that the use of electrical plant was quite safe, even in gaseous mines, under certain precautions. He would only not use electricity in places where it was found necessary to withdraw men at frequent intervals owing to there being a visible cap on the safety lamp. Mr. W. H. Patchell, consulting engineer, giving evidence on behalf of the Institution of Electrical Engineers, said that he could not imagine that "the Home Office would go to the length of pandering to scaremongers to the extent of excluding electricity," but, speaking for himself, there were places where he would not introduce electrical plant. Mr. R. Rutherford, representing the Durham Coalowners' Association, thought that the conditions under which the use of electricity would be dangerous were those given in General Rule 8 of the Coal Mines Regulation Act as the conditions requiring the use of safety lamps. He would use electrical plant in so-called gassy mines, but not at the face if there were frequent outbursts of gas or if a cap were frequently seen on the lamps. He could not conceive of any form of electric coal-cutter which, including its switchgear and cable, could be considered as safe in such circumstances. Mr. W. C. Mountain, managing director of Ernest Scott & Mountain, Ltd., said that he would hesitate before introducing electricity at all into places where there was likely to be very frequently an explosive mixture; there were very few such places, however. Mr. T. Y. Greener, chief engineer of the collieries of Pease & Partners, Ltd., and appointed to give evidence on behalf of the Mining Association of Great Britain, said that he did not think there were any mines in which it would not be safe to instal electrical plant on the main roads and in most parts of the mine itself, except only it might be in the working places and in the returns. Electricity should not, he thought, be used in places liable to sudden outbursts of gas, nor in places in which the air current was so charged with gas as to be approaching an explosive mixture.

Ashington Pit Fatality.—At an inquiry held a few weeks ago into the cause of the death of G. Reaveley, an engine-man in charge of an electric haulage-engine in the Bothal Yard seam of the Ashington pit, it was elicited that the man received a shock from the cover of the switchbox. It appears that a screw in the switch blade had worked loose and came in contact with the cover, and that this did not blow the fuses as the wire which connected the cover with earth was missing. A verdict of accidental death was returned.

Hosted by Google

THE PRETORIA PIT EXPLOSION

THE Home Office inquiry into the cause of the explosion at the Hulton Colliery on December 21st was concluded on March 9th, but Mr. Redmayne's report has not yet been published. It will be remembered that at the conclusion of the inquest the jury found that the explosion was due to an accidental ignition of gas and coal dust, but that the cause of ignition is unknown. As stated in ELECTRICAL ENGINEERING IN MINES, March 2nd, 1911, p. xxi, Mr. Tonge, general manager of the Hulton Collieries, expressed the opinion at the inquiry that the explosion was caused by a broken safety lamp at a fall. A lamp-room man also admitted that there had been a number of cases of damaged lamps in the mine during the six months preceding the date of the explosion. The electrical engineer to the Hulton Colliery, Mr. R. F. Bull, said that he was satisfied that the conveyer oil-switch which was suspected had sufficient oil in it to prevent sparking; and Mr. R. Nelson, H.M. Electrical Inspector of Mines, stated that there was no evidence of arcing at the contacts of the switch. He had no doubt that oil was spilt when the switch was moved out of the danger zone after the disaster, in order that he might inspect it. He had also observed no breach of the special rules now in force, and the electrical plant was well designed and installed. Dr. W. Thornton, of Armstrong College, Newcastle, gave evidence as to having examined the electrical plant, and found it in good condition. Experiments which he had made showed that an explosion in a switch-box left no signs on the inside of the box.

ELECTRICITY AND COMPRESSED AIR IN MINES

AT a meeting of the West of Scotland Branch of the Association of Mining Electrical Engineers on March 17th a Paper on the above subject by Mr. J. R. Benson, which had been read at a previous meeting, was discussed. The Paper was, on the whole, in favour of compressed air rather than electrical power, but the author wished it to be clearly understood that he was not by any means entirely against electricity in mines. He referred to comparative estimates from air and electrical coal cutters, which were in favour of the former as regards first cost of the machines and as regards the cost of the pipes and cables. He also claimed that the better efficiency of the electrical system was offset by higher cost of maintenance and supervision necessary for safety. On the other hand, he considered that for pumping he knew of nothing better for raising water from mines than the electrically driven turbine pump. For a direct drive and a uniform load it was an ideal power. He particularly emphasised the necessity for ample margin of power, especially for cutters in thin seams, and mentioned that where ten years ago a 10-h.p. motor was considered sufficient for a coal-cutter, 30- or 40-h.p. machines were now being used. He was very much against electric cables being introduced at all into fiery mines where safety lamps were in use, and in conclusion he referred to particular circumstances where compressed air had been used with success, and entered into some matter of detail as to its working. It was especially in thin seams that compressed air appeared to him to offer advantages over electric power.

The discussion was opened with the reading of a letter which was received from Mr. Spence, who thought that Mr. Benson claimed too much for compressed air when he said that it was as efficient as electricity. Compressed air to be efficient at all had got to work at full load, whereas electricity can be worked to half load with a high efficiency. He mentioned an example of the failure of compressed air as a stand-by. An electric pump was shut down for repairs, and a compressed air pump was put on in its place, but the boilers were unable to supply sufficient steam to keep up the pressure in the receivers, although they had easily supplied enough for the electric pump. When using air for drills it was usual to put down electric cables to compressors below for the air. At Rosyth Dock they had electric motors driving air compressors at points required.

Mr. THOMSON, on the other hand, spoke of estimates for both electrical and compressed air plant, where the lowest electrical estimate was £200 above any compressed air estimate. He also stated that in the case of the former more boilers were required. In a colliery he had visited, however, enough energy was lost in joints blowing in the compressed air pipe to keep another coal-cutter going.

Mr. MUIRHEAD also spoke in general terms in favour of compressed air, but admitted that electricity had not been enough in use in this country to compare it with compressed air, as regards cost of upkeep.

Mr. MCGUFFIE pointed out that radical changes had taken place in electrical cutters in the last eighteen months, while practically none had taken place in compressed air machines. Mr. Benson had tried to make out that electric power was all right for pumps and compressed air for everything else, but he himself would say that there was practically nothing in the pit which could not be driven efficiently and safely by electricity.

Mr. CASE said that where there was a power system at hand a small colliery should take a stand-by supply from it. They could use a small exhaust turbine for supplying current in place of a reciprocating set. Compressed air could not be compared to electricity for flexibility, especially where alterations had to be made. Mr. Benson had overrated the danger from shock; with up-to-date installations, armoured cables, safety boxes, and earthing there was no danger at all. In fiery mines an ideal system was to take electricity to a central station in-by, and instal squirrel-cage motors driving rotary compressors.

Mr. BENSON, in his reply, denied that he had said that compressed air was as efficient as electricity. He asserted that the cost per h.p. was practically the same, taking into consideration the cost of installing and maintaining each plant. One of the largest collieries in U.S.A. had adopted compressed air in place of a continuous-current plant. He did not himself advocate compressed air for everything in a colliery, but he did advocate it for coal-cutters, and especially for wet places. A compressed air plant, if well designed and well looked after, was as efficient as an electric plant.

ELECTRIC WINDING

AN original communication on this subject by Mr. G. Stjernberg has been accepted by the Institution of Electrical Engineers for publication in the Journal. The author points out how the steadiness of drive of the electric motor has enabled full advantage of the use of balance ropes to be taken without the dangerous swinging which the discontinuous impulses of the steam engine produce. He then proceeds to a detailed investigation of the effect of the balance rope on the design of the plant leading to results which may be summarised as follows :—

The size of a winding motor for a given arrangement of the mechanical part and a given useful load depends, in the case of a cylindrical drum with balance rope, upon the value of MS/QT^2 (where M = the equivalent mass, which, moving at rope speed, would produce the same effect as the moving parts of the gear, S = depth of shaft, Q = the static load, and T the total time allowed for the wind). This expression decides the torque, and the value of S/T decides the temperature rise. The form of the speed diagram influences the size of the motor when direct-coupled, or for a fixed ratio of gearing, not more than 5 per cent. for values of MS/QT^2 not exceeding 0·2, and not more than 10 per cent. for values of MS/QT^2 not exceeding 0·4. With geared motors, if the maximum motor-speed is given, the value of the average speed has a very great influence upon the size of the motor, which is then larger the higher the speed. The temperature rise of a winding motor under actual working conditions can be ascertained by running the motor at average speed with a load corresponding to the R.M.S. torque. The electrical efficiency can be ascertained by running the motor at average speed developing a torque equal to the R.M.S. torque. With resistance control, this test gives the sum of motor losses and the resistance losses. The motor losses during time T are equal to the motor losses taken over the diagram. The resistance losses stand in the same proportion to the mechanical output as during actual winding if no braking occurs. Resistance control can, with the limitations given in the Paper, not be considered for values of B, where $B = MS/QT^2$, larger than about 0·25. As a rule, in consideration of the peak load, the limiting value is smaller still. The most suitable values are B = 0·1 to 0·2. Ward-Leonard control with cylindrical drum can be used for values of B up to about 0·35. With Koepe discs, however, the maximum value of B is about 0·25.

In the case of a cylindrical drum without balance rope, the effect of leaving out the balance rope is to increase the R.M.S. value of the torque diagram by about one-half the torque produced by the full length of rope. For values of B smaller than 0·2 the increase is somewhat less, and somewhat more for B = 0·2. If we desire to work without braking, the value of B for which resistance control is suitable is reduced in proportion to $(1 - W/Q)$, that is, it can only come into question for values of B smaller than about 0·15. Ward-Leonard control can be used within the same limits as before, but the motors are then much larger, and the efficiency considerably less. When testing the winding motor as above the diagram efficiency has to be separately dealt with. Different winding systems and best results cannot be correctly compared without taking into consideration the value of MS/QT^2 and the value of M/Q so far as it is inherent to the system. If no balance rope is used, the value R/Q must also be considered (where R = the ratio of the R.M.S. torque during the wind to the static torque).

THE WINHEY LEAKAGE DETECTOR

IN a Paper read on March 14th before the Manchester Geological and Mining Society Mr. E. E. Baker gave a description of an instrument known as the Winhey leakage detector, the object of which is to isolate a section of a mine installation automatically directly the leakage current rises to a predetermined value. The instrument contains a relay worked by a local battery, which controls the tripping circuit of the main oil feeder switches and the detector relay, the coil of which is connected on one side to a copper earth wire run to the bottom of the pit shaft. Tappings are taken off at each pit-eye and connected to the armouring of the three-core cables which run from the pit-eye main distribution boxes, along the intake haulage roads to the motors, transformers, &c.

The author states that in testing one of these instruments on a 550-volt A.C. system the circuit could be opened automatically with an amount of leakage sufficient to cause a shock only appreciable in the nerves of the wrist and ankles. The objection might be raised that with an instrument of such sensitivity there would be inconvenience through constant interruption of supply from slight leakages, but in a twelve months' trial of the apparatus at the Rose Bridge and Douglas

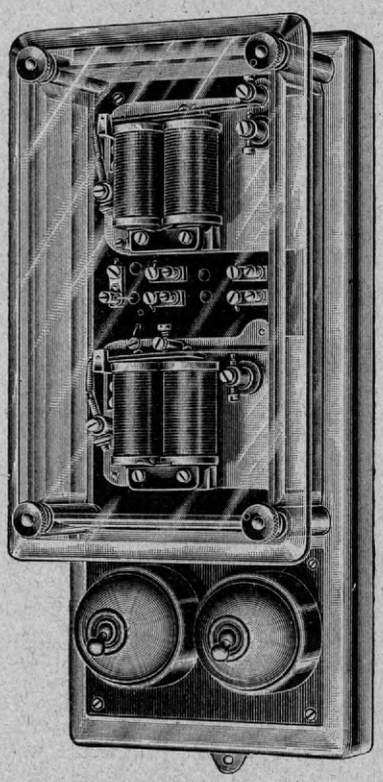

FIG. 1.—WINHEY LEAKAGE DETECTOR.

Bank Colliery the detector only came into action twice, and both cases were real breakdowns, one due to a leaky steam pipe having damaged a cable, and the other to an induction motor having gone to earth. During the experiments in connection with the design of the apparatus it was found to act with sufficient rapidity to prevent a rat, who earthed one phase of a 550-volt three-phase system, being killed.

In the installation in question the instrument was adjusted so as to allow a certain limit of leakage, and then sealed up. If a leakage beyond this limit should occur, the circuit-breakers in the shaft cables are instantly opened, and at the same time a bell is rung in the power-house, which attracts the attention of the man in charge. The circuit-breakers are of the loose-handle type, and these are then immediately put in. If the leakage has gone off, they stop in; if it is still on, they come out. His instructions are to try them once after operating, and, if the fault is still on, to send for the electrical engineer. The faulty circuit is discovered by trying one circuit at a time, and if it is considered safe to do so, the magnitude of the leakage can be seen by cutting out the detector and reading the leakage current on the leakage indicator. If it is a serious fault, the installation is still protected by the overload trips. If, however, it is small and within the allowable limit, it may be considered advisable to finish the shift with the leakage on, in which case a record is kept of its magnitude and duration.

A SAFETY SWITCH AND PLUG

THE Foster Engineering Co., Ltd. (Morden Road, Wimbledon), have introduced an automatic switch and plug for use in dangerous situations in coal mines, in powder magazines, coal bunkers of ships, or wherever there is risk of explosion. The apparatus is so arranged that it is im-

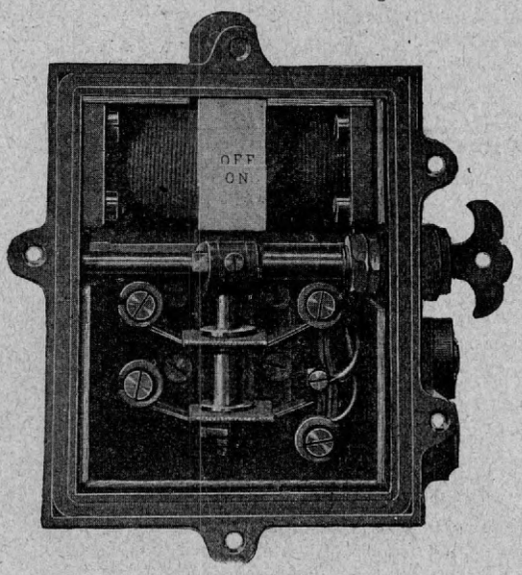

FIG. 1.—FOSTER SAFETY SWITCH.

possible to withdraw the plug from the socket unless the circuit has previously been made dead by the switch situated outside the danger zone; nor can the switch be left in the "on" position unless the plug is first inserted. Both switch and plug are water and gas tight, and of substantial construction. The principle of their operation is very simple. The switch contains an electro-magnet so arranged that it holds in the "on" position the double-pole switch when current is passing through it, but should no current be flowing

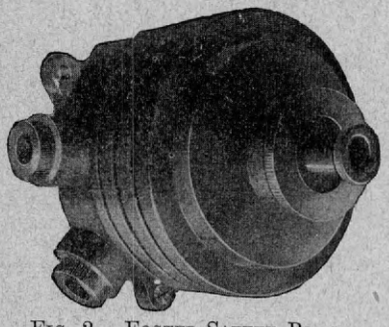

FIG. 2.—FOSTER SAFETY PLUG.

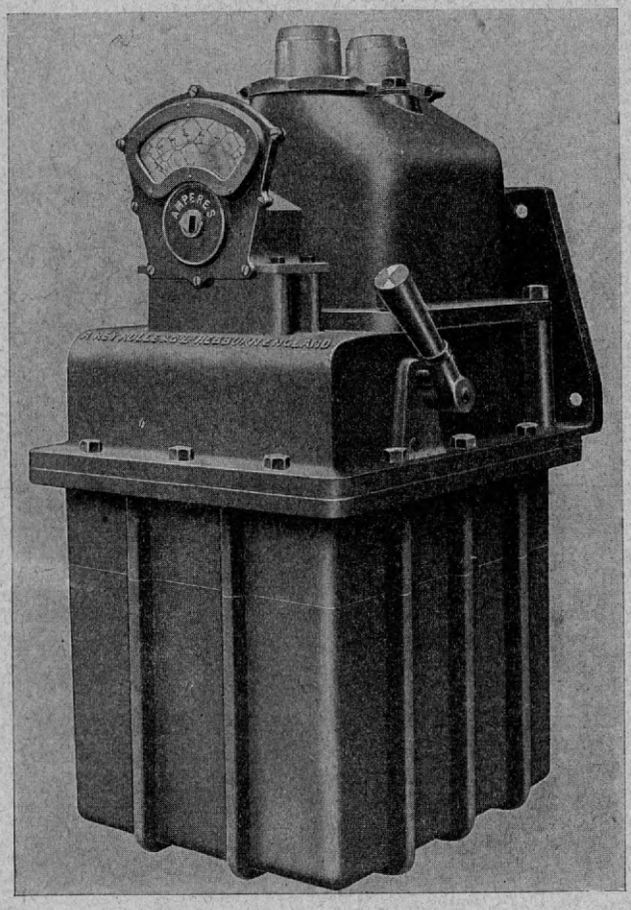
the magnet ceases to be energised, and the circuit is broken. The socket also contains an electro-magnet, so arranged that when current is passing through it a small bolt is lifted, which locks the movable plug so that it cannot be withdrawn while the current is on. The magnets in both switch and plug are in series with the rest of the circuit.

The switch, with the cover removed to show the working parts, is shown in fig. 1, and the plug which screws completely over the socket is seen in fig. 2. We understand that several of these switches and plugs are in use on battleships in the Navy.



Rescue Work.—The report of the Departmental Committee appointed by the Home Office last October to consider rescue work in mines, contains draft rules, including one to the effect that two electric hand lamps ready for immediate use and capable of giving light for at least four hours must be provided at every mine. It is also recommended that twenty such lamps should be kept in every central rescue station.

The Institution of Mining Electrical Engineers.—It has been resolved that "the Report of the Departmental Committee appointed to consider the working of the existing Special Rules for the use of Electricity in mines, may be read at the Branch Meetings with a view to instructing Members as to the meaning of the Report, the proposed New Rules, and the Memorandum, but no reports of the discussion or criticisms which may be made on the Rules shall be published in either the Official Organ or any other paper."

Hosted by Google

COLLIERY SWITCHGEAR

IN the early days of mining switchgear design the aim was to construct gas-tight apparatus of strength sufficient to withstand internal explosions, but it was soon found that it was impossible to construct switchgear either sufficiently gas-tight to avoid all possibility of an accumulation of gas inside the cases, or to ensure that they could withstand internal explosion without risk of bursting. Messrs. Reyrolle & Co., Ltd. (Hebburn-on-Tyne), have long realised these points, and their principal aim is to construct apparatus in which an

REYROLLE OIL SWITCH FOR UNDERGROUND USE.

accumulation of gas can be exploded without danger. One of the methods by which this is ensured is the provision of extra wide flanges to all the joints without tight packing, so that, as in the safety lamp, the flame is cooled before it can protrude. The firm have brought out a number of designs on these lines, and a complete three-phase oil switch equipment provided with ammeter worked by a current transformer of this kind is illustrated here. The principle has also been applied to circuit breakers, fuse boxes, motor starters, &c.

Powell Duffryn Co.'s New Pit.—Mr. J. Shaw, chairman of the Powell Duffryn Co., has stated that the new colliery at Pengam would be the first to be worked solely and entirely by electric power. The sinking and equipment of the pit, and the winding of the coal, would be done by electric power produced from waste gases and waste products.

Colliery Guide and Directory.—A new edition (1911) of "Reid's Colliery Guide" for the counties of Northumberland, Durham, and Yorkshire, has been issued by Andrew Reid & Co., of Newcastle-upon-Tyne. This comprises a list in alphabetical order of colliery owners, with the names of the collieries, agents, managers, and engineers, for the above districts. An alphabetical list of collieries is provided also with reference numbers, so that the owners, managers, &c., can be found readily from the first list. The addresses of agents, managers, and engineers are given, and also a list of Associations and Institutions in the district. Useful maps of the coalfields, on which all the collieries are clearly marked, are included. The Explosives Act of 1875 and the Orders of 1906 and 1910 are given in full, as are also the Coal Mines Regulation Acts of 1887, 1896, 1903, and 1908. The Special Rules for the use of electricity in mines are included, but not the new draft rules. Mining statistics, the Workmen's Compensation Act, 1906, and other miscellaneous information are given.

HOME OFFICE PROSECUTION

AT Hamilton, Scotland, on March 29th, Sheriff Hay Shennan gave judgment in two cases of alleged contravention of the Coal Mines Regulation Act and the Special Rules relating to the use of electricity. The case arose out of complaints made by H.M. Inspector of Mines with regard to the electrical apparatus in Millburn Pit. The defendants were Mr. R. M'Kay, resident manager of Cornsilloch Colliery, Dalserf, belonging to Messrs. Archibald Russell, Ltd., and Mr. J. Salmond, general manager to the firm. The charges against Mr. M'Kay were as follows: (1) Failure to maintain communication between two shafts (this was withdrawn as irrelevant); (2) having allowed a haulage motor to have a wood cover on both its commutator and its switch, with consequent danger of fire; (3) failure to earth the frame of the motor efficiently; (4) failure to protect the terminals and starting switch with an insulating cover or an earthed metal cover; (5) having allowed a joint in a lighting wire to be merely twisted and taped and not soldered; and (6) having had cables in a haulage road suspended on iron nails and not hung with straps. The charge against Mr. Salmond was that he had failed to have a competent person in charge of the electrical plant.

Mr. J. Masterman, H.M. Inspector of Mines, in giving evidence, said that there was no earth wire attached to the distribution box in the motor house, while the earthing of the motor frame was bad in respect that a seven-strand signal wire passed loosely through a hole in the iron frame, and was held in position by a piece of wood jammed into the hole. Mr. R. Nelson, H.M. Electrical Inspector of Mines, said that the wooden cover over the commutator was not more than three inches distant from live metal. The earthing connection provided was quite useless, and the starting switch had an exposed terminal. He had found that a joint in a lighting wire near the motor house had been made by twisting the wires together and covering the bare wire with waterproof taping. Mr. W. Walker, Chief Inspector Mines in Scotland, confirmed these statements, and mentioned that the electrician in charge, Mr. J. Young, had said that if he had erred, he had done so in ignorance. Evidence was given in defence by Mr. Young to the effect that the switch was well fenced off, and that the wood cover had been on the commutator for some years. The Sheriff convicted on charges (2), (3), and (6) relating to the commutator and switch, earthing, and the suspension of cables respectively, but rejected the other charges against Mr. M'Kay. He did not consider the offences very serious, and dismissed the defendant with an admonition.

In the case against Mr. Salmond, evidence was given by Mr. Nelson as to defective work in the pit, which he put down to the incompetency of Mr. Young; but Mr. Salmond stated that the resident manager's reports as to Young's work were good, and Mr. A. Anderson, managing director of Anderson, Boyes & Co., also spoke very highly of Mr. Young who was, he considered, quite competent to have charge of electrical plant, and particularly resourceful. The Sheriff held that the evidence showed that Mr. Salmond was entitled to regard Young as a competent person, and consequently found the defendant not guilty.

Articles of Interest to Mining Electrical Engineers published in "Electrical Engineering" during March.

March 2nd.—Monthly supplement on ELECTRICAL ENGINEERING IN MINES, opening with an article giving the main features of the report of the Home Office Committee on Electricity in Mines and the proposed new special rules. Reports are given of the adjourned discussion on Messrs. Dixon & Baxter's Paper before the Institution of Mechanical Engineers, describing the electrical coal hoists at Clydebank, and of a discussion by a branch of the Association of Mining Electrical Engineers on three-phase haulage motors. The verdict of the jury, to the effect that the cause of the Hulton Colliery explosion was not electrical, is announced. Other short articles contain a summary of Electrical Mining Patents for February, and descriptions of a transformer for mining bells and some oil-immersed motor starters.

March 9th.—Illustrated description of a new design of turbo-alternator. Results of steam consumption tests of a 6,000-kw. turbo-alternator. Discussion on high-tension transmission lines. Report of a Paper and discussion on circuit breaking.

March 16th.—Literary supplement, with reviews and list of recommended books in all branches of electrical engineering. A Paper on cable laying and jointing. Descriptions of two new types of water-tube boiler.

March 23rd.—Special article and report of a discussion on main cables. Description of a new instrument for measuri[ng] very low resistances.

March 30th.—Tests of some soldered aluminium joints.

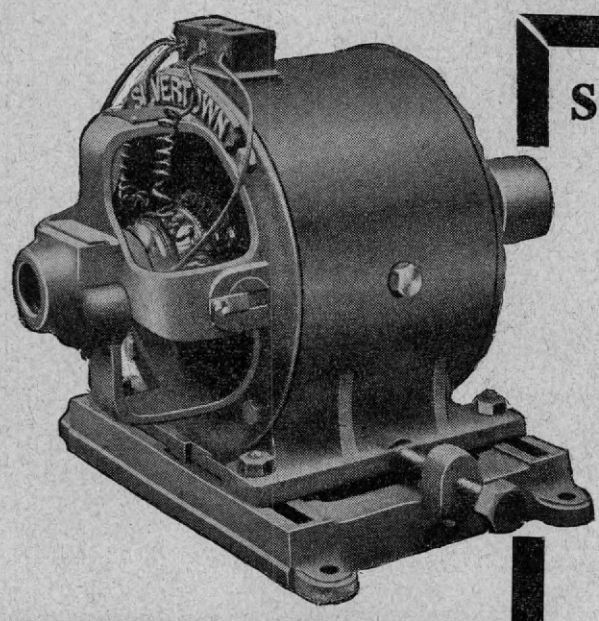
Hosted by Google

ELECTRICAL MINING PATENTS OF MARCH

Among the Patent Specifications of interest to electrical mining engineers published during the past month was one by H. F. Joel, of Forest Gate (No. 3,185 of 1910) for an electric safety lamp in which the lamp is attached to the hinged lid of the battery case. Taper pointed contact pins on the lid engage with spring clip contacts attached to the battery terminals when the lid is closed, and thus complete the lamp circuit. One of the contact pins is mounted on the end of a rod, which is threaded where it passes through the top of the lamp case, and thus makes a gas-tight joint. By rotating this rod, the circuit can be broken when the lid is closed.

Specification No. 7,388 of 1910, by E. A. Hailwood, of Morley, describes an apparatus for testing miners' lamps and for observing the percentage of a gas mixture by the height of the "cap" on the flame. The apparatus encloses the lamps, and is provided with means for regulating and indicating the composition of the gas mixture, and electric ignition arrangements.

A novel design of electric coal-cutter is described in Specification No. 10,358 of 1910, by J. C. Hirst, of Reynoldsville, U.S.A. This comprises a wheeled truck on which is mounted a motor-driven shaft provided with a bulbous head studded with a series of tangentially arranged cutters. The cutters engage with the coal successively as the shaft is swung laterally in an arc of a circle with the truck as a pivot.



Specification No. 11,792 of 1910, by C. J. Beaver and others, of Manchester, and describing a cable protected against external arcing in the event of a fault developing inside, is abstracted in the Patent Record on another page of this issue.

A safety lamp with an improved electrical igniting device is described in Specification No. 13,892 of 1910 by F. Kay, of Grimethorpe, and E. Kay, of Normanton, Yorkshire. Instead of one wire close to the wick two wires are employed and are provided with adjustable sparking buttons. When the lamp is placed on the relighting table, the sparking buttons are brought close to the wick, and as soon as ignition is effected are kept down by springs below the level of the flame, thus preventing oxidation and burning of the buttons.

Specification No. 18,135 of 1910, by L. Kovatch, of Sidney, Indiana, U.S.A., describes a movable support for an electrically driven coal punching machine enabling the machine to be tilted or swung in a lateral plane to work on the walls situated at the sides of the support.

CORRESPONDENCE

THE LIFE OF METAL FILAMENT LAMPS.

To the Editor of Electrical Engineering.

Sir,—With reference to the article on page 167 of your issue of March 30th on metal filament lamps, we note that you commence by saying "a good deal of uncertainty has existed regarding the useful life of metal filament lamps"; it would be interesting to us to hear your opinion as to what is the useful life of metal filament lamps. The Westminster Electrical Testing Laboratory, to whom you refer in the article mentioned, consider the economical life of a lamp to be at an end when the efficiency reaches 1·5 watts per candle-power, and on this basis the lamps to which you refer have no economical life whatever, the efficiency of the four lamps varying from 1·55 to 1·64 watts per candle-power. After all, the only question for the consumer is to consider which lamp will give the required light at the least cost. Now, taking current at 5d. per unit, we find that the cost of the Cryselco lamp per 1,000 candle-power hours is 7·75d. With regard to the other 14 makes, the cost varies up to 12·3d., no make showing such a low cost as the Cryselco lamp. This difference does not sound much as it stands, but if we take a dwelling-house requiring 50 lamps giving, say, 25 c.p. each, and take the lighting hours at 1,000 per year, the total cost of lighting using Cryselco lamps would amount to £40 7s. 3d. a year, whereas, using any of the other makes of lamps tested, the total cost would exceed this amount, being in the case of the lowest £43 15s. up to £64 a year for the highest. We therefore consider that we are entitled to claim that this independent test conclusively proved that the most economical and satisfactory lamp to the consumer is the Cryselco.

We are, yours faithfully,

Cryselco, Ltd., Bedford. H. T. Deacon.
March 31st, 1911. (Managing Director.)

P.S.—As some of the four lamps of some makes failed in less than 1,000 hours (not Cryselco), the proportionate cost of replacing is included in the above figures, i.e., if a lamp failed at 700 hours, three-tenths of the cost of a new lamp is charged.

SOLDERED ALUMINIUM JOINTS.

To the Editor of Electrical Engineering.

Sir,—In last week's issue of Electrical Engineering I notice there is a paragraph on soldering aluminium joints, and reference to a company called the Vacuum Engineering Co., who have introduced what they claim to be something quite new.

It has been possible for some time now to solder aluminium in a highly satisfactory manner by using the patent solder made by Standard Alloys, Ltd., of Carpenters Road, Stratford, E. This solder has been used by several of the leading cable manufacturers in this country, and wherever tried, so far as one can ascertain, has given entire satisfaction. It is very simple to use, and a workman after once being shown can easily apply it. It has been found after exhaustive tests that the soldered portion of the joint is stronger than any other part, and that it is not attacked by acids, nor does disintegration take place after it has been in use, as is the case with all other forms of solder when used with aluminium.

It appears to me that if this solder were only better known it should command a ready sale, so that if any of your readers are in difficulty with regard to soldering aluminium, or the jointing of aluminium cables, let them communicate with the Standard Alloys, Ltd., who, I think, will soon remove their troubles.

Yours faithfully,

7 Victoria Street, S.W. Horace Boot.
April 3rd, 1911.

ELECTRICITY METERS.

To the Editor of Electrical Engineering.

Sir,—Your correspondents, Messrs. Simplex Conduits, Ltd., claim that commutator meters are not so bad as painted by the authors of the recent important I.E.E. Paper. No doubt the better class commutator meters can show better results than those shown by the curves in the paper. At least, this is possible when the meters are new and clean. However, the curves are remarkably similar to those which we have recently published in the electrical press. Our curves are the results of a test made by the engineers of a Continental capital, who have in use thousands of commutator meters and thousands of Ferranti mercury meters. The test is one of the most practical which we have yet seen, and was applied to meters which had been in service for a period of two years without any examination or repair, and ten meters of each class were tested *in situ*. The curves of four different makes of commutator ampere hour meters showed errors as follows, viz. :—

Nos.	1.	2.	3.	4.
		Per cent.	Per cent.	Per cent.
Half load	OK	− 3	− 3	− 3
Fifth ,, ...	− 4·8	− 5·9	− 6·3	− 6·5
Tenth ,, ...	− 9·8	− 33·1/3	− 16	− 19

The curve of the Ferranti mercury motor meter shows the meters within 1 per cent. from full to 1/20th load.

Accuracy on low loads is really far more important than first cost of the meters, in view of the extensive adoption of low-current lamps.

Your correspondents' letter is in curious contrast with their advertisement in the same issue, since they announce in an advertisement, "Ready Shortly. New Mercury Ampere Hour Motor Meter for Continuous Current."

Yours faithfully,

Hollinwood, Ferranti, Limited.
April 3rd, 1911. R. H. Schofield.

To the Editor of Electrical Engineering.

Sir,—Messrs. Ratcliff & Moore's Paper on integrating meters will be greatly appreciated by many who are unable to make more than a superficial study of the instruments upon the accuracy of which so much depends.

Meters of large size are usually selected with care and kept under fairly close observation, but many of the instruments being sold at the present time for registering energy used for lighting, are not sufficiently well made in detail, and when placed on consumers' premises do not keep up a sufficiently high average of accuracy; the chief cause of this is possibly to be found in the quite unnecessarily large number of meter makers, and the ruinous competition at present existing between them with regard to the smaller-sized meters.

In some instances the prices quoted appear to be tentative only and subject to reduction by as much as 15 per cent., not so much in regard to the size of the purchase in view, but rather depending upon the keenness of the buyer and the immediate state of the seller's order book—these conditions are not good for the meters or those whose revenue depends to a great extent upon their accuracy.

The difference between test-room results and average accuracy over long periods when subjected to dust, moisture, temperature changes, and vibration, depends almost as much upon mechanical details of construction as upon correct design of the essential parts—these details, the fitness of which is only proved by time, are apt to suffer considerably in the attempt to cheapen production.

The most serious trouble with meters used for lighting circuits arises, not from inaccuracy, but from failure, after a short time, to register at small loads, a defect which arises almost entirely from the works of the meter being insufficiently protected against external influences. On alternating systems where the use of low voltages reduces the minimum load which can be put upon the meter, this fault may cause serious trouble, failure to register under 40 watts permitting 2–16 c.p. lamps to be used free; on small premises, where light may be used in only one room for many hours during the year, this leakage may represent a large percentage of the annual bill—an amount, in fact, which would have paid the difference in cost of a superior type of meter.

April 3rd, 1911. J. W. B.

At the close of the discussion on Messrs. Ratcliff and Moore's Paper on meters before the Institution of Electrical Engineers on March 23rd, several gentlemen who had hoped to speak were prevented from doing so by the lateness of the hour, and were invited to send in written contributions.

Mr. C. C. Paterson (National Physical Laboratory) has sent us a copy of his communication, in which he endorses the author's view that indicating wattmeters used for testing A.C. meters often read low on lagging currents owing to metal parts near the windings. He says that this is particularly the case with heavy currents. It had been suggested that the standard wattmeter might be tested against an induction meter. This was not so absurd as it sounded, for he knew of more than one type of precision wattmeter whose change of accuracy between unity and 0·5 power factor exceeded that usually met with in induction watt-hour meters. It was important on account of interaction of the circuits to test three-phase meters on actual three-phase circuits, and not on single-phase circuits only. It was also essential to know which element was to be connected to the leading and which to the lagging phase of the system. At the National Physical Laboratory they certified the errors of the meter for both methods of connection, but the whole difficulty would be overcome if meter makers would distinctly mark which element was to be connected to each phase. If these precautions were taken, he considered that the three-phase watt-hour meter was as reliable and accurate as any other form of integrating meter.

We have also received a communication on the subject from Mr. E. B. Schattner, particularly directed to contraverting statements in the discussion regarding the inaccuracy at low loads after a period of service of commutator ampere-hour meters, and the liability of the insulation of the commutator segments to break down. The commutator meter was introduced, he says,

Hosted by Google

originally on the Continent to supply the demand for a simple ampere-hour meter not so liable to derangement as most of the then existing watt-hour meters. The mercury meter was at that time not known on the Continent, and was also very imperfect as manufactured in England.

Generally speaking, the climate on the Continent is of a dry nature, and porous insulating materials, such as fibre and press-pahn, were giving satisfactory results. Also the majority of important supply systems on the Continent were at 100 volts. It was therefore essential that a meter should not have a higher drop in volts than 0·6 to 1 volt. These instruments were then imported into this country, and on the strength of favourable Continental experience, it was not found difficult to effect immediate sales. We know now, however, that the insulating materials above mentioned are of no use in this country. We also know, that whilst a commutator that will not appreciably change its surface resistance in a dry atmosphere, will do so to a considerable extent in a moist and sulphurous atmosphere, and so it happened that these Continental meters developed serious faults.

The above considerations were taken into account when the Company, with which Mr. Schattner is identified, designed the E.A.C. high torque meter about three years ago, a meter now largely used. By the exclusive employment of pure mica for insulation purposes (except under the commutator) insulation troubles were avoided, although a large number of seaside towns have them in continuous use. The commutator segments are built up on a solid ebonite sleeve, and no single case of break-down has been heard of. The prevailing voltages in this country lie between 200–250 volts; a higher and more suitable drop in volts could be employed, diminishing the influence of contact resistance.

The Company have been able to construct an armature having as high a resistance as 7·5 ohms, without sacrificing torque, and the maximum error which can occur in the E.A.C. meter owing to change of resistance on the commutator surface is not likely to exceed 2½ per cent., that under the same conditions a very much larger error will occur in meters having a correspondingly smaller drop in volts.

GAS AND ELECTRIC TRAIN LIGHTING

MAJOR PRINGLE'S Board of Trade Report on the collision, last December, near Hawes Junction on the Midland Railway, has now been published, and contains some interesting remarks on the relative safety of gas and electric train lighting. It cannot be denied, he says, that compressed oil gas stored in the cylinders under the first two coaches was the origin of the fire. Nor can it be denied that there is greater liability to fire, in a railway accident of this description, when gas is used as the illuminant, than with electric light. For it is a simple matter to prevent danger from short circuiting of electric wires by the proper provision and arrangement of fuses. He points out that the elimination of gas as a source of lighting would not preclude all danger from fire, as the risk from the contents of the fire-box of the locomotive and the cooking stoves in the restaurant cars would still remain. In fairness to gas, he remarks that this is the first fatal train fire in this country directly attributed to gas train lighting (although, as is well known, several such accidents have occurred in America and on the Continent), and says that it is only reasonable therefore first to consider, before entirely condemning it, whether it is possible to safeguard the use of gas as an illuminant, by the adoption of any improvement in appliances, which may minimise the risk of fire. Several suggestions for lessening the risk with gas are discussed, but finally Major Pringle writes :—

But even with every such possible precaution, it will remain true that electric lighting will still be the safer method. On grounds of safety, therefore, I still hold that electricity is the more desirable means of illumination for passenger trains, and as such should be adopted wherever possible. In the case of long distance and express trains, it is more particularly to be recommended. In the meantime, for of necessity a long period must elapse, during which gas will still be very largely used as an illuminant, a good deal can be done in the directions above suggested to reduce the liability to fire from its use.

THE LODGE WIRELESS PATENT

ON Tuesday the petition of the Lodge-Muirhead Wireless and General Telegraphy Syndicate, Ltd., for an extension of the term of Patent No. 11,575 of 1897, granted to Sir Oliver Lodge, came before Mr. Justice Parker in the Chancery Division of the High Court. The ground upon which an extension of term may be granted is that the patentee has been inadequately remunerated for his invention, and the period of extension may be seven years, or, in exceptional cases, fourteen years. No objections have been lodged to the extension except by the Crown, who allege that the invention was not of sufficient merit to deserve extension, and that no attempt was made during the fourteen years of ordinary life to protect the rights of the patent.

Mr. A. J. Walter, K.C., and Mr. J. Hunter Gray are appearing for the Lodge-Muirhead Syndicate, and the Solicitor-General (Sir John Simon, K.C.) and Mr. Sargant for the Crown. Expert evidence is being given by Sir Oliver Lodge and Dr. S. P. Thompson for the petitioners.

In opening the case, Mr. Walter sketched in detail the history of wireless telegraphy previous to the date of the patent in question, and then read the specification, which describes a syntonised system of wireless telegraphy, in which the radiator sends out a prolonged series of waves of a definite frequency, and the receiving apparatus resonates in response, very feeble impulse being gradually strengthened until they produce an effect on the coherer. Various arrangements of transmitting and receiving apparatus are described, the essential features being the introduction of an inductance coil in the aerial circuit to prolong the oscillations, and to make it a radiator of definite wave frequency, the use of variable inductances for tuning, and the closing of the oscillatory receiving circuit, so that oscillations can be gradually built up from small beginnings, the coherer being in a derived or shunt circuit. The specification also describes the use of a transformer in the receiving circuit, the coherer being placed in the secondary.

The first of the eleven claims covers the insertion of an inductance coil in the sending aerial; the second covers the same thing for the receiving circuit; the third covers the bridging of the spark-gap in the aerial to make it a receiving aerial; the fourth and fifth, variable inductances; the sixth, means of exciting the oscillating circuit; and the ninth, the use of a transformer in the receiving circuit. Mr. Walter agreed, on the suggestion of the Crown, that claims 7, 8, 10, and 11 were of no importance.

Mr. Walter asserted that, previous to this patent, tuning was absolutely impossible with any system of wireless telegraphy, as all then employed a coherer directly in the receiving aerial. As the coherer was necessarily a break in the continuity of the electrical circuit, it was impossible that minute oscillations could be induced in the aerial by feeble waves and built up by resonance. By using a closed aerial circuit with the coherer either shunted off the inductance coil or arranged in the secondary of a transformer, as described by Lodge, this building-up effect was made possible, and tuning could be effected.

Mr. Justice Parker here mentioned that if this were so, all the systems of wireless telegraphy utilising the principle of resonance infringed the Lodge patent, and that if he granted an extension, the Lodge-Muirhead Syndicate could come upon them for heavy royalties, and thus cripple their business. He was obliged to consider the effect of his decision upon the general public. Mr. Walter, however, urged that his lordship had only to consider what had taken place during the 14 years' life of the patent, and should not take into account what might happen as the result of a grant of extension. The syndicate would be willing to grant licences on reasonable terms, which might, if desired, be settled by the Board of Trade.

Turning to the alleged neglect to protect the rights of the patent, Mr. Walter explained that little progress was made in the working of the patent during the first few years on account of the difficulty of securing a reliable coherer. In 1901 a private company was formed with a capital of £50,000, most of which was found by Messrs. Muirhead. Thousands of pounds were expended on experiments, and experimental stations were constructed. In 1902 the well-known Lodge-Muirhead coherer was invented, and this proved commercially successful. It was so perfect that messages could be recorded from it in ink by means of a siphon recorder as used in cable telegraphy. Continued experiments were then made in conjunction with the War Office and Admiralty, and in 1903 the India Office purchased an installation for the Andaman Islands. The receipts of royalties, &c., from the India Office, U.S. Army, Trinidad, and Zanzibar Governments, &c., amounted, during the 14 years of the patent, to nearly £6,000 less than the amount expended on experiments, &c., namely, £33,167. This latter sum did not include anything for the personal time of either Sir Oliver Lodge or Dr. Muirhead. In 1904 they considered that the Admiralty, who were using a system of their own, were infringing the patent, and approached them in the matter, but the Admiralty refused to put up anyone whom they could sue. Recently, however, they had come to terms, the Admiralty agreeing to pay a certain sum. They had been refused a licence by the Post Office for a coast station in 1905, and had not been able, therefore, to engage in the very remunerative business of communicating with ships at sea. Further, they had entered into an action against the Marconi Co., but this was settled between the parties, the Marconi Co. refusing to raise the question of their 1896 patent, which it was the wish of the Lodge-Muirhead Syndicate to do.

Sir Oliver Lodge was then called in evidence, and stated that he did not turn his attention seriously to the application of Hertzian waves to telegraphy until 1896, after Mr. Marconi's early work had been brought before the public. He then explained clearly the reason and importance of the different features of the patent in question.

The case is still proceeding.

ELECTRIC TRACTION ON THE SWEDISH STATE RAILWAYS

The 80-mile Kiruna—Riksgransen Section.

WORK has already been commenced on the conversion to electric traction of an 80-mile section of a full-gauge line of the Swedish State Railways in the extreme north of Sweden, and the equipment is to be complete in the year 1914. The section in question is between Kiruna, where there are extensive deposits of iron ore, and Riksgränsen, on the border between Sweden and Norway. The continuation of the line in Norwegian territory connects Riksgränsen with Narvik, a seaport from which the ore is shipped to the smelting centres. Although the traffic consists mainly of ore trucks, there is a certain amount of passenger and general goods traffic, and special locomotives for passenger trains will be provided. A feature of the line is that it is wholly within the Arctic circle and heavy falls of snow have to be dealt with in the winter months.

There is no coal in the north of Sweden, and only a very small amount in the south, and consequently all the coal for the railways has to be imported, and is high in price. There is an abundant supply of water power, however, and should the present electrification prove successful, the whole system of railways will no doubt eventually be converted to electric working. It will be remembered that as a result of the experiments carried out near Stockholm between 1905 and 1907, the State authorities decided to employ the single-phase system. In the present case, a trolley-line pressure of 15,000 volts and a frequency of 15 cycles per sec. will be employed, as is favoured in Germany and Switzerland. In May of this year the Swedish Parliament granted for the present work a sum of approximately £1,200,000 (of which £270,000 will be forthcoming this year), and the contract for the whole of the electrical work was given to the Allmänna Svenska Elektriska Aktiebolaget, of Westeras, Sweden, and the Siemens-Schuckertwerke-Ges., of Berlin, who have guaranteed that the running costs shall not exceed certain limits.

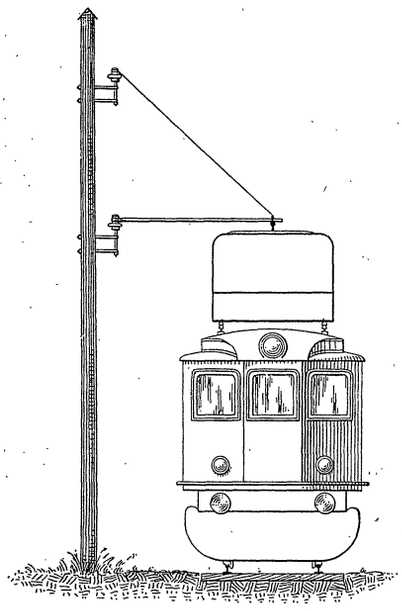

Fig. 1.—Trolley-wire Suspension.

The line is single track, and the traffic is increasing rapidly, but the introduction of electric traction will render unnecessary any immediate duplication of the track. At present the trains consist of not more than 28 loaded trucks, weighing 35 tons each, and a general goods wagon, hauled by a locomotive of the heaviest type employed in Sweden. With electric traction, each train will consist of 40 loaded trucks, a goods wagon, and two electric locomotives, one in front and one behind, and will weigh 2,050 tons. Eight such trains will run daily in each direction. A maximum speed of from 30 to 38 miles per hour will be attained, whereas with the present steam trains the maximum speed reached is only 25 miles per hour. The speed on the heaviest gradient, viz., 1 per cent., will be increased from 7·5 to 19 miles per hour. Apart from the increase in the capacity of the line, electric working will effect a yearly saving to the Government of over £23,600 in the running costs, as compared with steam traction, assuming the guaranteed costs of the contracting firms, and a yearly transport of 3,850,000 tons of ore, which is the figure estimated for the year 1918, on the basis of the increase during the last few years.

Power will be supplied from a water-power station to be erected at Porjus, some 74 miles south of Kiruna, on the river Luleälf. The falls there will provide far more power than will be required for the railways in the vicinity, but it is expected that a large amount of energy will be utilised for industrial purposes, including electric smelting of iron and zinc. The lake of Porjus will be dammed up just above the falls, which will provide an effective head varying between 158 and 188 ft., according to the season. The power station itself will be constructed underground in the solid rock. Five turbine units of 12,500 h.p. each will be installed, with three single-phase alternators generating at 5,000 volts, 15 cycles, and two three-phase alternators generating at 25 cycles. The latter will be for the industrial power supply. Access to the station will be gained by two lifts. The switchgear and transformers will be housed in a separate building above ground. For the purpose of constructing this station and to assist in the industrial development of the neighbourhod, a special railway is being built connecting Porjus to Gellivare, a town on the main line, 60 miles south of Kiruna. From the power station current will be transmitted over a steel pole line at a pressure of 80,000 volts to four transformer sub-stations at various points along the line.

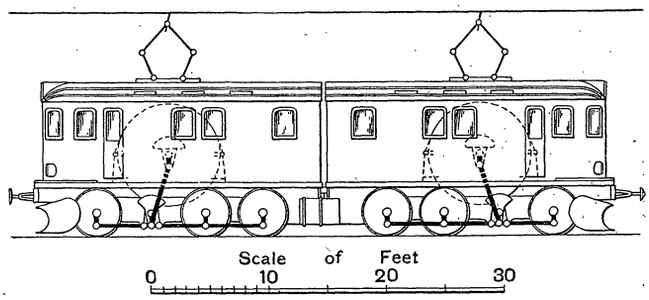

Fig. 2.—Goods Train Locomotive.

The trolley line, which will supply current to the locomotives at 15,000 volts, will have the very simple suspension illustrated in Fig. 1. The trolley wire itself is attached directly without the interposition of insulators, at intervals of 33 yards, to an iron tube supported at one end on an insulator fixed to a wooden pole and held at the other by a steel wire attached to another insulator at the top of the pole. This simple construction was tested during the trials near Stockholm in 1906, and proved satisfactory. The attachment of the wire to the tube is such that a certain amount of longitudinal movement of the wire is possible under the influence of changes in temperature, the sag being taken up automatically by suspended weights at the end of each section. Vertical movement under the upward pressure of the collector bow is also possible at the points of suspension.

A diagram illustrating the general design for the goods locomotives is given in Fig. 2. It consists of two self-contained units, each with three coupled axles driven through a coupling rod and an intermediate shaft by a large commutator motor of the compensated series type. Each half of the locomotive has its own transformer, switchgear, and collector. Fig. 3 shows the design for the passenger train locomotives. This has a single motor driving two coupled axles through a coupling rod and an intermediate shaft, while a four-wheel bogie is provided at each end to give smoother running. The total weight of this type will be about 70 tons. A speed of over 60 miles per hour will be attained by the passenger trains.

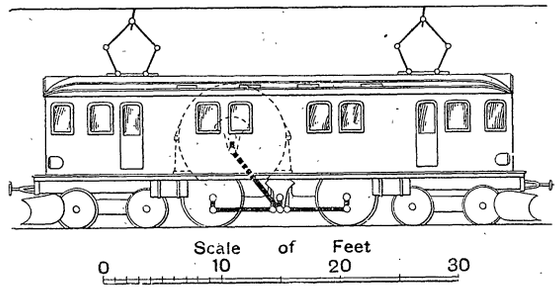

Fig. 3.—Passenger Train Locomotive.

Most of the above information is taken from an article by J. Oefverholm, an official of the Swedish State Railways, in a recent issue of *Elektrische Kraftbetriebe u. Bahnen.*

The Old Ferrantians Dinner.—The date of this dinner, which is to be held at the Trocadero Restaurant, has been fixed for Saturday, April 29th. Tickets can be obtained from the Hon. Sec., Mr. W. E. Warrilow, "Selwyn," Mildred Avenue, Watford.

Hosted by Google

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

ONE of the most difficult problems which the electro-metallurgist has been called upon to face is that of the production of zinc from its ores in the electric furnace. The electrometallurgy of zinc is one of the least satisfactory of metallurgical operations. This is readily understood when it is mentioned that the reduction of zinc oxide by means of carbon to the metal requires a temperature of at least 100° C. above the boiling point of the metal. Furthermore, the metallic vapour when formed is extremely readily oxidised, and when a portion is oxidised it is not easy to get the metal to condense as a liquid, the tendency being for a blue powder containing oxide to be produced. In the circumstances it is therefore not surprising that many attempts have recently been made to produce zinc from its ores by electro-thermic methods. Gustave Gin recommends his induction furnace for the production of pure zinc directly from its ores. Iron and carbon are employed as reducing agents, and a yield of 65 per cent. is obtained. The iron required for reducing purposes is first melted in the furnace, then the calculated mixture of ore, coke, and flux added, after which the furnace is sealed up, except for the flues leading to the condensing chamber. The condensing chambers are kept at a temperature of about 500°, which aids in obtaining the metal in the form of a liquid.

According to Ingalls, a zinc process could only pay if the cost per h.p. did not exceed 50s. per annum. Côte and Pierron take advantage of the greater affinity of sulphur for iron than for zinc, and reduce zinc blende with iron. This also causes reduction of the lead sulphide in the blende, which takes place at a lower temperature than the reduction of the zinc sulphide. The lead is tapped off and then the temperature raised when the zinc blende is reduced. The chief point, however, is in the method employed for the condensation of the zinc vapour. The condensing chamber consists of a firebrick shaft filled with broken carbon, and is provided at the bottom with a door through which the molten zinc is tapped. The carbon in the shaft is kept at a temperature above the melting point of zinc, and the partially oxidised vapour is reduced, so also is any carbon monoxide which would otherwise react on the zinc vapour.

Woolsey McA. Johnson has also devised a furnace in which smaller quantities of carbon than are employed in the ordinary methods for reduction can be employed. Only so much carbon as is necessary for reduction is employed, whereas in ordinary practice a considerable excess is required; consequently an easily fusible slag which may be tapped off is obtained. The lead, copper, and iron in the ore are reduced and collect below the slag, and are tapped off. Fresh portions of charge are added either continuously or at intervals, thus a continuous operation is secured. The mineral components of the mixture, and which form the slag, are proportioned so as to give a slag melting at 1,100° to 1,175° C., the slag being superheated to 1,250° to 1,300° C., is consequently readily tapped.

The gases which are produced are oxidising in character, and would thus prevent efficient condensation, therefore they are passed along with the zinc vapours through a shaft packed with carbon which is artificially heated. This is done by passing an electric current through the column of coke, through which the vapours pass, which heats it to a temperature of 1,020° C. to 1,150° C., thus ensuring perfect reduction.

Another method is that of Hiram W. Hixon. In this process a shaft furnace with a carbon bottom plate which acts as one electrode is employed, the other carbon electrode is placed near the top of the shaft. The charge acts as a resister, and consists of a mixture of zinc ore and carbon, which is packed in between the electrodes and extends above the top electrode. In order that the zinc vapours may not get out into the air, the shaft is provided with a double hopper; an upper door may be opened for feeding in a new charge, a lower door being kept shut. The upper door is then closed, and when the charge has been pre-heated to a sufficiently high temperature, the lower door is opened and the charge allowed to enter the furnace. The zinc vapours are drawn off near the bottom of the shaft, and pass into the condenser. At the top of the tap hole a number of arcs are provided, to prevent the tap hole being choked with "blue powder" (a mixture of zinc metal and zinc oxide in the form of a powder). An exhaust pipe is also provided at the top of the furnace to pump out the carbon dioxide and moisture.

It is obvious from these notes that the question of the treatment of zinc ores electrically is receiving serious attention, and probably the time is not far distant when the 50-lb. zinc retorts will be relegated to the scrap heap, and zinc reduction, like other metallurgical operations, will be worked in large units.

The second and third of the series of Cantor lectures on electric heating, by Prof. J. A. Fleming, at the Royal Society of Arts, were delivered on March 13th and 20th, and were devoted to electric furnaces. (The first lecture on March 6th dealt with the laws of heating and pyrometry only.) After describing the different arc and combined resistance and arc furnaces for the production of steel from pig and scrap iron, Prof. Fleming discussed the electric smelting of ore, pointing out that of the coke used in an ordinary blast furnace, only a small quantity was used for heating, and that for electric smelting to be as economical in this country the power would have to be available at a cost of not more than 1-20d. per unit. He then described the Keller smelting furnace, which had been used with success and economy in Sweden when fuel was dear and electric energy cheap. A drawback to arc furnaces for steel production was that carbon was taken up by the charge from the electrodes. The induction furnace, first constructed by Mr. S. Z. de Ferranti, got over this trouble. The Röchling-Rodenhauser furnace combined the induction with the resistance furnace in order to raise the power factor. Among the other furnaces described by the lecturer were the Electro-Bessemer furnace, a combination of an arc furnace and a Bessemer converter, and the Moissan arc furnace for laboratory purposes. Finally, Prof. Fleming showed that the most economical section for the electrodes of arc furnaces was that for which the heat lost by radiation from the outer end was equal to half the resistance loss in the electrode. A larger section would cause more heat to be conducted away, a smaller section more heat to be lost in resistance.

Prof. Fleming then dealt with the important manufactures in which the electric furnace is employed. Carborundum, a carbide of silicon, was, he said, produced by fusing a mixture of sand and coke in the Acheson resistance furnace, and large quantities were manufactured at Niagara. Artificial graphite for lubricants, "lead" pencils, &c., was also produced in a resistance furnace. Aluminium was manufactured from an oxide of the metal, alumina, by first melting a mixture of cryolite and fluor-spar in which alumina could be dissolved. At the British Aluminium Co.'s works at Kinlochleven, a large number of melting pots were employed, each absorbing about 60 h.p. About half of this was required to keep the mixture molten and half to electrolyse the dissolved alumina. The dissolving mixture was not affected. Alumina was added continuously, and the metallic aluminium deposited on the cathode sank to the bottom of the pot and was drawn off at intervals. By heating a mixture of lime and coke in a resistance furnace, calcium carbide was produced. It was thought at one time that there would be a large demand for this substance for illuminating purposes, but this was not realised. The large works which had been erected, however, were utilised to manufacture artificial fertilisers, which were produced by combining nitrogen with the calcium carbide, thus forming cyanamide. Another product of the electric furnace was quartz glass, which was proving invaluable in chemical and other work. Turning to the applications of the electric furnace in iron and steel manufacture, Prof. Fleming pointed out that by obviating the necessity for blowing air through the steel as in the Bessemer converter, the danger of occluded gases was practically eliminated. The presence of sulphur, phosphorus, and troublesome oxides which originated from the coke used for heating was also practically prevented, and the addition of exactly the correct quantities of such metals as vanadium, nickel, chromium, or tungsten to produce special steels was facilitated.

Testing Transformer Iron.—An original communication on the above subject, by Mr. L. W. Wild, has been published in the last number of the *Journal* of the Institution of Electrical Engineers. The Paper contains an investigation of the "Washington" system employed by the American National Bureau of Standards, in which a number of strips, each 10 in. by 2 in., are built up into a square, with interleaved joints, with special bent corner pieces. Coils are slipped over two opposite sides of the square, and an alternating-current wattmeter is used in conjunction with an electrostatic wattmeter to determine the losses in the iron. A large number of tests with certain alloys are given in the Paper, and the magnitude of various causes of error in investigation. The final conclusion is that the method is not very suitable for the particular alloys tested, and that if it should be decided that the interleaved method with rounded corners is the most accurate, it is hardly necessary to trouble about cutting the corners round. If the amount of waste material at the corners is deducted from the gross weight, the results obtained will not differ by more than 1 per cent. from the results that would have been obtained had the corners been rounded. It appears, however, to the author that the interleaved method is still the best method of testing transformer iron available. It is generally agreed that if accurate results are to be obtained the strips must be annealed after being cut, and this can only properly be done by the manufacturer. There is no special virtue in using wide strips. Strips, say, 10×1 would be in many ways preferable to strips 2 in. wide. Corner effects would be reduced by one-half, and, with the same area of iron, the length per turn in the magnetising coil would be reduced, thus reducing the CR drop and improving the form factor.

ELECTRICITY IN AGRICULTURE

At a meeting of the Farmers' Club, in London, on Monday, Mr. J. H. Priestley gave a lecture on "Electricity as a Factor in Crop Production." Mr. E. Packard, Chairman of Club, presided. The bulk of the lecture was a recapitulation of the experiments which have been carried out by Mr. J. E. Newman, in conjunction with Sir Oliver Lodge and Mr. Lionel Lodge, and with the co-operation of Mr. Raymond Bomford, of Evesham, supplemented by experiments by Mr. Priestley himself. In these, a network of wires is erected over the land under cultivation, and is kept charged with positive electricity at high potential. We gave a review of this work in Electrical Engineering for July 21st, 1910, p. 475, the actual figures and facts given there being repeated by Mr. Priestley on Monday.

Mr. Priestley also dealt with the application of electric light in greenhouses for stimulating plant growth, and mentioned experiments with the Cooper-Hewitt mercury vapour lamp, and also with a quartz mercury vapour lamp. The result of the experiments so far seem to indicate that plants exposed to the lamps have grown more rapidly, and, if anything, were more sturdy than plants not exposed in this manner; there were no signs of the lanky, unnatural extension of the plant usually associated with forcing. With the Cooper-Hewitt lamp the method of treatment has been, subsequent to the usual exposure to daylight, to put the plants under the rays for about two hours, at a distance of about four feet from the lamp. At this distance it has been found that the dangerous effects of the ultra-violet rays coming from the lamp are lost. Similar effects were found in the experiment with the quartz mercury vapour lamp, namely, that at close range growth was retarded or entirely inhibited, but at greater distances, or behind a glass screen, a marked acceleration and invigoration was noticeable, if the light was used as complementary to ordinary daylight. One extraordinary result obtained was that in the case of mustard seedlings exposed to the lamp at close range, the plants are of an absolutely glabrous type, instead of, as usual, very hairy. The plants close to the lamp do not possess, either on stem or leaves, a single hair. Further away from the lamp, hairs develop only upon the side away from the light, whilst shaded behind glass the plants are approximately as hairy as usual. These experiments are being continued.

Mr. Robertson Scott, who opened the discussion, drew attention to the meagre grant of £50 made by the Board of Agriculture for the purpose of these experiments. He further suggested that the Agricultural Colleges of Wye and Rothampstead should be assisted in carrying on experiments of this character owing to the difficulty of the ordinary farmer setting aside land for the purpose. He asked if it were not possible to experiment with hops and sugar beet.

Mr. J. E. Newman called attention to the necessity for thoroughly testing the overhead wires, in order to see that a proper discharge was taking place. It had happened that, although the wires themselves were fully charged, yet the crops were receiving no benefit owing to an excessive discharge taking place down the wet poles, and he was inclined to think that this had happened in certain cases where no benefit had been derived from the electrical method. He had had five different crops of wheat in three different fields, and in each year there had been an increase in the yield; so distinct was the improvement in the electrified crop, that a line of demarcation in the field could be plainly seen. Probably it would be eventually found that the best results would be obtained by using very high pressures for short periods during the day, as distinct from the present method, which, for economical reasons, was to use a small amount of current all day.

Dr. Voelcker expressed his doubts as to electricity being applicable to agriculture in the broad sense.

Mr. Charles Bathurst, M.P., suggested that a resolution should be passed by the Club, urging further action on the part of the Board of Agriculture. He asked to what extent electrical methods could be used for replacing sunlight, and what was the effect upon the quality as well as the quantity of the crop. Further, did the electrical treatment have the effect of stimulating noxious bacteria in the soil? At Rothampstead, during the past few years, some interesting experiments had been carried out in sterilising soils, and perhaps the electrical method could be worked in conjunction.

Mr. Alfred Amos said that hop-growers would be ready to adopt the electrical method if any benefit could be shown.

The Chairman pointed out that the Board of Agriculture was quite willing to make grants if they had the money, but at present they had not the funds.

Mr. Priestley, in replying to the discussion, said that in Germany experiments were being tried by treating the plants with an electrified spray in order to get over the difficulty that electrified crops produced less in dry weather. The difficulty in applying the method to hops was that there was a danger of there being electrified poles and not electrified crops. If the hop poles could be abolished, something could be done. He had tried experiments, with satisfactory results, upon sugar beet, but nothing could be done here unless sugar beet was introduced as an industry. The cost of installing the plant was from £10 to £5 an acre, according to the scale. He asked the Club not to blame the Board of Agriculture, as he had not asked for an additional grant to the £50 allotted him for experiments in this connection. The electrical method he did not think could replace sunlight entirely, and as to the effect upon the quality, he could only say that millers paid more for wheat produced under electrification, and he concluded that the quality must have been better. As to bacteria, he could not answer. So far he had experimented with the desirable bacteria, and had found that electrical treatment stimulated them. He hoped to get on to the noxious bacteria later.

At the close of the discussion, the Chairman was asked to write to the Board of Agriculture suggesting that the general opinion of the members was in favour of a larger grant being made.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

FACTORY ACCESSORIES, &c.—A new list from the British Central Electrical Co. (84 Hatton Garden, E.C.), which they describe as their Home Office list, contains particulars of a range of accessories that they are supplying to meet the regulations and recommendations of the Home Office under the Factory Acts. The cover bears the inscription "Guard against Accidents by using our 'Handshield' Accessories," and the apparatus dealt with includes a number of patterns of shielded wall plugs, distribution boards with shielded fuses, insulated lampholders, special designs of shockproof hand-lamps, all-china switches, and a variety of other articles. A leaflet relating to small electric fans and sewing machine motors from the same firm is also to hand.

AMMETERS AND VOLTMETERS.—Messrs. Crompton & Co., Ltd. (Salisbury House, London, W., and Chelmsford), in a new catalogue just issued describe a pedestal form of instrument in cast-iron case, specially intended for mounting direct on ironclad controlling pillars or angle iron frameworks. The base of the instrument is in the form of a hollow neck, through which the leads can be brought, and terminates in a flange, which can be bolted down. Ammeters and voltmeters of both the moving-coil and moving-iron patterns are made up in this way.

MOTORS, CONTROLLERS, AND LAMPS.—A folding leaflet from the Electrical & Ordnance Accessories Co., Ltd., calls attention to a number of their manufactures, including motors, controllers, and arc and metal filament lamps.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

BOILER HOUSE SPECIALITIES.—We have received through the Engineers' Standardised Publications Association a series of leaflets from Messrs. Kater & Ankersmit (Centre Avenue, Acton Vale, W.). These describe an automatic air recorder for boiler furnaces, a series of oil separators suitable for exhaust steam, an oil pump, an oil filter, and a patent steam dryer and purifier.

CIRCUIT BREAKERS.—A new list is to hand from Messrs. Morris & Lister, Ltd. (Carlton Works, Lockhurst Lane, Coventry), embracing all the patterns of their now well-known time element circuit breaker, which is dependent upon thermal effects for its action. The different variations include plain overload with fixed or free handle, with or without no-voltage, minimum or reverse current attachments, and magnetic blow-out, all either open, protected, or totally enclosed.

CORONATION ILLUMINATIONS.—A special list of material for illuminations is to hand from G. Braulik (8 Lambeth Hill, E.C.). It includes the "Eclipse" and "Pixielite" forms of strip, a strip for small lamps with porcelain lamp-holders, a great number of illuminated devices, lamps at special prices, and a number of accessories.

ELECTRICAL DRIVING OF ROLLING MILLS.—A most attractively produced and well-illustrated pamphlet entitled "Electrically Operated Reversing Rolling Mills," is being issued by the Electric Construction Co., Ltd. (Dashwood House, 9, New Broad Street, E.C., and Wolverhampton). After a short introduction, the advantages of electrical driving are put forward, and the function and principle of power storage of the flywheel motor-generator are explained. A fully illustrated description is then given of the electrically driven reversing mills at the works of Messrs. Alfred Hickman, Ltd., in which continuous current rolling mill motors up to 6,000 h.p. capacity are in use.

New Motor Coaches on the Metropolitan Railway.—This railway has introduced two motor coaches of a new design with sufficiently powerful equipments to be used as locomotives, and sufficient accommodation to enable them to be also useful as individual units, for working a shuttle service between Baker Street and West Hampstead. According to the *Railway Gazette*, the cars have two first-class and two second-class compartments, luggage compartment, and drivers' cabins at both ends, and are 52 ft. long with two bogies each of 7 ft. wheel base. The total weight is 45 tons. One was equipped by the British Thomson-Houston Co., and the other by the British Westinghouse Co. Each car has four 150 h.p. motors, two on each bogie.

Hosted by Google

LOCAL NOTES

Aston: *Charge for Tramway Energy.*—The Birmingham and Midland Tramways Joint Committee have asked the Council to reduce the price of energy for the trams to 1d. per unit, but the Electricity Committee recommend the Council not to agree to this.

Belfast: *Cavehill and Whitewell Tramways.*—The arbitration proceedings for the purchase by the Corporation of the Cavehill and Whitewell trams have now been concluded.

The award has caused no little surprise in Dublin, for it has been fixed at no less a sum than £56,155, and the Corporation are to pay all the expenses of the arbitration. It will probably be remembered that a few years ago the Belfast Corporation promoted a Bill for purchasing the lines in question at £60,000, but it was rejected on second reading in the House of Commons on the ground that the price was excessive. It is computed that the terms of Mr. Lynden Macassey's award will involve the Corporation in a far larger sum, and the question of contesting the validity of the award has been suggested.

Brierley Hill: *Lighting Order Revoked.*—The Board of Trade have revoked the Brierley Hill electric lighting order granted in 1900.

Brighton: *Tramways to Worthing.*—In consequence of the promoters of the Brighton to Worthing Tramway scheme not having received the consent of several road authorities, the Standing Orders Committee of the House of Commons has refused to allow the Bill to go forward except as regards the portion of the proposed tramways between Lancing and Worthing. No announcement has yet been made as to whether the promotors will proceed with this smaller scheme.

Budleigh Salterton: *Electric Lighting.*—Mr. A. P. Trotter held an inquiry last week on behalf of the Board of Trade with regard to the objections which have been raised by a number of residents against the site of the proposed generating station. A gas-producer plant is to be used, and the objections seem to be based upon fears of unsightliness and noise. Mr. Trotter heard the views of the residents, and will report to the Board of Trade.

Guildford: *Lighting of Workhouse.*—A Consulting Engineer is to be appointed to advise with regard to the electric lighting of the workhouse.

Leeds: *Goods on Tramcars.*—The Tramways and Electricity Committee have passed a resolution expressing the opinion that the general carrying of parcels on tramcars is undesirable. The General Manager has prepared a report upon the subject, and the above is the Committee's conclusion.

London: *L.C.C. Tramways.*—A new tramway between Woolwich and Greenwich was inspected last week by Colonel Yorke on behalf of the Board of Trade, and has since been opened to the public.

When the first portion of the Council's tramways were reconstructed for electric traction on the conduit system no measures were taken to anchor the track rails, but in the case of the lines dealt with later extended yokes were used for this purpose. Many of the rails of the tramways first laid have begun to work loose, and it became necessary to anchor them by fastening short lengths of inverted rail to the track rails and embedding them in a concrete foundation. This work is now being extended to all trackwork laid without anchoring.

City of London: Linking up Electricity Works.—After considerable dispute as to the route to be followed, the City Corporation have at last agreed with the County of London Electric Supply Co. for the laying of a trunk main over London Bridge for the purpose of connecting up the Company's two stations in the North and South of London. It has been agreed that the work shall not be commenced until after the Coronation, and will then be carried on day and night.

Marylebone.—In reporting upon the need for additional battery capacity (see Tenders Received and Accepted), Mr. A. H. Seabrook, the Council's Electrical Engineer, states that the increased load this winter (1910–11) over the previous winter was 500 kw., and that he anticipates the additional load next winter will be at least 600 kw. over 1910–11.

Macclesfield: *Electricity Supply.*—A Board of Trade inquiry was held in Macclesfield last week to consider applications by the Electricity Company of Macclesfield, Ltd., and the Railless Electric Traction Co., Ltd., for an electric lighting provisional order for the district. The latter Company propose to supply electricity in conjunction with a service of trolley omnibuses, whilst the former are only proposing to supply electricity for lighting and power purposes. The trolley omnibus scheme is the subject of a Bill before Parliament, and consequently the Board of Trade can give no consideration to this. Therefore the Board will decide merely upon the merits of the two lighting schemes.

Newcastle; *Tramway Chairman Resigns.*—The Corporation having decided to transfer £12,000 from tramway profits to relief of rates in opposition to the general view of the Tramways Committee, the Chairman of the Committee has resigned as a protest.

Oldham: *Generating Costs.*—Considerable criticism has been made recently of the cost of producing electricity at the Corporation generating station, and Mr. S. W. Newington, the Borough Electrical Engineer, has prepared a report in which he deals with the matter in detail. Whilst the total cost of producing electrical energy at Oldham is within the average of a large number of similar size towns, yet it is admitted that the coal cost per unit is excessive. At the same time, the conditions under which the generating station at Oldham works must be taken into consideration, for there are no mechanical stokers; the coal has to be unloaded by hand, and the generating plant consists of reciprocating engine sets. The Electricity Committee have already decided to instal a turbo-generator, and have had under consideration for a long time the question of installing mechanical stokers and coal-handling plant.

Pontefract: *Transfer of Provisional Order.*—A Bill is to be promoted in Parliament to transfer the Council's Electric Lighting Order to the West Riding Tramways Co., Ltd. The transfer is subject to the Company paying £400, the estimated cost of the promotion of the Bill, and £140 already incurred in obtaining the provisional order. The Corporation will have the option of purchasing after twenty-seven years, no allowance being made for goodwill or monopoly value.

Worksop: *Overhead Wires.*—Application is to be made by the Council to the Board of Trade for sanction to erect overhead wires in certain parts of the town.

York: *Electricity Accounts.*—The accounts of the electricity department to March 31st show a net profit of £1,569 after meeting capital charges. It has been decided to place this surplus to the Renewal Fund.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Accrington.—Additional mains are to be laid at a cost of £1,830.

Barnstaple.—A recommendation of the Lighting Committee to replace the battery in the generating station at an estimated cost of £1,440, the loan for which is to be repaid in ten years, has been passed by the Corporation.

Derby.—It is proposed to instal three-phase generating plant at an estimated cost of £6,650. The plant will consist of two 500-kw. rotary converters, duplicate three-phase mains to supply Messrs. Rolls Royce's Works, transformers, and switchgear.

Haslingden.—A Local Government Board inquiry will shortly be held concerning a loan of £8,750 for electric lighting.

Luton.—The Electrical Engineer has made a preliminary report with regard to the provision of additional generating plant and mains. The estimated expenditure will be about £12,000.

Manchester.—A 350 kw. static transformer is required by the Electricity Committee. Particulars from the Secretary, Electricity Department, Town Hall, and tenders to Chairman of Committee by April 11th.

St. Helens.—A 1,500 kw. turbo-alternator, with condensing plant and switchgear, is required by the Electricity Committee. Particulars from the Borough Electrical Engineer, and tenders to Chairman of Committee by April 20th.

South Africa.—The scheme of electric supply in Potchefstroom has not been approved by the Government, and a new scheme at an estimated cost of £13,000 is being prepared.

Stoke-on-Trent.—Additional feeders are to be laid in Burslem at a cost of £700.

Torquay.—The Borough Electrical Engineer recommends extensions to the generating plant at an estimated cost of £5,000. The new plant will include a turbo generating set.

Turkey.—According to the *Board of Trade Journal*, the Turkish Ministry of Public Works at Constantinople is in-

Hosted by Google

viting tenders for a concession for electric lighting and tramways in Jerusalem. A copy of the specification may be seen by British contractors at 73 Basinghall Street, E.C.

Worcester.—The Electricity Committee recommend the installation of additional generating plant at a cost of £7,100.

Wrexham.—A loan of £800 is to be taken up for the provision of a traction battery with switchboard and reversible booster.

York.—The Electricity Committee propose to instal a new battery, booster, regulator, and other machinery at an estimated cost of £1,400.

WIRING

London.—New theatre, Broad Street, Holborn.

PROVINCES.

Aberdeen.—Flax stores in Maberley Street for Messrs. Richards, Ltd.

Barnsley.—Boys' School at Churchfield. Architects, R. & W. Dixon, 5 Eastgate.

Birmingham.—Council School at Small Heath.

Bristol.—Additions to Cadbury Heath Council School. Architect, R. S. Phillips, Shire Hall, Gloucester.

Carnarvon.—Hospital in connection with the workhouse.

Coventry.—Additions to the Coventry and Warwickshire Hospital.

Leeds.—Extension to General Infirmary.

Oxford.—New County Hall.

Scarborough.—New Drill Hall and Headquarters, Royal Field Artillery (Territorials).

St. Albans.—Vicarage at St. Paul's Church. Architects, Messrs. Cutts, 14 Southampton Street, London.

MISCELLANEOUS

Australia.—The Deputy Postmaster-General at Melbourne invites tenders by May 16th for 10,000 telephone protectors.

Blackpool.—Application is to be made for a loan of £2,000 for the equipment of additional trams with top-deck covers.

Hornsey.—Tenders are invited by April 24th for the supply and erection of flame arc lamps. Particulars from the Borough Electrical Engineer.

Japan.—The Japanese Government have decided to instal a telephone system in Korea.

London.—Tenders are invited by H.M. Office of Works for a supply of wood blocks for conduit boxes for a period of three years. (See an advertisement on another page.)

Manchester.—Tenders are invited by April 18th for steel tramway poles and span wire brackets. Particulars from Tramway Manager.

New Zealand.—The *Board of Trade Journal* states that a New Zealand municipality proposes to raise a loan of £24,000 for the construction of additional tramways. Further particulars may be obtained at 73 Basinghall Street, London, E.C.

Spain.—The *Board of Trade Journal* states that extensive harbour improvements, which include the installation of sixteen electric cranes, are to be carried out at Barcelona, Valencia, Algeciras, Seville, Santander, Bilbao, Canary Islands (La Luz and Teneriffe), Melilla, and Ceuta.

TENDERS RECEIVED AND ACCEPTED

Chesham.—The local Electric Lighting Co. is to be asked to continue the public lighting for two years.

Ilford.—A contract for electricity meters has been given to the Electrical Apparatus Co., Ltd.

London: *L.C.C.*—The Highways Committee have received tenders for the supply of four electric watering-cars and four electrical equipments for same, but, after consideration, report that it will not be in the best interests of the Council to accept any of the tenders submitted.

Marylebone.—The tender of the Tudor Accumulator Co., Ltd., for the provision of additional cells to the Manchester Square and Rathbone Place Sub-station batteries at £2,643, plus £156 per annum for maintenance for a period of twenty years, is recommended for acceptance.

York.—The tender of the British Thomson-Houston Co., Ltd., has been accepted for a 1,000-kw. turbo alternator, with converters and switchgear at £7,451, and that of Messrs. Babcock & Wilcox, Ltd., for a water-tube boiler, automatic stoker, and pipework at £2,080. The tender for electricity meters up to 5 amperes capacity has been given to the Electrical Apparatus Co., Ltd.

OSRAM·LAMPS

APPOINTMENTS AND PERSONAL NOTES

Mr. J. W. Meares, Electrical Adviser to the Government of India, will arrive in England on leave in a few days' time. Letters addressed c/o Messrs. H. S. King & Co., 65 Cornhill, London, E.C., will be forwarded.

Mr. A. S. Giles, formerly Electrical Engineer to the Blackburn Corporation, and latterly in charge of the Cape Town Tramways, has been appointed to the General Managership of the Lisbon Tramways.

The Accrington Council have appointed Mr. Ernest Hall shift engineer at the Electricity Works at £104 a year.

Mr. J. L. Winter, who has acted for three years as Chief Assistant Engineer to the Musselburgh and District Electric Light and Traction Co., has been appointed Manager of the Bo'ness Electricity Works.

Arrangements are being made to give a farewell dinner on May 6th to Mr. Evan Parry (late Chief Assistant to Mr. H. F. Parshall, M.Inst.C.E.), prior to his departure to New Zealand to take up his new appointment of Electrical Engineer to the New Zealand Government. Those who would like to be present are requested to apply to Mr. E. Moss (801 Salisbury House, London Wall, E.C.).

Mr. H. F. Parshall has been appointed Chairman of the Central London Railway in place of Sir Henry Oakley, who has just resigned that position.

Mr. F. T. Chapman has been appointed to succeed Professor Buchanan as Lecturer in electro-technics at Faraday House. He formerly held an appointment at the Leeds Technical School, and for the last ten years has been designer to Messrs. Greenwood & Batley, of Leeds.

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £56 15s. to £57 per ton (last week, £56 15s. to £57 5s.).

Electric & Ordnance Accessories Co.—The Hurst Electric Manufacturing Co., Clokey's Buildings, King Street, Belfast, have been appointed representatives in Ireland for the Electric & Ordnance Accessories Co., Ltd.

Plant for Sale.—The Bristol Electricity Committee have for sale a quantity of plant, including engines, alternators, motors, 100 arc lamps, electric launch, &c. (See an advertisement on another page.)

Liquidations.—Before Mr. Justice Swinfen Eady on Tuesday an application by Messrs. Siemens Bros. Dynamo Works, Ltd., for the compulsory winding-up of Arc Lamps, Ltd., was allowed to stand over for a week. It is considered probable that a scheme for the payment of creditors will be arranged.

Messrs. F. A. Glover & Co., Ltd., Vine Street, Clerkenwell, are to be wound up voluntarily. The liquidators are W. Peet, 27 Queen Victoria Street, E.C., and G. E. Corfield, Balfour House, Finsbury Pavement, E.C. A meeting of creditors will be held on April 13th at 4 p.m. at 27 Queen Victoria Street, E.C.

The British Radio-Telegraph and Telephone Co., Ltd., is to be wound up voluntarily. Mr. G. P. Grenfell, 5 London Wall Buildings, E.C., is liquidator. A meeting of creditors will be held at the offices of Messrs. Hudson, Matthews & Co., 32 Queen Victoria Street, E.C., on April 13th at 2.30 p.m.

Westinghouse Turbines.—The British Westinghouse Co., Ltd., report great activity in their steam-turbine department. The output of these machines during 1910 aggregated 100,000 h.p., or more than double that in 1909. During the first three months of this year the Company received orders for twenty-two impulse turbines aggregating 40,000 h.p., equivalent to an increase of nearly 60 per cent. on the figure for the corresponding period of last year.

Change of Address.—The Dowsing Radiant Heat Co., Ltd., has removed from 24 Budge Row, Cannon Street, E.C., and opened showrooms and offices at 105 Great Portland Street, W., where larger and more commodious premises are available.

Adams Agents.—The Adams Manufacturing Co., Ltd., advise us that their agreement with their Scottish Agent having terminated, they have, for the convenience of their customers throughout Scotland (except Midlothian), opened an office at 50 Wellington Street, Glasgow, where their Resident Engineer, Mr. A. L. Birch, is prepared to supply all information. For Midlothian the Company's Agents are Messrs. Mitchell, Graham & Son, 46 Buccleuch Street, Edinburgh.

Hosted by Google

PARLIAMENTARY INTELLIGENCE

ACTON ELECTRICITY UNDERTAKING.—The Bill of the Metropolitan Electric Supply Co., enabling it to purchase the electricity undertaking of the Acton Urban District Council, was passed by a Committee of the House of Commons, presided over by Sir Henry Kimber, last week. The company proposes to take over the undertaking, to pay the capital charges on the outstanding loans, and also to make a payment of £5,000 to the Council as purchase money. The Bill, although unopposed, was sent to a Select Committee for consideration in the usual way, and leave was given to the Acton Council of Public Welfare to appear before the Committee. The point made on behalf of this body was that the agreement to sell the undertaking to the company was passed by a very small majority on the Council, and that when the poll of the ratepayers was taken, only a few days were allowed for the result to be obtained. Further, it was argued that the company should pay, say, £20,000 or £30,000 for the goodwill of the undertaking. The Committee, however, decided to pass the preamble of the Bill without alterations.

CENTRAL LONDON RAILWAY BILL.—A Committee of the House of Commons passed the Central London Railway Company's Bill last week. The Bill proposes to extend the company's line from the Wood Lane terminus to join the authorised Ealing and Shepherd's Bush Railway of the Great Western Railway Co., thus allowing a through service from Liverpool Street (when that extension is complete) to Ealing. The Great Western Railway Co. have an old agreement with the Metropolitan Railway Co., which, it was claimed before the Committee by the latter, would be prejudiced by the proposals in the present Bill, and the Committee ordered words to be inserted in the Bill with the object of safeguarding the terms of this agreement.

WINCHESTER ELECTRICITY UNDERTAKING.—The Bill of the Winchester Corporation authorising the purchase of the undertaking of the Winchester Electric Lighting Power Co., was passed last week by a Committee of the House of Commons. The parties have agreed to the purchase price being fixed at £91,000, plus the repayment of capital expenditure, and the Committee allowed forty years for repaying the loan to provide the purchase price and twenty years for any new capital that may be borrowed in the future. This case involved an interesting point with regard to the company's wiring and fitting business, which had been developed to a considerable extent. The Corporation originally intended to resist having to purchase this, but eventually an agreement was come to on the point. The Winchester Gas Co. opposed the terms of the sale, and the Committee inserted the Northumberland Clause, under which the Council must, at the beginning of each year, fix the charges for supply at such a figure that there will be no loss upon the year's working.

SIDMOUTH GAS & ELECTRIC BILL.—The Bill of the Sidmouth Gas & Electricity Co., which confers electric lighting powers upon the existing gas company, was passed by a Committee of the House of Lords last week.

"The Generators."—At 7.30 p.m. to-morrow, the 66 generators will start on a five hours' run at full load, the trial being for endurance and consumption. The site selected is the Caledonian Salon of the Holborn Restaurant.

Obituary.—We regret to announce the sudden death at Bournemouth, on the 28th ult., of Mr. J. Hardie McLean, Manager and Engineer of the Midland Electric Corporation for Power Distribution, at the age of forty-four. After serving his apprenticeship with Mr. Greenhill at Belfast he became associated with Mr. Ferranti's staff at the Grosvenor Gallery and Deptford stations, where he went through the hardest of pioneering work of the early days of electrical supply. From Deptford he went to Oxford, where he put down the "Oxford" system, and managed the Company with success, afterwards becoming a partner in the old-established Oxford firm of W. Lucy & Co. Later he became General Manager and Engineer to the Midland Co., and it was a great satisfaction to him that the year just closed saw the financial success of this Company firmly established.

The Batti-Wallahs.—This society, erstwhile the P. & O. Batti-Wallahs (for the sake of the uninitiated we should explain that Batti-Wallah means "the Light-Man"), held its annual general meeting at the Golden Cross Hotel, Charing Cross, on Wednesday, the 29th March. There was a fair attendance of members. The secretary reported that 44 new members had been enrolled during the year, and that the total membership was now 164. The report and balance sheet were passed, and the usual formal business transacted. The following were elected as officers and committee for the year:—President, W. Slade Olver; vice-presidents, C. Newton Russell, W. A. Jones, and F. J. Collis; hon. secretary and treasurer, J. F. Avila; assistant hon. secretary, Mr. R. J. Elmshurst; entertainment hon. secretary, Mr. A. W. Robinson; members of committee, Messrs. M. R. Gardner, C. C. R. Wray, W. Dobson, J. S. Huddleston, F. J. Humphrey, and R. Ball. The last fortnightly gathering of the society for the season will take place on Wednesday, 12th April, at the Bedford Head Hotel, in Tottenham Court Road, W.C. A smoking concert was arranged for Friday, 21st April, but it has been proposed to postpone this for a week until the 28th April.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

O. C. Hawkes.—There was a net profit of £6,216 for 1910, of which £5,103 is available for dividends. After meeting the 5 per cent. preference dividend, the sum of £853 is carried forward.

Gateshead & District Tramways Co.—The profit for 1910 amounts to £22,149, and after placing £4,500 to reserve and meeting reduction of mortgage and preference dividends, a dividend at the rate of 6 per cent. per annum is declared upon the ordinary shares, carrying forward £848.

Clyde Valley Electrical Power Co.—At the annual meeting last week it was stated that the continued expansion of the company's business had rendered it necessary to order an additional 5,000 k.w. turbo-generator for the Motherwell power station. This brings the total capacity of the company's two-power stations to 22,600 k.w.

Newcastle Electric Supply Co.—At the annual meeting last week Dr. J. T. Merz stated that although the profit for 1910 was £5,000 more than for the previous year, the profit per horse-power had fallen from 16s. to 14s. 6d.

Metropolitan Electric Tramways.—The report for 1910 shows a net profit of £57,345, and after meeting preference dividend and placing £8,000 to reserve, a dividend of 5½ per cent. for the year is declared upon the ordinary shares. The sum carried forward is £2,822. The total length of the Company's tramways and light railways is now 55½ miles. The renewals account now stands at £83,358. The number of passengers carried last year was 76,460,980 compared with 62,357,947 in the previous year, the average receipts per car mile being 10·78d. against 11·13d.

North Metropolitan Electric Power Supply Co.—A dividend of 6 per cent., with a bonus of 3s. per share, making 15s. per share, has been declared upon the ordinary shares for 1910. The sum of £2,000 has been placed to reserve for redemption of debentures and £21,639 to depreciation. The sum carried forward is £1,065.

Hastings and District Tramways Co.—A general meeting will be held shortly to consider a proposal for the reduction of this company's capital.

Central London Railway Co.—An issue of £385,000 4½ per cent. Preference stock is being made in connection with the extension of the Company's line to Liverpool Street.

Durham Electrical Power Distributing Co.—In spite of an increased number of consumers, the profits for 1910 were less by £2,295 than in 1909, with the result that only 3¾ per cent. has been paid upon the 5 per cent. Preference shares. The Company experienced a bad time in 1910 owing to the unsettlement in the coal trade. For the first twelve weeks of 1911, however, there has been some improvement, although at present there are no signs of a considerable increase in trade.

Anglo-Argentine Tramways.—A final dividend, making 7¾ per cent. for the year, is declared upon ordinary shares for 1910, carrying forward £13,045.

British Westinghouse Engineers' Club.—The fifth annual dinner of this club was held on Friday evening, March 31st, 1911, in the Banqueting Hall of the Midland Hotel, Manchester, when a company of over 170 members of the staff assembled. Mr. J. S. Peck was in the chair, and an excellent musical programme was provided. Mr. W. W. Blunt, the general sales manager, proposed the toast of the Company, and mentioned that the Company's sales for this year were much in excess of those in the corresponding period of last year. Mr. C. A. Park, the recently appointed managing director, responded. Mr. D. N. Dunlop, speaking on behalf of his colleagues of the sales organisation, expressed appreciation of the appointment of their general sales manager, Mr. W. W. Blunt, as a director of the Company, which was suitably acknowledged in a short speech by Mr. Blunt. The toast of the Works Organisation was proposed by Mr. O. H. Baldwin, and Mr. Ph. A. Lange, managing director of the works, in responding, mentioned that while the works had an extremely heavy load to carry in consequence of the large increase in orders, he was fully confident that they would be able to meet all demands made upon them. The toast of the Engineers' Club and the Foremen's Association was proposed in a humorous speech by Mr. A. McKinstry, responses being made by Mr. J. S. Peck for the engineers and Mr. R. W. Rowe for the foremen.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published March 30th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

9,933/10. **Insulating Compound.** R. G. SHARP. A filling for cable troughs consists of pitch and an equal quantity by weight of finely ground whinstone or granite. The two substances are well mixed together when the pitch is in a molten condition.

11,792/10. **Non-arcing Cable.** C. J. BEAVER, G. L. PREECE, and E. A. CLAREMONT. A cable suitable for mines where external arcing is dangerous has two layers of steel wire armouring or lead sheathing between which is a layer of fireproof material such as asbestos or treated fibrous material. One figure.

13,406/10. **Motor Starter.** ADAMS MANUFACTURING CO., LTD. (*Cutler Hammer Mfg. Co., U.S.A.*). This is a combined starter and shunt regulator with an adjustable automatic device for arresting and holding the arm in the position corresponding to any desired speed. Three figures.

14,743/10. **Resistance Wire.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). An alloy which can be rolled and drawn and is suitable for resistance wire or heating elements consists of 20 parts by weight of iron, 62 parts nickel, 12½ parts chromium, 5 parts manganese, and between 0·1 and 0·4 per cent. of carbon. This alloy oxidises only very slowly at a red heat.

15,424/10. **Metal Filament Lamps.** F. HARRISON. The stem is constructed in two parts, and the distance between the two sets of radial supporting arms can be varied by sliding the parts relatively to each other. Four figures.

21,339/10. **Regenerative Control.** JOHNSON-LUNDELL ELECTRIC TRACTION CO. (*R. Lundell*). Two series motors on a common load are controlled by series-parallel connection, and a battery and resistance are connected across each series field to give an independent control of the fields. Six figures.

Opposition to Grant of Patents

28,210/09. **Advertising Sign.** A. W. LEONARD. This patent has been allowed in spite of opposition. It covers an electrically driven and illuminated advertising device in which transparent advertisements are exhibited successively through apertures in a box.

29,938/09. **Coal Conveyor.** J. NISBET and J. KIRKPATRICK. This patent has been granted in spite of opposition. It covers a coal-face conveyor comprising a number of bogies, which are tilted to discharge the coal when on a bridge at the roadhead.

Amendments

23,077/04. **Electric Welding.** L. S. LACHMAN. Pontelec Welding Patents, Ltd., desire to amend this specification, which covers a process of electric spot welding for sheet metal articles. The proposed amendments consist of the insertion of a reference to Ferranti's patent No. 11,921/03 and other disclaiming notes. (See also ELECTRICAL ENGINEERING, Dec. 22nd, 1910, and March 30th, 1911.)

13,276/04. **Protective Devices for Transformers.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). The amendments to this specification referred to in ELECTRICAL ENGINEERING, Vol. VI., p. 812, have been allowed, and certain further alterations have been made. The patent covers tripping coils which operate on a change of the normal ratio of current in-put to out-put.

29,895/09. **Submarine Signalling.** S. M. DAVISON desires to amend this specification in order to define more clearly the features of invention. The patent describes a system of signalling by sound waves under water by means of an electrically operated bell and a telephonic receiver.

8,219/10. **Train-lighting Dynamo.** H. LEITNER. A disclaiming reference to patent No. 16,447 of 1909 has been inserted in this specification, which covers the use of broad brushes in reversible variable-speed dynamos in order to produce a strong cross-magnetising field from the armature.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: BLECKLY [Multiple carbon lamp] 6,536/10; BURKITT 8,380/10; VINCENT [Vapour lamps] 13,405/10.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: BRITISH THOMSON-HOUSTON CO. [Distribution systems] 13,124/10; ANDERSON, RUSSELL and GRAY [Distribution systems] 15,618/10.

Dynamos, Motors, and Transformers: HALL [Motor-car lighting] 6,312/10; VON ZWEIGBERGK [Machines] 6,624/10; LORING [Homopolar machines] 6,634/10; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Control and protection of motors] 13,123/10, and [Machines] 13,410/10; SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke Ges.*) [Cooling of machines] 20,491/10; MACDONALD [Motors] 29,593/10; MAXWELL [Squirrel-cage motors] 4,871/11.

Electric Ignition: HART (*Bawden*) [Ignition of fuses] 15,098/10; GILLIES and MCPHEE [Blasting fuses] 17,789/10.

Electrometallurgy and Electrochemistry: STORA KOPPARBERGS BERGSLAGS AKTIEBOLAG [Electric furnaces] 6,768/10; WILDERMANN [Electrolytic cells] 26,568/10.

Incandescent Lamps: BLOXAM (*Siemens & Halske A.-G.*) [Manufacture of tungsten filaments] 19,932/08; GRAINGER [Lamps and filaments] 18,799/09; HARRISON, 10,874/10; SKAUPY [Metal filament lamps] 15,621/10; SCHROTER [Metal filament lamps] 23,121/10.

Instruments and Meters: HARTMANN & BRAUN A.-G. [High-frequency resonance measuring instruments] 14,925/10.

Switchgear, Fuses, and Fittings: WATERHOUSE [Pendant fittings] 6,595/10; HIGHFIELD [Ceiling roses, wall-plugs, &c.] 7,929/10; CHADWICK and CLARKE [Detachable handle for controllers] 11,569/10; LAITTE and SAFETY LIGHT, LTD. [Switch] 12,347/10; GOOD [Sign flasher] 13,293/10; KALLMANN [Motor starters] 14,186/10; FAIRWEATHER (*Hart Manufacturing Co.*) [Switches] 18,344/10.

Telephony and Telegraphy: FAIRWEATHER (*Stein*) [Sub-station telephone] 22,410/10.

Traction: STEVENS [Signalling apparatus] 6,006/10; PECKHAM and ANDREWS [Railway and tramway tracks] 6,732/10; MOORE [Switches operated by passing trains] 15,564/10; SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke Ges.*) [Control apparatus for traction supply at two voltages] 17,995/10.

Miscellaneous: DONISTHORPE [Synchronising apparatus] 3,512/10; DE FERRANTI [Packings for turbo-blading] 7,089/10; DE HOLDEN-STONE [Electric generation and superheating of steam] 8,005/10; BRAGGE [Dust distributor for mines] 12,360/10; ENGEL [Contact device] 15,150/10; JOH and WOLF [Utilising heat of sun] 26,782/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Electric Ignition: JUSTON and BÜNZLI [Magneto generator] 28,177/10.

Electrochemistry, &c.: OTTO [Liquid sterilising apparatus] 4,127/11; HELFENSTEIN [Electric smelting furnace with refining hearths] 5,140/11; ESTELLE [Anodes for use with alkaline salt solutions] 5,734/11.

Traction: TH. GOLDSCHMIDT [Rail welding] 26,085/10; GARDNER [Cleaning track] 1,597/11; HILL [Automatic train control system] 5,378/11.

Miscellaneous: CLAUDE [Vacuum tube lighting] 5,589/11; RITTER and UHLMANN [Lamp-shades] 6,081/11.

The following amended Specifications can now be obtained.

A. M. TAYLOR [Storage battery plant] 24,643/08; H. A. MAVOR and MAVOR & COULSON, LTD. [Electrical marine propulsion] 27,478/09.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

9,457 of April 13th, 1897. **Transformers.** A. F. BERRY. This patent relates to the well-known Berry transformer and covers the formation of each radial rectangular section of straight strips of thin sheet iron with alternate strips overlapping at the ends so as to form interleaved joints. The expiration of the fundamental patent, No. 2,801 of 1897 was referred to in ELECTRICAL ENGINEERING.

9,464 of April 13th, 1897. **Rubber Compositions.** E. HORNUNG and S. HANSEL. Compositions containing india-rubber or gutta-percha are prevented from hardening on exposure to air or heat by adding a mixture of insoluble gelatine or glue with vulcanised oil, and afterwards vulcanising.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: M. VON RECKLINGHAUSEN [Automatic tilting of mercury vapour lamps] 25,749/05.

Electric Ignition: G. GIORGI [Electromagnetic control and ignition of gas jets] 27,297/04.

Electrometallurgy, &c.: S. O. COWPER-COLES [Electrolytic manufacture of copper wire and strip] 26,724/98.

Incandescent Lamps: G. MICHAUD and E. DELASSON [Filaments of magnesia, alumina, &c.] 27,707/04.

Instruments, &c.: C. RAMSPECK [Prepayment meter mechanism] 26,264/98.

Switchgear, &c.: O. O. KRUH [Mercury vapour arc rectifiers] 27,011/04; M. J. E. TILNEY [Automatic voltage regulator] 27,168/04; J. H. ROSS [Lamp-shade carrier] 26,202/05; M. B. FIELD and FERRANTI, LTD. [Prevention of chattering of A.C. electromagnets] 26,281/05.

Telephony, &c.: E. RAYMOND-BARKER [High-speed telegraphy] 25,866/05.

Miscellaneous: A. J. BOULT (*H. Joly*) [Electrical synchronising of phonographs and cinematographs] 26,522/05.

SUMMARY

THE Paper by Mr. J. E. Taylor, of the General Post Office, read before the Institution of Electrical Engineers on Thursday last, is a very complete account of the various interferences and disturbances met with in wireless telegraph working, and contains many valuable suggestions for avoiding these. In the discussion of the Paper, Commander Loring, of the Post Office, gave the results of a number of investigations into the matter, and Sir Oliver Lodge and Mr. W. Duddell discussed the use of unearthed aerials and the effects of different types of wave trains. (Page 187.)

THE chief features of the electrical installation of the Royal Automobile Club are the thoroughness of the wiring work, the artistic quality of the fittings, and the agreeable and efficient nature of the illumination. We illustrate some of the fittings, which were specially designed. All the cables were pushed into the screwed steel conduit and not drawn. Two independent supplies are provided, and the wiring is in duplicate, each room having lights off both supplies. A highly ingenious fire-alarm system is provided, and all the corridor and staircase lights are switched on when an alarm of fire is given. The power equipment includes lifts, ventilating fans, pumps for the swimming bath, and a sewage raising plant, and comprises 34 motors in all. (Page 189.)

MR. JUSTICE JOYCE gave judgment last week in the action by the London Electric Supply Corporation against the Westminster Electric Supply Corporation. He held that the Westminster company had, to all intents and purposes, purchased the Westminster undertaking of the London Electric Supply Corporation, and that no breach of the agreement between the two parties has taken place. (Page 190.)

OUR monthly article on new electrical supplies and accessories includes illustrations of a number of new designs of holophane shades and some fittings for use with them. We also describe the latest form of the "Twinob" switch, some new motor starters and motor panels, and a recently introduced pattern of electric iron. (Page 191.)

MR. C. C. F. MONCKTON contributes an article commenting on Mr. Taylor's Paper, and describes a method of reducing interference in use at Trinidad, and at the same time improving the signals by connecting two receiving transformers of unequal coupling in parallel. (Page 193.)

MR. JUSTICE PARKER has reserved his decision as to the extension of the Lodge wireless patent until after the Easter vacation. He has expressed a wish to assist the Lodge-Muirhead Co., but says he will not grant the extension if the company are going to press their rights under the patent too far. (Page 193.)

A NEW form of fault localising set for making the Murray loop test, requiring no correction for the connections to the slide wire, has been introduced by R. W. Paul. (Page 194.)

A LETTER from Simplex Conduits, Ltd., calls attention to the high efficiency of heaters of the immersion type. The discussion on meters is also continued in our correspondence columns by a representative of a firm making commutator meters. Mr. J. T. Irwin has also sent us an interesting communication dealing with the influence of harmonics of high frequency in the current wave upon the accuracy of alternating current meters. (Page 195.)

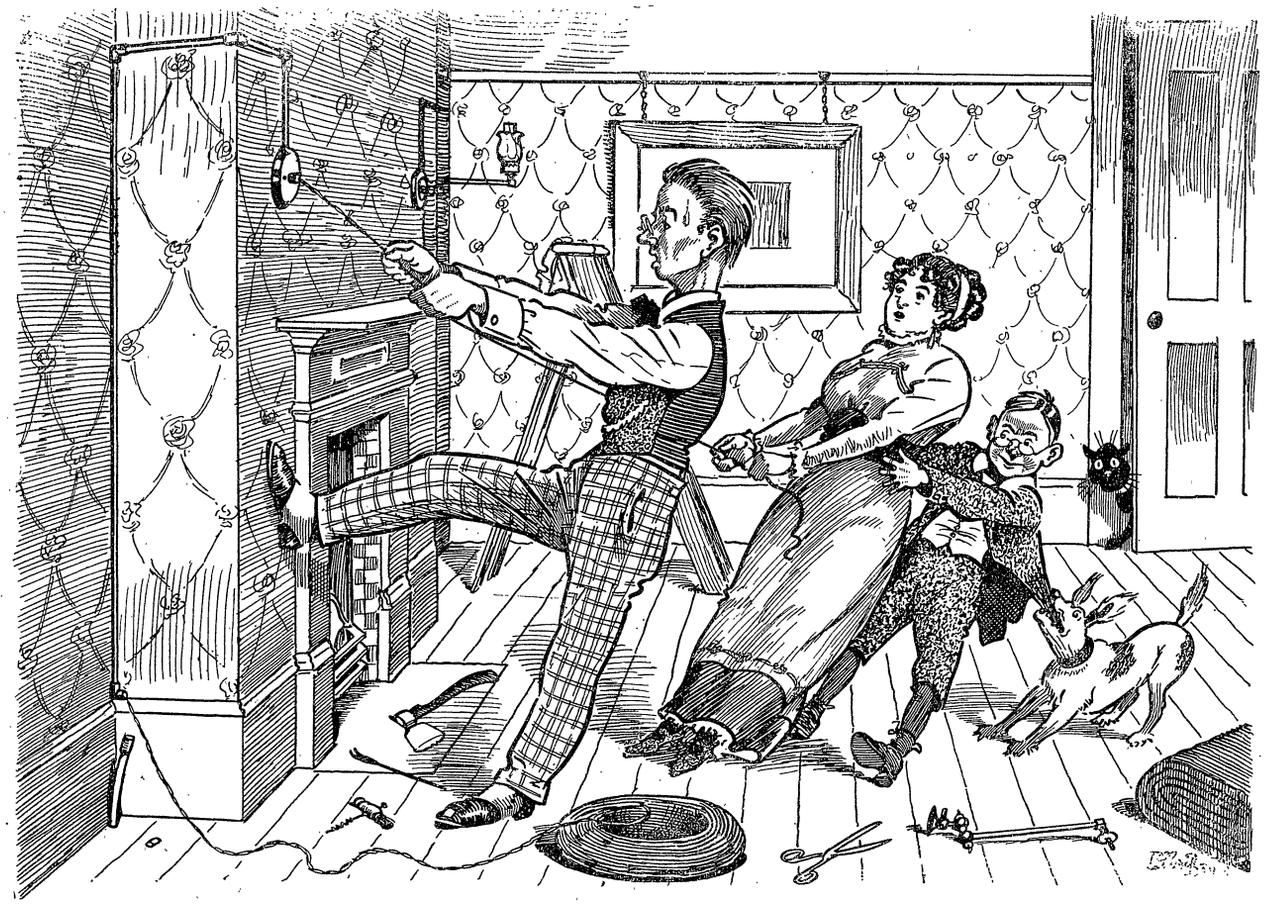
Among the specifications published by the Patent Office on Thursday last was one by Siemens & Halske for a process of manufacturing drawn tungsten filaments by first making a ductile alloy of tungsten with nickel. A method of cooling armatures by circulating water through the core is covered by Siemens Bros. Dynamo Works, and H. Maxwell describes end connections for squirrel-cage rotors, doubled back upon themselves to give resistance with minimum self-induction. A patent by B. J. Hall for an arc-lamp photo-printing apparatus, and another by A. Kapteyn for the emergency operation of pneumatic brakes, expire during the current week, after the full life of fourteen years. (Page 196.)

In a Paper read recently before the Dublin Local Section of the Institution of Electrical Engineers, Mr. S. L. R. Price advocated the use of electric heaters of large surface similar in construction to hot-water pipes. (Page 197.)

In a lecture at the Royal Society of Arts, on domestic electric heating and cooking apparatus, Dr. J. A. Fleming compared their efficiency with that of gas. The cost of cooking was probably equal with electricity at 1d. per unit and gas at 2s. 9d. For heating small rooms there was probably a saving with electricity at ¾d. per unit. (Page 198.)

The Scarborough tramways have resumed running, and the Corporation have withdrawn their application to the Board of Trade to deal with the company.—A new 1,000 k.w. Westinghouse turbo-alternator has been put into operation at St. Helens.—The A.C. supply from the Leeds tramway power station is to be converted to 50 periods, uniform with the supply from the lighting station.—Mr. Albert Gay, the Islington Borough Electrical Engineer, has been asked to advise the Barnstaple Corporation.—A net profit of £8,680 was made upon the Southend electric supply department last year, and £5,100 upon the tramways. (Page 198.)



A 3,000 k.w. turbo-alternator is to be installed at Bradford, and rotary converters, cables and switchgear at Derby; car traversers are required by the L.C.C.; electric cables, fittings, &c., by the Dudley Corporation; extensions are contemplated at Blackburn, Epsom, Newcastle-under-Lyme, and South Shields.—Electric lighting schemes are under consideration at Barmouth, Oulton Broad, and Woodbridge. (Page 199.)

The capital of the Hastings and District Tramways Co. is to be reduced from £500,000 to £372,942 10s. —The expansion of traffic upon the Metropolitan Electric Tramways, Ltd., last year was so great that cars had to be hired. (Page 200.)

The Telephone Purchase.—As we have already announced, the Postmaster-General and the National Telephone Co. have disagreed as to the suitability of certain of the company's plant for the purposes of the forthcoming transfer, and the matter has to go before the Railway and Canal Commissioners for arbitration. The Postmaster-General was recently given leave to put certain interrogatories or questions to the company regarding the matter, which the latter resent on the ground that at the present stage of the proceedings it placed an undue burden upon them in relation to matters of detail. An appeal by the company to the Railway and Canal Commissioners on this point last week was successful.

Electricity in Agriculture.—According to the *Standard of Empire*, the Hon. Adam Beck has been sent to Europe by the Canadian Government to study the application of electricity to farming operations.

In the House of Commons last week Mr. Charles Bathurst asked the Parliamentary Secretary to the Board of Agriculture whether, in view of the value of the experiments of Professor Priestley of Bristol University (see Electrical Engineering, April 6th, p. 179), as to the effect of the discharge of positive electricity on the acceleration of plant growth, the Board could increase their present grant of £50. In reply Sir E. Strachey stated that a general scheme for the promotion of agriculture research was now under consideration, and that funds would, no doubt, be available for the purpose referred to.

Mr. Flecks, who is wiring his house for Electric Lighting, sees no object in erecting new pipes to take the wires, as he can utilise the existing gas pipes.

INTERFERENCES IN WIRELESS TELEGRAPHY

ON Thursday last a Paper was read at the Institution of Electrical Engineers by Mr. J. E. Taylor, of the General Post Office, entitled "Wireless Telegraph Working in Relation to Interferences and Perturbations." After emphasising the importance, especially in the case of coast stations, of freedom from disturbances, and referring to the almost universal employment of telephonic receivers, the author divides the different disturbances as follows: Extraneous noises, local induction influences, waves from other stations, atmospheric electrical perturbations, and perturbances of wave-propagation efficiency of the dielectric medium. The first trouble is avoidable by careful selection of the site of the station, &c., and the second can be eliminated by ensuring that there is no sparking at the various contacts in the adjacent telegraphic circuits, no electrostatic or electromagnetic induction from these circuits, nor battery leakage. Telegraph or telephone circuits should be led into the station by underground cable, so that the exposed line is at least 30 or 40 yards distant; twin wiring should be employed, and the wireless and land line earths should be some distance apart.

The whole question of tuning and selectivity is involved in the third trouble, which may be sub-divided as follows: Electrostatic interference; pre-charged aerial interference; interference by heavily coupled transmitters; interference by lightly coupled transmitters; interference between continuous wave and spark systems; interference by accidental waves; and damping in transmitters and receivers in relation to interference. The first item is due to electrostatic induction across from aerial to aerial in the cases of stations close together. This produces forced oscillations, which are extremely difficult to annul. The trouble is more pronounced from aerials which are charged up to a high potential prior to the discharge across the spark-gap—*i.e.*, from pre-charged aerials, such as the Lodge-Muirhead, as compared with coupled transmitters as employed by Marconi. The interference by pre-charged aerials on distant stations is most difficult to tune out, and is doubtless due to the character of the wave-train emitted. Heavily coupled transmitters give rise to interference both in respect of impurity of wave-train due to forcing at the transmitter, and also in respect of double-wave emission. The former trouble is particularly pronounced in the case of continuous-wave and even quenched-spark transmitters, unless they are so connected as to reduce the damping in the aerial system to a sufficiently small amount. A high degree of selectiveness is assured with lightly coupled transmitters, and the accompanying reduction in range can be largely compensated by sharply tuning the receiver. For ship and shore communication, however, a very light coupling is impracticable by reason of the reduction of range and the difficulty of getting into touch with sharp tuning. A moderate bluntness of tuning is therefore essential for such work, but there is no reason why coast and ship stations should not have "stand-by" and "tune" adjustments for both receivers and transmitters, the former being used for calling and look-out purposes only. There is reason to suspect that with continuous wave or so-called "undamped" systems there is not the high degree of immunity from interference which might be expected. This is due, probably, to the "forcing" action of such transmitters, as any one oscillation must be appreciably damped affecting the purity of the wave-form. Interference produced by emission of accidental waves occurs if insulated sections of the aerial stay wires are allowed to spark to ground or to one another as a result of the electrostatic induction set up. When it occurs, the conductors emit waves of a period determined by their own electrical constants.

Turning to the question of damping in relation to interference, Mr. Taylor refers to the deformation of waves due to increased "driving" of energy into the oscillator to maintain the oscillations, and mentions that a moderately damped receiver is not nearly so sensitive as a very slightly damped one. He then describes in detail the operation of the Marconi "multiple-tuner," which comprises three coupled tuned circuits, enabling the use of variable coupling, while providing an intermediate circuit of very small damping. Without its use, since both the detector and aerial circuits possess considerable damping coefficients, it would not be feasible to reduce the coupling considerably and still preserve signals of readable strength. Another method of reducing interference is by the use of divided circuits, in which the impulses in one branch are annulled by those in the other, except to the extent necessary for the interpretation of the signals. In S. G. Brown's "bridge" connection the aerial is connected through capacities to both ends of an inductance, across which is connected the detector. The inductance is earthed at some point in the middle, and by altering this point the detector is affected by the branch best tuned to the received impulses. The author considers, however, that the adoption of non-earthed directive aerials promises more satisfactory elimination of disturbances than is obtained with the above devices. For short distances between fixed stations, simple unearthed balanced directive aerials in the form of vertical triangles, as used by Bellini & Tosi, give good results. Post Office tests have shown that very powerful long-wave stations may be freely operated at comparatively short distances away without producing the least disturbance on such a system, quite irrespective of directional properties. Musical-note transmission reduces interference, but this method has not yet been tried in the Post Office.

The author then deals with atmospheric electrical perturbations which are heard in the telephone receiver as a series of scraping, scratching, and explosive noises. They are more prevalent during the summer than the winter, and are particularly troublesome during thundery weather. Records taken in December, 1910, at the Post Office stations showed that though the disturbances were not precisely of the same character at each place, there is no very marked variation, the periods of maximum and minimum disturbances coinciding. With regard to reducing such interference, tuning does not appear to offer a complete solution, as the disturbing influences have no specific wave-length of their own, but seem to be the result of sudden changes in the electrical state of the atmosphere, which set the aerial oscillating at its own frequency. Heavy damping of such oscillations, such as by the use of a long, light aerial for receiving only, is a possible solution to the problem.

Finally, the author gives a few notes upon "freak" communications due to changes in the transmitting efficiency of the atmosphere. These are more pronounced at night, but do not synchronise with the periods of atmospheric disturbances. They hardly affect the working of coast stations with ranges up to 200 miles.

DISCUSSION IN LONDON.

Commander F. G. Loring (Inspector of Wireless Telegraphs, G.P.O.) said that if ships were equipped according to the standard required by their licence, there should be no interference between the 600-metre wave and the 300-metre wave at a range of three miles or more. Further, it should be easily possible to use a wave-length of about 150 metres, and under favourable conditions another of about 450 metres, and these should be obtained with any set of good standard apparatus. In practice, advantage was not generally taken of these facilities, because the apparatus was not always properly installed, and because, generally speaking, the operators were not sufficiently competent. Measurements were taken last week of the wave-lengths of thirteen ships installed with apparatus for 300-metre (984 ft.) and 600-metre (1,968 ft.) wave-lengths, and figures were obtained of 2,020 ft., 1,500 ft., 1,968 ft., 2,220 ft., 1,670 ft., 1,200 ft., 1,000 ft., 1,817 ft., 1,830 ft., and 1,520 ft. It seemed that with such variations no amount of tuning would prevent interference. During recent years, however, there had been a great improvement in ship installations, and the apparatus worked within 5 or 6 per cent. of the 300 or 600 metre wave-lengths, for which they were designed. A musical-note transmission would help operators very considerably, both as regards interference and speed of working. Such a note should preferably be of an aggressive timbre like a brass instrument as opposed to the soft tone of a flute. The multiple tuner was used a great deal at shore stations, but the percentage of ship operators who used it was very small. He had collected notes on atmospherics for several years, reports being sent in every month. The worst months were October, June, and July, and the best January, February, and March; the worst hours were between sunset and sunrise, and the freest period was between sunrise and noon. Other things being equal, short wave-lengths under 2,000 feet were very much less affected by atmospherics than long ones. In the case of two stations, one using a 4,000-feet wave-length, and the other about 2,000 feet, the disturbance from atmospherics on the short one was two hours per day, whilst on the long one it was twenty hours. At Crookhaven it was frequently necessary to suspend communication with ships altogether until the signals improved. All three Irish stations experienced particularly strong atmospheric disturbances with north-west winds. The best "freak" recorded at Hunstanton were signals from a ship 300 miles south-west of Cape Blanco in South Africa, or a total distance of 2,800 miles. Another curious point in connection with "freak" ranges was that North Foreland, Bolt Head, and Crookhaven never intercommunicated, or only extremely rarely, and yet all of them frequently intercommunicated with ships in the Mediterranean at night. These signals were found as strong as those of ships only twenty or thirty miles away. There were three stations on the Morocco coast which seriously interfered with traffic in the Channel at

Hosted by Google

night, and similar interferences were experienced from the American Fleet when it was in the Mediterranean. He was glad to say, however, that it was a rare thing to receive any report of interference with commercial work by the British Navy.

Sir Oliver Lodge said that the operators seemed to be extraordinarily good, to judge from the manner in which they picked out the thing they wanted to attend to in the midst of a perfect babel of other communications. What would happen in war time, when everybody was trying to disturb everybody else, he really did not know. He asked Commander Loring whether there would be any objection to a lower capacity aerial on a ship. He supposed it was the universal custom for the lower aerial of ship installations to be the earth, or rather the sea. With land installations, when using the earth as the lower capacity, it had been found that the tuning was spoilt. After a long series of experiments Dr. Muirhead had designed an aerial in the form of a Maltese cross suspended horizontally, the aerial wire being connected to the centre. He was surprised that this gave such good results, and it appeared that the reason was as follows: The surges rushed up the aerial wire, divided, and all reached the points of maximum potential at the same time, then surged back and travelled down the aerial wire also together, instead of going down in a procession as they did when the aerial was not symmetrical and the different paths of unequal length. The resistance of the earth was the trouble, and whether this was overcome in the case of the sea, where there was salt water, he did not know, but from the Paper it did not appear that everything was right. The lower-capacity aerial had got over the trouble on land, and he thought that it would on sea, unless there were practical objections from the nautical point of view. As regards tuning out, the Admiralty, who, he believed, had a system of their own, were unable to tune out an adjacent Lodge-Muirhead station, whereas the latter station was easily able to tune out the Admiralty station. As regards Mr. Taylor's remarks as to "precharged" aerials, he did not deny that his system did perturb other installations, but the electrostatic effect could only do so if the collector were untuned. With his system he had given tuning one of the severest tests—namely, to have two stations in a field, one speaking to a distance and the other receiving and tuning out all interference from the speaking station. Further, by means of the Maltese cross arrangement he could split the aerial into two, and receive two different sets of signals at the same time.

Mr. W. Duddell thought they were all working on wrong lines in trying to reduce the power required to a minimum. He suggested that ten times the power at present used should be employed. He had always had a great doubt as to the theoretical advantage of the multiple circuit in the Marconi multiple tuner, and suggested that the advantage gained was due to the very loose coupling only. With regard to atmospherics, he asked whether these propagated themselves with the speed of light, and whether it is possible to determine the difference of time between the arrival of atmospheric disturbances at two different points, say, 1,000 miles apart. Such experiments might give an indication of the direction from which the disturbances came. Upon the point that long waves were affected more than short ones, did this apply to stations with short aerials adjusted for long waves as well as stations with large aerials, because the latter, owing to their size, were very liable to pick up atmospheric disturbances? On the question of precharged aerials affecting the ordinary coupled receiving stations, he agreed with Sir Oliver Lodge that the electrostatic action could not really be an explanation, because the effect was observed over a mile or two. He thought perhaps the effect was due to the shape of the wave train. Thus, the wave train from the Lodge precharged aerial consisted of a series of oscillations beginning with a wave of large amplitude and gradually diminishing, while the wave train from a coupled aerial started with a wave of small amplitude which gradually increased by resonance to a maximum, and then diminished again. The maximum in the latter case was not so great as the amplitude in the first wave from the Lodge aerial, which was sufficiently large to set the receiving circuit of a coupled aerial in oscillation by shock excitation, especially as receivers were usually tightly coupled in order to get sufficient energy. On the other hand, it appeared that a receiver coupled to a Lodge aerial was not excited in this way by the waves from a coupled transmitting aerial.

Sir Oliver Lodge thought Mr. Duddell had probably given the right explanation. The power used by the Lodge-Muirhead system for signalling between Burmah and the Andaman Islands, a distance of 300 miles, was less than ½ h.p. He hardly agreed with Mr. Duddell as to the need for greater power: he preferred to see accurate tuning and small power. He had heard no complaints of interference from the Burmah-Andaman installation.

Dr. Erskine Murray disagreed with Mr. Duddell's idea of the shape of the wave-train from a coupled transmitter. The aerial was charged up to maximum potential before the spark occurred by transformer action at the low frequency of the charging circuit, and there was a sudden fall in potential when the oscillations commenced giving an impulse of large amplitude before the resonance train took place. With regard to selectivity with continuous-wave systems, if everybody worked with the pure sine waves of the simple Duddell arc, then extremely good results in tuning could be obtained, but the trouble was to get enough energy with such waves. It was necessary to force the arc in some way by a transverse magnetic field, and certain proportions in the capacity and inductance in the oscillating circuit. If they could get a sine wave they would get something, not, perhaps, a great deal better than a good spark system, but certainly better than the ordinary average continuous-wave system. He believed it was a fact that directive aerials suffered less from atmospherics, probably because one class of atmospherics comes from all directions, and, therefore, the directive aerial picked up less than a non-directive aerial. There was not the slightest doubt that a large number were shock disturbances due to sudden discharges at a distance, such as thunderstorms in North Africa and elsewhere.

Mr. A. S. M. Sörensen pointed out that Mr. Taylor had advocated, for minimising interferences, the use of loosely coupled, slightly damped receivers, and that for continuous-wave systems, such as the Poulsen system, a receiver of this kind was not only desirable, but necessary. Among the points in favour of the Poulsen transmitter were the comparative smallness of amplitude and the continuity of the waves and the sharpness of tune. With regard to the use of the term "undamped," it was true that a single oscillation from a Poulsen transmitter could not be presented by a pure sine-curve, but whereas the discharge of a spark oscillator caused a train of oscillations with a constantly decreasing amplitude, the arc oscillator gave a train of continuous and uniform oscillations. As damping generally referred to the proportion between the amplitudes of consecutive oscillations, the term "undamped" did not seem altogether out of place, as applied to the Poulsen system. As the signalling was effected by a small variation in wave-length, only very sharply tuned receivers could intercept the signals.

The author said a few words in reply, reserving his full reply for the *Journal*.

DISCUSSION AT NEWCASTLE.

Prof. H. Stroud believed that with the musical spark messages could be received even when atmospherics were fairly large.

Mr. A. S. M. Sörensen said that he had never heard of his station (the Poulsen Station at Cullercoats) causing the slightest inconvenience to any other station.

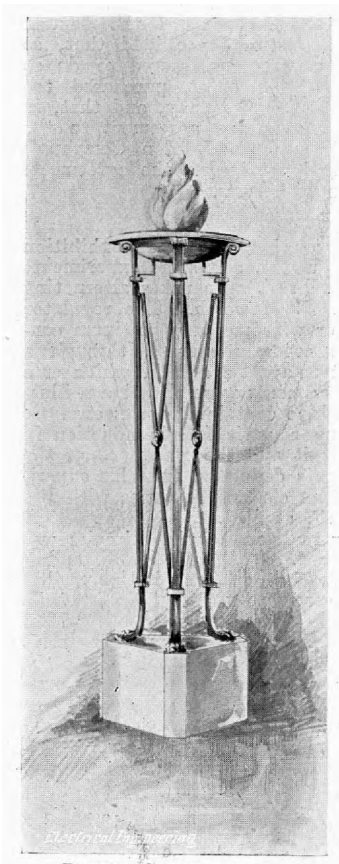
Mr. H. Morris-Airey said that it was possible to ascertain at Armstrong College that the Cullercoats Station was sending, only by tuning very carefully to their particular wave-length, in spite of the fact that they were only 8¾ miles away. In conjunction with Dr. Eccles he made a special study of atmospherics last summer by means of stations at Newcastle and London. The disturbances were carefully timed at each station, and the character noted. The results were similar at each station, and he concluded that the disturbances were not local, but were due to discharges taking place at a great distance from both stations—probably in the upper parts of the earth's atmosphere. He thought that it would eventually be proved that there was some connection between these disturbances and sun-spots. The disturbances detected depended upon the wave-length to which the receiving circuit was tuned.

Mr. J. B. Johnson described how the Cullercoats Station affected the working of the telephone line run into it. It was eventually found necessary to run a lead-covered twin cable right up to the station instrument from a point outside the influence of the aerial.

Mr. J. M. Robb said that telephones were liable to disturbances due to precharged aerials in the shape of telegraph wires, and considerable care was necessary in order to shut these out. He asked if unexplained failures of telephone lightning arresters might not be due to wireless telegraphy stations in the vicinity.

Mr. A. Patterson mentioned some early experiences with the system of wireless telegraphy in which parallel wires are used. This was thrown out of action, sometimes for weeks, by atmospherics, and it was found that a current of 2 to 3 milliamperes was generated in the receiving wire, the direction depending upon whether the tide was ebbing or flowing.

Mr. C. Vernier thought that the Poulsen system had many advantages over the spark system, especially as it was less likely to interfere with other stations. He suggested that atmospherics might be due to lightning storms in the tropics.



Mr. J. E. Taylor (in reply) said that in reference to the question which had been raised regarding the musical spark, he preferred a good scratchy note as being easier to detect. The fact that different disturbances were detected on differently tuned receivers simply showed that the disturbances had sometimes a wave-length of their own. He did not think that local weather conditions had anything to do with disturbances. Telephone lightning arresters, to be affected at all, would have to be in the field of the aerial. There was undoubtedly some connection between atmospherics and magnetic storms. The Poulsen system was useful for certain purposes, but not for isolated stations, on account of the amount of power required. There could hardly be a connection between tropical storms and atmospherics, as the latter have a diurnal variation, while there is no reason to believe that the former have.

THE ELECTRICAL INSTALLATION AT THE ROYAL AUTOMOBILE CLUB

THE new building for the Royal Automobile Club, occupying a portion of the site of the old War Office in Pall Mall, which, after having been about two years under construction, was opened on March 23rd, is one of the largest and most luxuriously fitted club-houses in the world. We will not attempt here to give a general description of the many unique features of the building itself, as these have been fully dealt with in our non-technical contemporaries. The electrical installation, however, is worthy of detailed attention. It was carried out by Messrs. Higgins & Griffiths (21, Orchard Street, Portman Square, W.) to the specifications of the consulting electrical engineer, Mr. E. Wingfield Bowles; and the chief feature of the lighting installation, apart from its magnitude, is the way in which no effort has been spared to obtain the best effects both artistically and from the point of view of illumination. The power equipment has several features of importance, while the fire-alarm installation is of particular interest.

In order to reduce to a minimum the possibility of a total extinction of the lamps, the lighting circuits are supplied from two separate services from the St. James' and Pall Mall Electric Light Co.'s system. One service is from the street mains, and the other is taken direct from a sub-station supplied straight from the Grove Road, St. John's Wood, generating station of the Central Electric Supply Co., from whom the St. James' Co. obtain a portion of their energy. The supply in each case is D.C. three-wire, with 220 volts across the outers. The concentric services are brought to dividing boxes in intake rooms below the switchboard rooms, and the cables are then run up through main fuses to two main boards, one for each supply. The lighting points in every room of the building are as nearly as possible equally divided between the two supplies, so that should one fail, the whole of the building will still be lighted. In small bedrooms, for example, the pendant is off one supply and the plug fitting off the other, while in the larger rooms alternate fittings are wired off the second supply. The two boards are thus duplicates of each other, except that one controls, in addition, the power circuits, and the other the pilot lighting of the corridors, &c., in connection with the fire alarm installation. The main lighting boards each comprise between 20 and 30 sub-circuits of about 100-ampere capacity, each balanced across the two sides of the system; each circuit has double-pole switches and cartridge fuses of the porcelain holder pattern mounted on marble panels. The main cables are paper-insulated, lead-covered, and the sub-mains are paper-insulated, lead-covered, and armoured, with the sealing boxes bolted to the steel framework of the board. This latter is earthed to the fire water main by means of a 19/14 cable in a special conduit, so that efficient earthing of the armouring of the cables is ensured. The wiring from the sub-boards is carried out in heavy-gauge E.S.C. welded screwed steel conduit, and the steel cases of the sub-boards to which the conduit is connected are all earthed by 7/16 cable to the nearest water-pipe, also in a special conduit. The distribution boards are lined with Uralite, and have glazed wood fronts. They are divided into two portions, one above the other, containing the tubular fuses and the tumbler switches respectively. While the attendants have keys for the switch portions, only the electrician has the key of the fuse portions. Front connections are employed in all cases. Great care has been taken to keep the conduits of the different supplies entirely separate; the two runs are placed quite apart under the floor, and no switch or fitting on one circuit is within six feet of any switch or fitting on the other circuit. To facilitate installation and repairs, the two sets of circuits are wired with different coloured wires. The switches throughout the building are of the flush type, with the exception of those on the service and fifth floors. Lundberg plugs are used throughout, and where heating circuits are provided a device is employed to prevent the heating plug being inserted in the lighting circuit or *vice versa*. A complete bell installation is provided on each floor, and the electrical contractors also provided the conduits for the telephone system, which includes a private branch exchange with twenty incoming lines, and a very large number of extension instruments, installed by the National Telephone Co.

Bronze Standard for Swimming Bath.

Bronze Pendant for Swimming Bath.

An important feature of the wiring work is that the cables were not drawn in, but were pushed through, inspection boxes being provided at all bends to facilitate this. The tubes were provided at all ends with hexagonal screwed brass bushes, nicely rounded off. On the main boards, in addition to the Supply Co.'s meters (Ferranti type) are twenty sub-meters (Chamberlain & Hookham type), which are used to measure separately the power taken by the different departments, such as the restaurant, for which it is desired to get out separate accounts.

The arrangements for controlling the pilot lighting in connection with the fire-alarm system is exceedingly ingenious. All the points in the corridors, staircases, passages, and entrance hall are controlled by two-way tumbler switches, and the 50-ampere switches controlling these circuits on the main board (ten in all) are triple-pole switches, the mains on one pole being split. One side of the switch supplies the lamps through the ordinary sub-distribution boards and local switches (when in the "on" position) in the usual way, while the other supplies

Hosted by Google

the lamps through special sub-distribution boards and the off-position contacts of the two-way local switches. On this side the supply is normally broken by a single-pole switch held open by a catch. Should a fire-alarm push be operated in any part of the building, and the fire-alarm circuit closed, an electromagnet pulls up the catch and allows the switch to close, thus lighting up all the lamps in the corridors, &c., should the local switches be in the "off" position. It may be mentioned that the fire push-buttons are held open by the glass covering them. On breaking the glass, the button springs out and makes contact. This rings bells and actuates indicators in six places —namely, the rooms of the secretary, engineer, porter, manager, the manager's private room, and the boiler-room. No general alarm is sounded, and a fire can thus be localised and dealt with without creating a panic.

The 220-volt power board controls 15 circuits of from 100- to 150-ampere capacity each. It is fitted with an Elliott recording ammeter. It may here be mentioned that all the switchboards, distributing boards, and switches with the exception of the tumbler switches, were manufactured for Messrs. Higgins & Griffiths by Messrs. E. F. Moy & Co., of Camden Town. The power equipment includes eight Otis lifts (two passenger, one goods, and five service lifts), ventilating plant, pumps, air-compressors, and auxiliary plant in the boiler-room, &c. In all there are 34 motors installed. The ventilating plant by R. Crittall & Co. consists of two 14-h.p. motors driving centrifugal fans, which draw air in from outside through filters and deliver it through ducts into the various rooms, and one 24-h.p. and two 15-h.p. motors driving fans on the roof, which draw the air out through other ducts. The incoming air is warmed in winter and cooled in summer, and so far as one can judge from the short time the club has been open, the ventilation and temperature control is very superior to that in most large buildings.

Two 15-h.p. motors (by Electromotors, Ltd.) drive two Gwynnes centrifugal pumps, which are employed to circulate the water of the swimming-bath. This is continually drawn through filters and pumped up to the top of the building, where it is aerated before being returned to the bath. Another pump (13 h.p.) is installed in connection with the fire arrangements. This is controlled by an automatic starter, which is actuated by a relay controlled by the main fire hydrant supply. Thus should the pressure in this water main fall, the pump is immediately set in operation. As the basement is below the level of the main sewer, it was necessary to provide sewage raising plant. This was installed by Hughes & Lancaster, Ltd., and consists of compressed-air ejectors, which raise the sewage to the required level. There are two compressor pumps, one working intermittently to maintain the required air-pressure, and the other held in reserve. Each has an Adams automatic starter controlled by an air-relay, which starts and stops the motor so as to maintain the air-pressure within certain limits. Berry Skinner ironclad double-pole switches are used in connection with all the motors.

Perhaps the most striking features of the whole installation are to be found in the lighting arrangements. A large variety of elaborate and costly fittings were especially designed to harmonise with the different styles of decoration employed in the various rooms. Thus in the ladies' reception-room and restaurant, which were decorated by a French firm, large special Louis XV. candle electroliers and wall brackets are employed. Special glass fittings are used in the large smoking-room, and harmonise well with the Georgian style of decoration. The accompanying illustrations show the two designs employed for the standards and pendants in the swimming-bath, which has imposing architectural features carried out in the Pompeian style, with columns decorated in coloured mosaic. The fittings illustrated are of solid bronze, and are exact replicas of fittings which were found in Pompeii, and which date back about 2,000 years. A feature of these fittings is that Messrs. Higgins & Griffiths have succeeded by a special process in reproducing very faithfully the green colouring of the old bronze. The swimming-bath is also provided with concealed lighting by rows of lamps in the cornice, and the effect produced is to bathe the whole place with a powerful but diffused glow, while the unpleasant contrast between the bright ceiling and the unlighted walls so often seen in examples of indirect lighting is avoided by the presence of the ordinary fittings as well. It is important to notice, however, that these are so constructed that the lamps are shielded from the eyes of those in the water. The lighting of the large hall, known as the Great Gallery, is also worthy of especial mention. This has three massive 30-light candle lamp Louis XIV. pendants, and eight 4-light candle lamp brackets. There are besides these 450 20-watt lamps in the cornice, which illuminate a fine painted ceiling. They also provide a very soft general lighting, any monotony of which is removed by the candle fittings. It is impossible to particularise the styles of fitting employed all over so large a building; the needs of each situation have been studied independently. The billiard-table lighting is a special feature, and most handsome cut-glass bowls are used in the committee-room, libraries, &c., as well as in the first floor corridors and galleries in combination with massive wall brackets, and extensive use is made of holophane spheres in the upper corridors, offices, and other situations. All the lamps in the building, with the exception of some of the candle-lamps, are Ediswan metal filament. The lighting of the squash racket courts also deserves mention. In each are suspended three "Tantalite" battens similar to those employed for stage lighting, each containing twenty-four 20-watt metal filament lamps.

In conclusion, we should like to express our indebtedness to Mr. J. W. Orde, Secretary of the Royal Automobile Club, for giving us permission to inspect the installation; to Messrs. Higgins & Griffiths, the sole contractors for the electrical installation, for preparing drawings of the swimming-bath fittings especially for us; and to Mr. H. T. Hocking, their representative, who has been in charge of the installation work from the beginning, and who kindly conducted our representative over the building.

DISPUTE BETWEEN LONDON ELECTRIC SUPPLY COMPANIES

MR. JUSTICE JOYCE gave judgment on Saturday in the action by the London Electric Supply Corporation against the Westminster Supply Corporation for alleged breach of an agreement between the two companies, under which the Westminster Co. have taken over the management of the London Company's Westminster area. The agreement in question has been made under the London Electric Supply Act of 1908. The terms of the agreement include the payment to the London Company of certain annual sums to meet standing charges, and upkeep of the works of the London Company in respect of the Westminster area, and a sum of 0·85d. per unit for all energy supplied to the consumers of the London Company in that area. There are also one or two other small charges to be made by the Westminster Company. The complaint against the Westminster Company was that they were endeavouring to induce the consumers of the London Company in the Westminster area to transfer to the Westminster mains, instead of acting as managers to the undertaking and doing their best to develop it as a portion of the business of the London Company. In his judgment Mr. Justice Joyce held that, so far as the Westminster Company were empowered to do so under the Act of 1908, they had, in effect, purchased the Westminster undertaking of the London Company, and that, in the absence of any specific clauses in the agreement to the effect that they were not to induce the London Company's consumers to change over, they had not broken the agreement. He therefore dismissed the action with costs.

Physical Society.—At a meeting on March 24th an exhibition was given of a sensitive thermo-regulator, and some experiments on the measurement of electrolytic resistance using alternating currents were shown by Dr. H. F. Haworth. The regulator consisted of a toluene thermometer with mercury platinum contacts in a capillary tube; these contacts operate, through a Siemens telegraph relay, an electromagnetic switch, which cuts in or out the heating circuit. Experiments were also shown illustrating the ease with which a bridge containing an electrolytic cell could be balanced by placing a variable self-induction in series with the cell and adjusting it and the resistance of the bridge simultaneously. The author's deduction from his experiments was that the resistance of an electrolyte varies with the frequency of the alternating E.M.F. applied.

A Paper on the oscillatory currents in coupled circuits was read at the same meeting by Prof. G. W. O. Howe, and a demonstration was given by means of a double projection oscillograph of the currents in coupled oscillatory circuits. Each circuit consisted of a condenser, an air-core choking oil, and a strip of the oscillograph. The condenser in the primary circuit was charged and discharged by means of a commutator on the spindle of the oscillograph motor, and every change in the currents in the two circuits due to a variation in the damping of either circuit or in the coupling between the two circuits could be followed. A third oscillatory circuit represented a wavemeter, and could be used to plot resonance curves, from which the damping could be calculated. By altering the connections the conditions of the quenched spark-sending apparatus was represented. Some radio-telegraphic apparatus in use at the City and Guilds College was also exhibited by Prof. G. W. O. Howe. The receiving apparatus was shown connected up to the aerial, which is 260 feet high, and a transformer specially designed for experimental work at long wave-lengths was shown. By means of a Brown telephone relay and special trumpets fitted to the telephone receiver, the time signals and messages sent out from Norddeich and from the Eiffel Tower can be plainly heard anywhere in the lecture theatre.

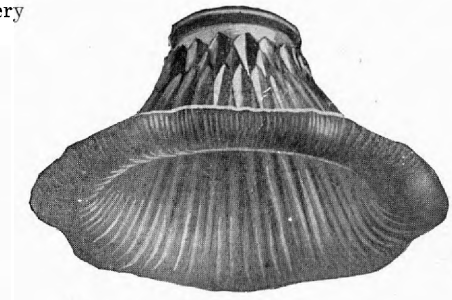
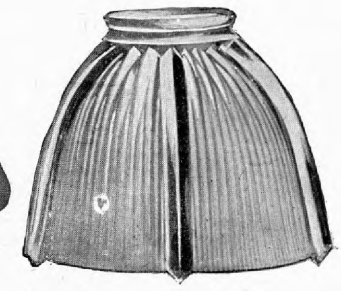
NEW ELECTRICAL SUPPLIES AND ACCESSORIES

Fittings and Accessories.

An attractive list has recently been issued by the British Thomson-Houston Co., Ltd., entitled "Mazda-Holophane Glassware," which illustrates a number of applications of these well-known scientifically constructed shades and reflectors. It is important, to get the best effect out of the combination, that the source of light and the glassware should be in correct relative positions, and the Company have arranged that the position of the filaments in all Mazda lamps conforms with this requirement when a suitable gallery is used. They have themselves brought out a special gallery



Special Spring Gallery for Holophane Shades (British Thomson-Houston Co.) and Mazda-Holophane Chain Pendant.



for the purpose, which is a great improvement over some types in use in that it contains no screws or other loose parts, but keeps the shade in position by a special arrangement of springs, as shown in the illustration. It is also of remarkably good appearance, especially in regard to the way the lamp-holder is hidden. The second illustration shows its application to a pendant, in which the weight of the lamp and shade is borne by a chain, and thus taken off the flexible leads. A number of special fittings are listed for the recently introduced stiletto holophane shades, and other patterns, such as spheres, bowls, &c., which, with metal filament lamps, produce an excellent effect.

We have received particulars during the past few weeks of several novelties in connection with holophane glassware from Siemens Bros. Dynamo Works, Ltd. (Incandescent Lamp and Fittings Department, Tyssen Street, Dalston, N.E.). One of these is the "Samson" holophane suspension, illustrated here, which they are placing on the market for "Stiletto" holophane reflectors. This is specially adapted to tantalum or one-watt lamps, and forms an efficient and at the same time artistic fitting. It is substantially designed, so that the maximum degree of strength is obtained, as, owing to the weight of the glassware, all suspensions should be thoroughly reliable. The "Samson" suspension is supplied either with the ordinary type of ceiling plate and hook for direct connection, or with ceiling plate and hook to cover conduit boxes or ceiling roses, and can therefore be adapted to any existing electric-light installation.

We also illustrate a few out of a series of fourteen new patterns of holophane reflectors, specially designed for household use, which are contained in a new list issued by the firm. These reflectors, we are given to understand, have been specially designed to combine artistic effect with the already well-known scientific properties of holophane glassware. Whilst the ordinary types of "Stiletto" holophane reflectors, which are noted for their exceptional efficiency, are of neat appearance, it has been suggested on many occasions that they were not sufficiently artistic to be used in conjunction with electric light fittings of elaborate design. The "Household" holophane reflectors, however, are made in a variety of shapes, suitable for various styles of electric light fittings. These reflectors are satin finished inside, whilst the outer surface is of clear glass. The prices vary from 2s. 4d. to 4s. 10d. each, according to the design selected. Some of the types are specially suitable for wall brackets, having an arrangement of prisms which strengthens the reflection of light in an outward direction, but which screens a certain amount of light from the wall surface. Other patterns are

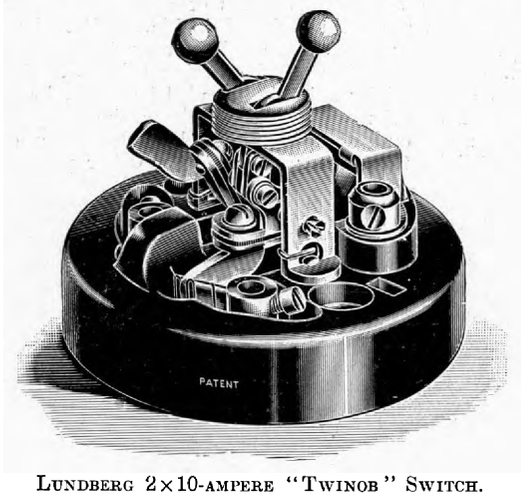
Shade with Satin Finish Inside and Four Clear Ribs.

"Samson" Suspension for Stiletto Holophane Reflectors.

With or Without Satin Finish on Lower Prismatic Surface.

Satin Finish Inside.

New Forms of Holophane Glassware. (Siemens Brothers Dynamo Works.)



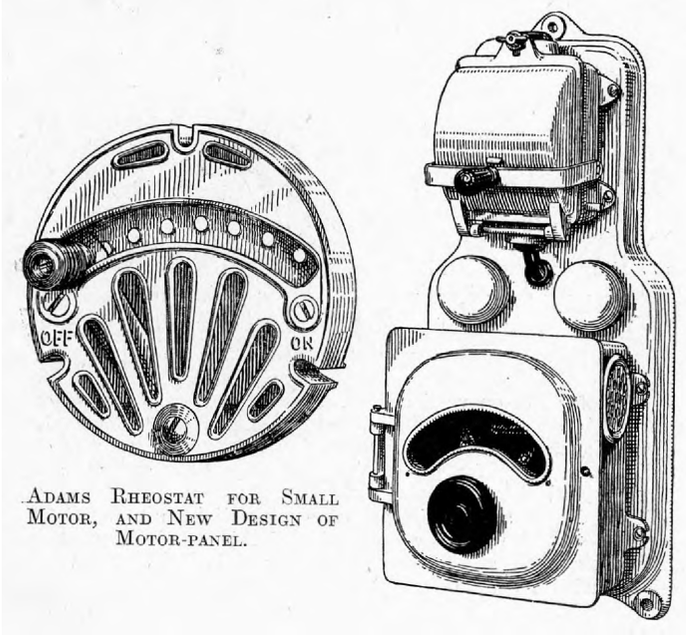
suitable for use on vertical lamps, such as table standards or upright bracket lamps. This is particularly suitable for table decorations, &c. The list in question mentions a number of galleries suitable for use with these reflectors, and we are convinced that the "Household" type of holophane reflector will appeal to a wide section of electric light users. Contractors should write for quantities of this list, over-printed with their name and address, as it is anticipated that a very large business will be done in this type of glassware.

Switchgear.

Messrs. A. P. Lundberg (477–487 Liverpool Road, Islington) have just introduced a larger size of their well-known "Twinob" switch, which should prove a very useful piece of apparatus. The new switch, which is illustrated here, has a capacity of 10 amperes per way, and the switch movements and arrangement of parts on the base are somewhat different from those in the smaller type. Knife contacts are now employed at both ends of the contact arms, so that a wide double break is obtained without excessive width, and mica is used for the insulation of current-carrying from other parts.

Hosted by Google

The switch should find extensive adoption for cooking and heating apparatus, as variations in the degree of heat can be very simply arranged when the knobs are actuated separately, full heat being obtained when both are in their "on" positions together. By coupling the two levers together an efficient switch of 20 amperes capacity on a base 3¼ in.



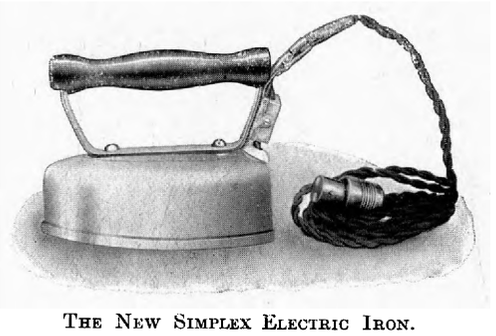
Lundberg 2×10-ampere "Twinob" Switch.

diameter is then produced, with subdivided double break, particularly as the circuit is broken in four places. In this application the supply wire to the apparatus controlled might need to be divided between two terminals, as a bridging strap cannot be conveniently fitted.

By coupling the levers in this way, and dividing the "common" strap which ordinarily connects the back contact-clips, a satisfactory double-pole switch of 10 amperes capacity is produced. In this case fibre-lined metal covers or porcelain covers would be supplied.

Again, by making one of the contact arms spring-controlled —*i.e.*, flying back into its "off" position immediately pressure on the knob is removed, the switch then forms a suitable pattern of starting switch for some types of small A.C. induction motors.

A simple and compact form of rheostat of substantial design for the speed regulation of small motors and similar purposes, which can also be used as a field regulator for



Adams Rheostat for Small Motor, and New Design of Motor-panel.

generators of small size, or as a dimmer for lighting circuits, has recently been introduced by the Adams Manufacturing Co. (London and Bedford). The apparatus, as can be seen from the illustration, is of the semi-enclosed pattern, with the contacts visible, but impossible to be touched accidentally. The resistance is dust-proof and moisture-proof, and the whole apparatus, which is quite self-contained, weighs only about 2½ lb. The porcelain former has embedded in it the resistance windings and the current-carrying contacts, and the lever is mounted directly on the casting forming the housing. There are thus two easily separable contacts, Six contacts are provided, one of which may be an "off" position.

Another novelty of the Adams Manufacturing Co. is the "Igranic" universal motor panel, also illustrated here, which is particularly intended for small industrial applications of electric drive where low cost is a consideration. The panel embodies many of the features of the larger panels made by the Company, and, besides being easily fixed and wired, is very compact.

Heating and Cooking Apparatus.

Messrs. Simplex Conduits, Ltd. (116 Charing Cross Road), are putting on the market the new pattern of electric iron illustrated here at very reasonable prices, in three sizes, from 3 to 7 lb. in weight. The heating elements are carried on mica and inserted in holes actually drilled in the iron casting, and are therefore entirely surrounded. The heating effect is

The New Simplex Electric Iron.

thus produced as rapidly as possible, whilst the iron maintains a considerable temperature some time after the current has been switched off. The original sample of this iron, made up in the Company's Birmingham works last October, where the apparatus is manufactured throughout, has been on circuit continuously ever since, and has not yet broken down. Heavier weights of the irons suitable for laundry work will shortly be introduced.

The Iron and Steel Institute.—The annual meeting is to be held on May 11th and 12th in London at the Institution of Civil Engineers. The annual dinner will be held on the first day at the Connaught Rooms, Great Queen Street, W.C., under the presidency of the Duke of Devonshire. Some seventeen Papers are down for discussion, among which is one on "Magnetic Properties of Some Nickel Steels, with Some Notes on the Structures of Meteoric Iron," by Dr. E. Colver Glauert and Dr. S. Hilpert, of Berlin. Dr. J. N. Friend and Mr. J. H. Brown (Darlington) will also read a Paper on "The Action of Aqueous Solutions of Single and Mixed Electrolytes on Iron." The autumn meeting will this year, by kind invitation of the Associazione fra gli Industriali Metallurgici Italiani, be held at Turin, commencing on October 2nd, and with the subsequent tour organised in connection therewith will occupy about fifteen days from the time of leaving London to the return. Several other Italian towns will be visited.

Crystal Palace School of Practical Engineering.—The annual award of certificates and the inspection of the various departments of the school were held yesterday. The Right Hon. Sir George Reid, K.C.M.G. (High Commissioner for Australia), was in the chair.

The Fire at Albany, U.S.A.—In view of the rumours that the fire at the New York State Capitol at Albany was due to the "fusing of an electric wire," Mr. H. B. Renwick, chairman of the Electric Supply Publicity Committee, has been in communication with authoritative sources of information in America, and learns that there is no evidence whatever to the above effect, and that the cause of the fire is quite unknown.

"The Generators."—The five hours' full-load run of the 66 generators, on the Caledonian Room Site of the Holborn Restaurant, was successfully completed, without any serious breakdown, on Friday evening last. Chief-generator Harrison, with the assistance of automatic-regulator Corneille, switched in the exciting coils common to all the generators. There was a certain amount of irregularity in the switching-in process, due to the chief-generator getting out of step occasionally. Otherwise, the excitation was up to standard, and no hot bearings were recorded. The next full-load run will not take place before the autumn.

PREVENTION OF INTERFERENCE IN WIRELESS TELEGRAPH WORKING

By C. C. F. Monckton

THE Paper read last week before the Institution of Electrical Engineers by Mr. J. E. Taylor shows the small amount of definite knowledge as to the best means of preventing interference to the receiving of wireless signals. It is a question of some difficulty to compare different methods of avoiding interference, say, from atmospherics. Suppose signals are being received at a station B on the magnetic detector from a station A using a loosely coupled Marconi transmitter. Then suppose the three operations advocated by Mr. Taylor are adopted—to reduce the coupling and detune in the best possible manner; again, that a second circuit is fitted on the most suitable differential system; and, further, that the two arrangements are such that the signals come in with exactly the same strengths; then by switching over from one circuit to the other alternate minutes, at a time when atmospherics were abundant, a proper comparison could be made; but it has to be remembered that this comparison would only hold for a magnetic detector under the exact conditions of working. Even with precharged aerials I have noticed that receiving arrangements require considerable modification to obtain the best results under slightly different arrangements of sending.

It is a surprise to hear that Mr. Taylor expects to obtain as good results by detuning as by differential methods. In Trinidad the first operation of reducing the coupling as far as possible is carried out, and then a converse of the third operation—that is, a greater difference between the damping of the aerial and secondary circuit is made by decreasing the

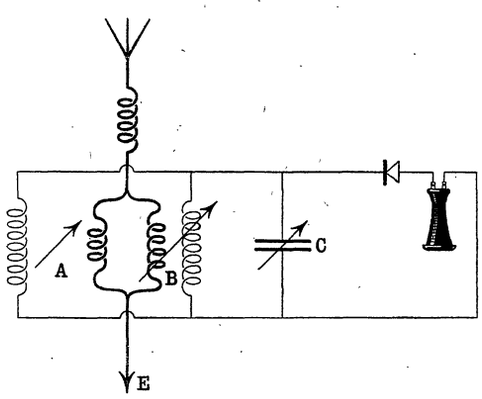

Diagram of Connections.

resistance and inductance of the secondary, keeping it still in tune with the aerial. Often when this has been done the signals come in as strong, or sometimes even stronger, than before, but in other cases the distance between the coils has to be reduced. It is to be noted in carrying out the second operation here described that the coupling is reduced at the same time as the damping of the secondary.

About a month ago, whilst in the West Indies, an operator, Mr. Barratt, informed me that he had been able to reduce atmospherics, and at the same time increase the strength of the signals. I found that he had made use of two receiving transformers in parallel with secondaries joined to the same condenser, as shown in the figure. One of these, A, was loosely coupled, whilst the other, B, was tightly coupled. As this arrangement is very simple, it is to be hoped that it will be tested independently. The writer tried the simple test of using two secondaries with a single primary to show the differential action. When both secondaries were equally coupled to the primary, no signals could be received. The loudness of the incoming signals depended on the difference of the coupling. As the capacity, C, had to be nearly doubled, using two equal secondaries each of the same inductance to that usually employed, the effect might have been due solely to decreased damping, so Mr. Barratt carried out a trial for the writer, comparing the use of one primary with two. To get the desired effect it required two secondaries. The inductance of both the primary and two secondary windings was probably not the same.

There is a curious difference between the Government stations at Trinidad and Tobago, about sixty miles apart. During the summer months there is a thunderstorm in the vicinity of the Trinidad station every few days, but at Tobago there is only about one storm a year. Now at Tobago the atmospherics are much worse; they are especially bad during, and for some time after, the Trinidad storms. I can only attribute this to the earth being better at Tobago. On the other hand, both stations appear to be able to pick up signals from the American stations 1,500 to 2,000 miles away with the same ease. It might be mentioned that most of these stations have waves with two maxima, the wave-lengths of which are about 200 metres apart. The signals from Washington and from a number of the United States battleships come in with a single maximum and a very shrill note. The operators call them "whistling spark" stations. They also find these stations especially easy to read during atmospherics, as the difference of note from the noise of the atmospherics is very great.

I agree with Mr. Taylor that the atmospherics are probably due to the release of charges in the aerial, for the charges required would be so small, the pressures which would cause them are so enormous, and the atmospheric vibrations are always in tune. I have on several occasions used atmospherics to calibrate an aerial. Using a known inductance as the secondary of a receiving transformer and a calibrated adjustable condenser, the secondary can be set at any given wave-length, and the inductance in the primary adjusted till the sound of the atmospherics is a maximum. Calibrating an aerial from about 400 to 3,000 metres by this method, there was no apparent alteration in the maximum sounds received.

In the opinion of the writer, the probable line of progress will be (1) in sending with a high-pitched "whistling spark," whose spectrum has only one wave of maximum power; and (2) in receiving with either a loosely coupled or differential arrangement, but that also the telephone or a relay will be used so made as mechanically to be in tune with the spark frequency of the sender whose signals it is required to pick up, also that this telephone or relay will be placed in a circuit whose natural period of vibration is that of the spark frequency of the transmitter.

THE LODGE WIRELESS PATENT

THE hearing before Mr. Justice Parker of the petition of the Lodge-Muirhead Wireless Syndicate for an extension of the term of the Lodge patent No. 11,575 of 1897 was concluded on Wednesday of last week, Mr. Justice Parker reserving his decision until after the Easter Vacation. Particulars of the patent and a report of the first day's hearing were given on page 176 of our last issue.

Sir Oliver Lodge, examined by Mr. Walter, explained that the well-known syntonic jar experiment, in which two Leyden jars were tuned so that one would respond by resonance to electrical oscillations taking place in the other, and which he showed in the Hertz lecture in 1894, depended for its effect upon the magnetic induction between the two circuits. He did not then associate this experiment with wave telegraphy. The 1897 patent in question, however, was the application of this principle to wave telegraphy. Inserting an inductance in the aerial would, he then knew, lengthen the wave and reduce considerably the range of transmission, but he realised that this was worth while in consequence of the possibilities of selective working. Further, he realised also that it was necessary to take the detector out of the main receiving circuit and put it in a derived circuit in order that the former might commence to oscillate with feeble impulses and build up a strong oscillation by resonance. Until this was done there was no real tuning; Hertz himself admitted ultimately that he had never had real tuning between transmitter and receiver. Sir Oliver Lodge was then cross-examined by the Solicitor-General with regard to the Parkstone Quay wireless station of the Great Eastern Railway Co., which employed the Lodge-Muirhead system. They were there able to tune out the signals from the powerful Admiralty station at Felixstowe, which was in sight of the other station, and receive weaker signals tuned to their own apparatus.

Dr. Silvanus P. Thompson, examined by Mr. Walter in support of the petitioners, interpreted the nature of the patent, and stated that in his opinion the invention was a most important one, and had not been anticipated.

Mr. H. Muirhead, a director of the Lodge-Muirhead syndicate, stated that the family of Muirhead was about £20,000 out of pocket in respect of the invention, and referred to the success of the Andaman Islands installation, which gave a range of over 300 miles with a plant of only one-half horse-power. Cross-examined by the Solicitor-General, he said that the Admiralty had suggested that they should take proceedings against Marconi.

Mr. C. F. Wilkins, of Muirhead & Co., Ltd., questioned by the Solicitor-General, stated that complaints had been made at one time of the interference by the Parkstone Quay, Lodge-Muirhead station with the Felixstowe station, which was, he believed, a Marconi installation. No complaints were now made, however.

The Solicitor-General, speaking on behalf of the Crown, pointed

Hosted by Google

out how rarely extensions of patents were granted. The use of an inductance coil in the aerial circuit was common to many systems, yet no steps had been taken by the petitioners to protect their rights, and this was a serious objection to extending the patent. If an arbitrator were called in to settle the terms of licence, he would have to assume that the patent was valid. Sympathy for the petitioners because they had suffered from the refusal of a wireless licence under the Act of 1904 was not a ground for extending the patent.

Mr. Gray then spoke on behalf of the petitioners, emphasising the fact that other companies, including the Marconi Co., had had an opportunity to object, but had not chosen to do so. If the patent were extended, the petitioners would undertake not to take proceedings against any existing installation for infringement, nor attempt to obtain damages for past infringement. Further, they would grant anyone a licence to employ the invention on reasonable terms which could be settled by the Board of Trade or a suitable expert body. Mr. Gray also suggested that the Lodge-Muirhead Syndicate would make use of their rights under this patent to bring a counter-action against the Marconi Co., if the latter attacked them on the 7,777/04 patent.

Mr. Justice Parker here mentioned that he was of the opinion that Sir Oliver Lodge had not got what he deserved, and that he was anxious to help the company. On the other hand, he would not grant an extension if it was part of a plan to make money out of the Marconi Co. or the Government by attacking them for infringement, and not by legitimate trading under the protection afforded by the patent. On Mr. Walter's construction of the patent, it covered an essential part of the four-circuit system used by Marconi, but he was not satisfied that the patent so construed was valid.

Mr. Gray argued that the Marconi Co. ought to be able to look after itself, and Mr. Walter pointed out that under the Patents Act the Lodge-Muirhead Syndicate possessed rights for six years after the expiry of the patent, even if it were not extended, of suing for damages all infringers during the 14 years of its life. In answer to a suggestion by his Lordship that they might have enforced their rights before making this petition for extension, Mr. Walter stated it was their shortness of means which had prevented such litigation. The patent expired on May 10th, but under the new Act his Lordship's decision could be deferred until six months after that date if desired. Finally, Mr. Walter said that they would try to devise some way of settling the difficulty as regards the conditions under which a grant of extension might be given, and any proposal would be submitted to the Crown and his Lordship.

The Solicitor-General said that he was instructed by the Board of Trade to say that there would be difficulties in the way of its acting as arbitrator. This concluded the hearing.

A NEW FAULT LOCALISER

A COMPACT instrument for fault localising has just been put on the market by R. W. Paul (33 Leicester Square, W.C.). The apparatus is illustrated here, and has several points of interest. It is intended for use principally for carrying out tests by the Murray loop method, in which a balance is obtained on a slide wire, and the ratio of the distance of the fault to that of the whole cable under test is read direct. One important difference between this apparatus and some others is the much greater length of the slide wire, which is wound on a screw-threaded, insulated metal drum, enamelled and further covered with varnished cloth. The slider is brought over any turn, where it is retained by a click, and parts of a turn are read on the divided head at the end which rotates the drum. The movement of this is limited to one turn, and as the drum is mounted on a screw thread, the wire is always accurately under the contact. The disc is divided into 20 parts, there being 50 turns of wire on the drum; the position of the contact may be read to one-tenth of a division, or to one ten-thousandth part of the slide-wire length. The slide wire is connected to the terminals by flexibles without moving contacts. The contact itself can be put into or out of action by an ebonite head, so arranged that undue pressure cannot be put on it, but the actual battery key is separate, so that the slide wire is not exposed to continual tapping. Apart from these constructional points, a special feature is the fact that the distance of the fault can be read direct on the wire without the necessity for correction for the resistance of the connections, as the potential points are taken off the cable itself, and the connections form virtually part of the slide wire, which is graduated, taking this into account. The objection will at once be raised that faults very near the measuring point cannot be exactly determined, and the contact would have to lie beyond the end of the slide wire. An arrangement is provided for putting an additional resistance, nine times that of the wire, in series, to bring the position on to the slide wire. The terminals of the flexible slide-wire leads are arranged to be suitable for almost any kind of cable, and the potential connection is made by wrapping the bare copper braid end of the potential leads round the cable. The potential points are inside the current points, so that the fact in the case of large cables of only a few strands being taken up by the connector does not matter. One of Mr. Paul's well-known "Unipivot"

Fig. 1.—Fault Localising Set. (R. W. Paul.)

galvanometers completes the equipment. A modified form of the apparatus is made, in which a pair of comparison resistances are included in the same box. This can be used as an

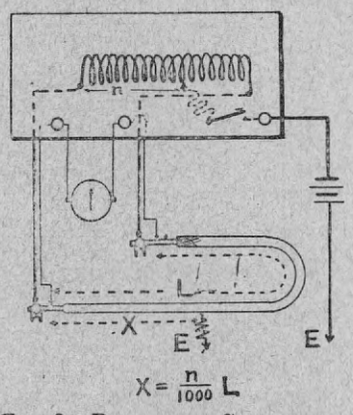

Fig. 2.—Diagram of Connections.

ordinary bridge for resistance measurement, but is not provided with the compensation for the resistance leads when used as a fault localiser

Railless Electric Traction.—Two out of the fifteen Bills which were deposited in Parliament, seeking powers to run trolley omnibuses have been abandoned for the present session. The Bills in question related to Croydon and the Western Valleys of Monmouthshire. The latter has been knocked out by the Standing Orders Committee.

Parliamentary Intelligence.—The Nottinghamshire and Derbyshire Tramways Bill has been passed by the Unopposed Committee of the House of Commons. The Bill authorises agreements between the company and the Nottingham Corporation and the Mansfield & District Electric Traction Co., by which the original scheme of the Notts & Derbyshire Tramways Co. will be carried out. An additional £150,000 capital is to be raised.

The Unopposed Committee of the House of Commons have also passed the Liverpool Overhead Railway Bill, which provides for the rearrangement of the company's capital by substituting debenture stock for the existing debentures, which are repayable in 1913. The Mersey Docks and Harbour Board guarantee 4 per cent. on the new stock.

The Metropolitan Electric Supply (Acton) Bill was read a third time in the House of Commons on Monday.

CORRESPONDENCE

ELECTRIC HEATING.

To the Editor of Electrical Engineering.

Sir,—We notice that Professor Fleming, in his Cantor Lecture at the Royal Society of Arts, recently gave a number of interesting figures as to the efficiency of various methods of electric heating. The results of his tests show, of course, that the immersion form of heater is the most efficient, but we are surprised at the efficiency given in the case of the only one belonging to this class quoted, which is not so high as might be reasonably expected. This was the Therol heater, which,

with a consumption of 300 watts used for 24 hours, enabled 38·4 gallons of water to be raised from 50 degrees Fahr. to 110, giving an efficiency of 92 per cent.

The immersion form of heater is adopted in a modified form for a large proportion of Simplex apparatus; the method of applying the heating element to the utensil is shown in the accompanying sketch. The efficiency obtained would seem to be greater than that found by Professor Fleming.

In a three-pint copper kettle (actual capacity three pints), for example, the quantity of water is raised from 60 degrees Fahr. to boiling point in 14 minutes, with a consumption of 750 watts, giving an efficiency of 97·2 per cent. The construction of the kettle is by no means special, the particular type being of ornamental design in copper for general domestic use, and listed at 21s.

Yours faithfully,
SIMPLEX CONDUITS, LIMITED.

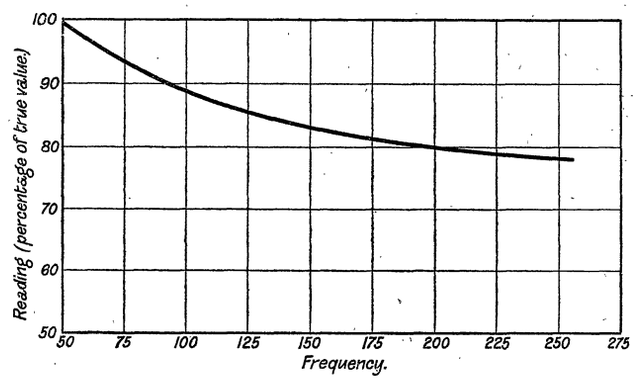
ELECTRICITY METERS.

To the Editor of Electrical Engineering.

Sir,—With reference to the letter from Messrs. Ferranti, Ltd., in your last issue, and especially to the figures they give for the accuracy of commutator meters, it seems rather a pity that they should have had to go abroad in order to get these figures. It is surely rather late in the day when the superior merits of the British makes of this type of meter are getting to be thoroughly understood for such a course to be taken. Moreover, with reference to the curve of the Ferranti mercury motor meter, which was stated to be within 1 per cent. from full to 1/20th load, it was really a pity that it was not mentioned what was the full load capacity of these meters.

For while to mention the accuracy of meters at various percentages of load has an understandable meaning in the case of commutator shunted meters, this is not so in the case of the mercury meters, and, consequently, it is impossible to tell from such figures as to the relative performance of meters on the really low loads, which, according to your correspondents themselves, are now the most important.



British meters of the commutator type are thoroughly reliable for accuracy within Engineering Standards' limits, anywhere from full to 1/20th load, and start on less than 1 per cent. load. Thus, commutator meters are obtainable that are accurate down to 0·05 amps., and will start at less than 0·015 amps., even after long periods of service. If your correspondents are able to produce any mercury motor meter, whether new or old, which will do this, it will, no doubt, interest your readers. The general experience is that mercury motor meters will not start on one lamp after being a month or two in service, whether owing to the mercury becoming dirty or to other causes, is not for us to say.

Queen's Road, Battersea, S.W.
April 7th.

Yours faithfully,
The Electrical Apparatus Co., Ltd.,
R. H. Barbour.

We have also received a communication on the subject from Mr. J. T. Irwin (Central Technical College, South Kensington), in which he considers Messrs. Ratcliff and Moore's statement that shunting reduces temperature errors, but may introduce errors on fluctuating loads, unless the inductances of the shunt and bath circuit are balanced. In considering the effect of a varying load it is necessary to divide the mercury ampere-hour meters into two classes, first where the torque is proportional to the square of the current, and second, where the torque is proportional to the current. In the first case if the ratio of the inductance and resistance in the shunt and bath circuits is unity, the current will divide up according to their resistances, and the torque will be proportional to the square of the current in the mains. If the fluctuations of the current are rapid, the speed of the meter will not have time to change as the current changes, and the meter will have a mean torque proportional if the voltage is assumed constant to the *root mean square* current; but the power taken from the mains is proportional to the mean current, and if the meter has been calibrated with a steady current it will always register fast by an amount which in quite ordinary cases might give an error of 5 to 10 per cent. The provision of a non-inductive shunt would tend, however, to decrease this inaccuracy. In the class of meter where the torque is proportional to the current, the introduction of inductance into either of the circuits will introduce no error as long as the voltage remains constant as the current (mean) in each circuit is determined only by the ratio of resistances, and the torque is proportional to the true power.

Mr. Irwin then deals with the effect of wave form, and shows that if the reading of a meter is made independent of frequency it will also be independent of wave form as long as there is no appreciable change in the permeance of the magnetic circuits. As to that, if only the meter reads correctly at one particular frequency, and if one of the curves is a sine wave, it does not matter how distorted the other is, the meter will still register correctly. That is to say, if the pressure wave form of an alternating-current system is kept a sine wave, then an induction type meter can be used to register the energy on very distorted waves of current. In the cases the authors consider they are dealing with a non-inductive load, and

the shape of the wave is the same for both current and pressure. In practice the meters always read slow, and the higher the value of the harmonic in the resultant wave the slower the meters read. This is undoubtedly due to the fact that they do not register correctly the power given by the higher harmonics. The curve reproduced here was obtained by Mr. Irwin for an induction meter tested on a varying frequency at unity power factor. It shows that a meter which was correct at its normal frequency of 50 was 15 per cent. slow at 150 cycles, and 23 per cent. slow at 250 cycles, and therefore we can tell at once, if we know the composition of any wave, how much the error in reading will be.

For the meter tested by Mr. Irwin the current in the disc due to the current coil was displaced from the flux in the disc due to the pressure coil at normal frequency, by an angle equal to the phase displacement between the current, and pressure in the mains, therefore, at zero power factor it did not turn, but as the frequency increased the phase displacement became larger, until at 200 cycles the phase displacement was eleven degrees, and the flux in the disc was lagging behind the current in the disc.

These results explain why it is that on an inductive load the meter reads more correctly than on unity power factor, because if a large inductance is put in to make the current lag, the inductance has three times the impedance to the third harmonic that it has to the fundamental, and in addition the phase displacement is greater, so the actual power due to the third, fifth, &c., harmonics is very small, and therefore the meter will register nearly correctly. The fact that the flux for the harmonics lags in the disc tends to make the meter read too fast for lagging currents, and so compensates at some particular power factor for the reduction in flux in the disc.

If the current in the meter is leading on the pressure the reverse holds, for not only are the harmonics in the current wave exaggerated, but the meter would not read the total power of these harmonics, even at unity power factor. As the frequency increases the flux in the disc due to the pressure coil lags more and more, and therefore for currents leading their pressure waves by nearly 90°, the torque will be negative, and will oppose the main torque. The effect of this is very evident to distributing engineers, as they very often find that at the sending end of a high tension underground main, where there is a capacity current flowing into the mains, the meter reads *less than* the one at the receiving end by as much as 10 per cent., and this even when the meters have been carefully calibrated beforehand. The conclusion to be drawn is that each type of meter should be tested at frequencies much higher than those at which it has to be used, and rejected if it is not up to a definite standard.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published April 6th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.
Names in italics indicate communicators of inventions from abroad.

19,932/08. **Tungsten Filaments.** A. G. Bloxam (*Siemens & Halske A.-G.*). This patent covers a process of manufacturing a ductile alloy of tungsten with nickel by heating a mixture of tungsten and nickel powders or oxides of these metals, which are afterwards reduced in order to obtain a ductile rod of the alloy. At a certain critical temperature (1510° C. for an alloy of 90 per cent. tungsten and 10 per cent. nickel) the alloy changes, so that when cold it is ductile enough to be rolled and then drawn into filaments. The nickel is volatilised so as to leave a pure tungsten filament by passing a current through the filament in a vacuum.

15,621/10. **Metal Filament Lamps.** F. Skaupy (Berlin). This specification describes the insertion into metal filament lamp bulbs of chemical compounds, which, when heated by the normal working of the lamp, will give off halogen vapours. If the pressure of the gas is so small as to be hardly measurable, its presence is said to diminish the disintegration of the filament and consequent blackening of the bulb.

20,491/10. **Cooling Armatures.** Siemens Bros. Dynamo Works, Ltd. (*Siemens-Schuckertwerke Ges.*). A cooling liquid (water) is passed through longitudinal passages in the core of the armature or rotor, and instead of conducting the liquid through the shaft stationary devices are provided at each end for carrying the liquid into and away from the passages. The passages increase in section towards the outlet end, and the cooling may be further assisted by a current of air drawn through other ducts and passages in the core. Four figures.

23,121/10. **Metal Filament Lamps.** K. Schröter (Berlin). Previous to placing the filament on its carrier, it is wound on a zig-zag former and the parts where it takes a sharp curve round the pins—*i.e.*, where it will engage with the supports—are bent or kinked by means of a heated pair of pliers. The method is particularly suitable for use in connection with delicate carriers which will not stand the tension in stretching the filament round the supports. Three figures.

29,595/10. **Waterproof Motor.** W. R. Macdonald (London). This specification describes a motor for working under water. It is totally enclosed, but clean water is circulated inside, and is supplied by means of pipes from an outside source. A valve is provided whereby the water may be expelled from the casing by compressed air for cleaning. One figure.

4,871/11. **Induction Motors.** H. Maxwell (Schenectady, U.S.A.). To improve the torque of induction motors with squirrel-cage rotor windings, the connections between the rotor conductors and the short-circuiting rings are doubled back upon themselves so as to have an appreciable length and resistance with minimum self-induction. Two figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.
Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: Siemens-Schuckertwerke Ges. [Search-lights] 28,356/10.

Distribution Systems, Cables and Wires, Insulating Materials, &c.: Conner and Peel-Conner Telephone Works [Cable coverings] 13,176/10; Western Electric Co. (*E. Zwietusch & Co.*) [Protective covering for flexible conductors] 24,122/10.

Dynamos, Motors, and Transformers: Kunkel, 29,941/10.

Electric Ignition: Smith and Curtis's & Harvey, Ltd. [Blasting cartridges] 14,905/10; R. Bosch [Drive of magneto apparatus] 24,157/10.

Electrochemistry and Electrometallurgy: Hannemann [Primary cells] 17,336/10; Canning [Electroplating apparatus] 18,695/10; Hesseln [Two-fluid cells] 26,959/10; Pucklitzsch [Electroplating apparatus] 29,473/10.

Incandescent Lamps: Atwood, 23,535/10; Skaupy [Metal filament lamps] 24,549/10.

Instruments and Meters: Jung [Recording apparatus] 6,802/10; Wimperis and Elphinstone [Speed and acceleration indicator] 7,285/10; Dunoyer [Instruments for measuring magnetic fields] 17,624/10; Eversheds & Vignoles, Ltd., and Eversheds [Hand spikes for making connections] 30,313/10.

Switchgear, Fuses, and Fittings: Hope [Fuses] 3,883/10; Field and Ferranti, Ltd. [Circuit-breakers] 6,633/10; Burley and Froude [Table or wall-bracket lamp] 6,905/10; Adams Manufacturing Co. (*Cutler Hammer Mfg. Co.*) [A.-C. motor control] 7,302/10; Rankin [Regulators] 9,530/10; Float Electric Co. and Sandy [Cases for batteries] 9,740/10; Regnart [Lamp-holders] 10,065/10; Siemens Bros. Dynamo Works, Bolton and Willcocks [H.-T. switches] 21,310/10; Lundberg [Plug and socket connections] 847/11; Siemens Bros. Dynamo Works and Laughton [Shade carriers] 950/11.

Telephony and Telegraphy: Egnèr & Holmstrom [Cooling of telephone transmitters] 7,656/10; Carpentier [Telegraph perforator and transmitter] 20,111/10; Siemens Bros. & Co. (*Siemens & Halske A.-G.*) [Telephone exchanges] 21,120/10; Fairweather (*Stein*) [Telephone system] 22,411/10; Bullers, Ltd., and Dagnall [Joints for telegraph poles] 24,368/10; Manny and Binzel [Selective signalling devices] 25,179/10; Gottschalk [Guards for telephone transmitters] 28,397/10; Siemens & Halske A.-G. [Signalling] 2,014/11.

Traction: McGinness [Trolley-head] 7,216/10; Maloney [Monorail cars] 17,075/10; Leslie [Coupling] 20,237/10; Duthie [Direction indicators] 26,538/10; Mitchell [Vacuum brakes] 28,408/10.

Miscellaneous: Gibb and Mavor [Coal conveyors] 8,364/10; Walton and Rayner [Conveyors] 9,729/10; Fisher [Minimising effects of explosions in mines] 14,006/10; Mitchell [Centrifugal drying-machines] 18,743/10; Miram and Seidel [Electromagnetic clutches] 19,786/10; Kraus and Maschinen-fabrik u. Muhlenbauanstalt G. Luther, A.-G. [Magnetic separators] 24,286/10; Robertson [Device for carrying cable, conduit, and rods] 27,448/10; Paillet, Ducretet, and Roger [Discharging electricity from textile materials] 28,552/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Electric Ignition: Julius Pintsch A.-G. [Gas ignition] 29,363/10; Kettering [Ignition system] 5,902/11.

Electrochemistry, &c.: Heil [Primary cells] 473/11; Henri, Heilbronner and Von Recklinghausen [Sterilisation of liquids] 6,178/11.

Instruments: Carpentier, 5,961/11.

Switchgear: A.-G. Brown, Boveri et Cie. [Control of centrifugal pumps] 4,478/11, and [Astatic control of regulators] 4,915/11; Allgemeine Elektricitäts Ges. [Control systems] 6,293/11, and [Motor control] 6,557/11.

Telephony: Ruhmer [Multiple telephony] 6,549/11.

Traction: Klupathy [Signalling] 5,603/11; Harhorn [Hub-motors] 5,870/11, and [Reversing switch for hub-motors] 5,871/11.

The following amended Specification can now be obtained.
A. F. Rietzel [Spot welding of sheet metal] 18,909/05.

Amendment

23,077/05. **Electric Welding.** L. S. Lachman. Owing to an error in the *Official Journal of the Patent Office*, this patent was incorrectly numbered 23,077/04 in last week's Patent Record.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

9,853 of April 20th, 1897. **Photo-printing Apparatus.** B. J. Hall. In apparatus for taking prints from tracings, the tracing and sensitised paper are stretched on the outside of a glass cylinder, through which an arc lamp is lowered at a uniform speed by clock-work gear.

9,915 of April 20th, 1897. **Railway Brakes.** A. Kapteyn (*Westinghouse Brake Co.*). In emergency applications of pneumatic brakes, moderate pressure is at first applied to the brake piston and then gradually increased. Valves to produce this effect automatically are described.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: C. Perdrisat [Converging carbon lamp] 28,401/03.

Distribution Systems, &c.: British Thomson-Houston Co. (*General Electric Co., U.S.A.*). [Machine for cleaning wires before insulating] 28,063/04.

Dynamos, &c.: British Thomson-Houston Co. (*E. M. Hewlett, U.S.A.*) [Arrangement of plant and switchgear in generating station] 26,347/01; Vickers, Sons & Maxim and A. D. Williamson [Control of compound-wound motor] 28,414/02.

Electric Ignition: H. Frenay [Contact maker] 26,286/01.

Electrometallurgy, &c.: H. Hirtz [Diaphragms of nitrated cloth for electrolytic cells] 28,129/04; E. A. Ashcroft [Electrolytic production from salts, of aluminium, sodium, potassium, &c.] 26,813/05, and [Electrolytic deposition from ores of gold, silver, zinc, &c.] 26,813A/05.

Switchgear, &c.: L. Sunderland [Reflectors for theatre battens] 28,252/03.

Traction: P. M. Kling [Tramcar brakes] 27,858/04; T. Stave [Brakes] 26,669/05; O. S. Bragstad [Auto-transformer distribution for A.-C. traction system] 26,689/05.

Miscellaneous: C. J. Simeon, T. Parnall, and W. E. Hipkins [Electric weighing and feeding apparatus] 28,324/03.

ELECTRIC HEATING AND COOKING

A PAPER was read by Mr. S. L. R. Price, on March 9th, before the Dublin Local Section of the Institution of Electrical Engineers, on heating and cooking by electricity. In heating large rooms, &c., by means other than coal fires, pipes are the generally accepted method, whether heated by steam or hot water. These are usually arranged completely round the room, or are fixed in banks at intervals. Such an arrangement evenly distributes the heat, the temperature of the heating surface being comparatively low, so that gentle hot-air currents, flowing rather in a lateral than an upward direction, are set up, due to cross draughts. The heat is thus absorbed in the lower strata of the air in the room where it is required, instead of it being carried up to the ceiling where it is not required, as happens in the case of heaters where the amount of heat given off per unit area of heating surface is high. It being practically agreed that this method of heating is sound in principle, it occurred to the author to deal with the problem electrically; that is to say, have an arrangement of pipes on identical lines with that of the ordinary hot-water or steam system, but without hot water or steam as a heating medium, inserting instead a spiral of some suitable high resistance wire, extending throughout the entire run of the pipe-work, as close as possible to the inside walls of the tubes. This arrangement is arrived at in the best possible way from a mechanical standpoint by winding the wire on to one tube, which is then slipped into a second of just sufficient diameter to permit of its entry. The resistance wire being thus sandwiched between the two tubes is thoroughly supported in every way, and cannot become displaced or sag. The wire is braided with asbestos so as to eliminate as far as possible the trouble of insulating during the process of construction.

In addition to possessing all the advantages of a hot-water system, it does away with one very serious disadvantage, due to the very high specific heat of water and its consequent sluggishness in transmitting heat, for a heater of this description, having very little thermal storage capacity, commences to do useful work within a few moments of being switched on. Experiments have shown that, in order to obtain a temperature of about 170° F. at the face of the tube, a consumption of approximately 50 watts per sq. ft. of tube area is necessary. The cost, of course, works out higher than that of ordinary coke-fired apparatus, if compared over equal periods of working; but, as the electric heater is so easily put in or out of action, the actual working hours can be cut down to at least one-half that of the ordinary coke-fired heater.

The problem of arriving at the amount of heating surface necessary to deal with a specific case is difficult. Prof. Carpenter gives the following formula for rooms which the author has found to work out fairly correctly in some cases :— Area of glass + ¼ area of exposed wall surface + 1/55 cub. ft. required for ventilation. The last term is governed by the number of changes of air required per hour. He suggests three changes per hour for halls, two changes for rooms on the first floor, and one for rooms on upper floors. The writer would, however, suggest three or four changes for ordinary dwelling-rooms.

The author then referred to Mr. W. W. Lackie's Paper, recently read before the Glasgow Section, which pointed out that the lower strata of air in an ordinary dwelling-room, heated by gas or coal fires, is changed about 60 times per hour, the air 3 ft. up 20 times, and the air 6 ft. up only twice per hour. The author then gave the results of some experiments he had made on the question of the spreading of heat in a greenhouse. On one occasion an electric tube-heater as described above, taking 800 watts, was used, and on another occasion a 1,000-watt convector. It was found that, whereas the tube-heater maintained an even temperature throughout the greenhouse, the heat from the convector mostly filtered through the roof. The rise in temperature was actually greater, although the wattage of the heater was less. The usual objection is that electric heating is too expensive; so it may be for constant use, but the author submits that there are a large number of cases in which it may be applied economically, where only intermittent heating is required.

Turning to the subject of electric cooking apparatus, Mr. Price considered that a great deal remained to be done in improving efficiencies and cheapening apparatus. Manufacturers should be able to turn out cheap, high-efficiency apparatus that will stand rough usage. Discussing the hot-plate system, the author thought such apparatus, as at present supplied to the public, was useless for rapid work. The three great drawbacks to this class of apparatus were bad contact between surface of plate and utensil, absorption of heat by the metal of the hot plate before efficient work commences, and loss by radiation. A means for clamping the utensil to the hot plate might minimise the first difficulty; the mass of metal of which the hot plate is generally constructed could be considerably reduced, and, perhaps, a polished metal shield arranged so that heat radiated off the hot plate is reflected back into the sides of the utensil, would make a further increase in efficiency.

Discussion.

Mr. R. N. Tweedy (Messrs. Wm. Coates & Son, Dublin) endorsed the author's condemnation of the hot plate system. He had to deal with a large system of electric ovens in Dublin which had been installed to take the place of gas ovens, and were employed to cook for about 500 persons daily. There were eight ovens built in two sections of four each. They had a total capacity of 38 joints, of an average weight of 30 lb. The dimensions of the ovens were 6 ft. by 4 ft. 6 in. by 3 ft. deep. Heating spirals were fitted at the top and bottom, and the ovens were well lagged. The total energy required was 34 kw., and the capacity of the ovens was 1,140 lbs. of meat. Mr. Tweedy thought that a very important matter for consideration was the great reduction in wastage which occurred with electrical cooking. In this case the current was obtained from the firm's private lighting plant, which was driven by suction gas engines. It was a curious fact that the cost of running the engines was practically nothing, as the amount of coal used while "standing by" was actually greater than when the engine was running and the cooking on operation.

Mr. G. F. Pilditch (Chief Electrical Engineer, Rathmines) thought that electricity was good for baking and roasting, but not for boiling. He advised caution in the matter of fixing the tariffs for this class of supply. The demand would probably coincide with the lighting peak of the load, and very large currents were required, so that it might become necessary to increase the section of the distributing mains, and in some cases even to increase the generating plant.

Mr. C. J. Cummins said that in his experience electric heating was not very expensive, and mentioned a case in Dublin where two large workrooms were heated by nine radiators, and there were in addition four large electric irons. A winter quarter's bill was only seven guineas. He recently tested a hatter's gas iron and found that it took 20 minutes to heat up, whereas, an electric iron was fit for use in two minutes.

Mr. M. Ruddle (City Electrical Engineer, Dublin) thought electric heating was too expensive to use excepting under special circumstances. If the apparatus were arranged in such a way that the air was circulated, he believed that the efficiency of the process could be greatly improved.

Mr. Wm. Tatlow (Chairman) said that Mr. Price's system was particularly satisfactory for greenhouses, because the heated air was equally distributed. If architects could introduce a scheme on the regenerative system, whereby the warmed outgoing air heated the cold incoming air, it would greatly reduce the cost of heating.

Mr. W. J. U. Sowter (Electrical Engineer, Bray) asked if the author had any particulars of an alternating current heating apparatus in which the energy was conveyed to the cooking utensil by eddy currents induced in it. This seemed to him to be a likely solution of the disadvantages of the hot-plate systems which Mr. Price had referred to. He suggested that heating apparatus should be placed across the outers of three-wire systems.

Mr. S. L. R. Price (in reply) thought that all ovens should be ventilated, as it was stated that poisonous gases were given off by meat while cooking. With regard to heating water, he was afraid that the ordinary kitchen range would never be done away with, and, as long as that was in existence, it could quite well be used for the hot water supply. He had tried an arrangement by Messrs. Fuller, in which the current passed through the water to be heated through two platinum plates. It answered very well, but the plates only lasted about six months, so that the cost of renewals was a rather costly matter. Regarding the limitations due to the capacity of distributing mains, he did not contemplate that electric heating would be used to so large an extent for some time to come.

Liverpool Engineering Society.—At a meeting on March 29th a Paper was read by Dr. Gwilym Owen on "Electrons and Röntgen Rays," fully illustrated by experiments.

Forthcoming Books.—Messrs. Constable & Company have just issued the first two volumes of a series of Electric Installation Manuals "By Practical Men for Practical Men." The prices range from 1s. net to 2s. net. The first two volumes to appear deal with (1) Motors, Secondary Batteries, &c., and (2) Arc Lamps and Accessory Apparatus. They will be followed at a short interval by others, amongst which will be :— "Electric Mining Installations," "Mill and Factory Wiring," "Ship Wiring and Fitting," "Bells, Telephones," &c.

EFFICIENCY OF ELECTRIC HEATING APPARATUS

In his concluding Cantor lecture on Electric Heating, at the Royal Society of Arts on March 27th, Dr. J. A. Fleming dealt with domestic heating and cooking apparatus. To heat one pint of water from 60° F. to 212° F. required, theoretically, 190 B.Th.U., or 55 watt-hours (*e.g.*, 330 watts for 10 minutes). As a good electric kettle would do this with 60 watt-hours, its efficiency was over 91 per cent. A gas ring to do the same would consume 0·7 cu. ft. of gas (costing 0·021d. at 2s. 6d. per 1,000 cu. ft.), and gave a thermal efficiency of about 55 per cent. A "Therol" immersion heater taking 300 watts gave on a 24-hour test some 38·4 gallons of water at 110° F. heated up from 60° F. The efficiency worked out at 92 per cent., and the cost 1d. for 5 gallons with current at 1d. per unit. A simple immersion heater for placing in jugs gave an efficiency of 71 per cent. If the jug were lagged the efficiency would be 83 per cent., while if the heater were used in a Thermos flask the efficiency would be nearly 100 per cent. When purchasing an electric kettle the buyer should ask for a test of the efficiency. A figure of from 88 to 90 per cent. was common. A 2-pint 400-watt Prometheus kettle gave 90·5 per cent., and a 570-watt saucepan 93 per cent. There was a certain rate of heating which gave the maximum efficiency, and the apparatus should be designed for this. It should be remembered that an electric kettle or other device could not be forced, but took approximately the same time always to come to the boiling-point. The two different methods of minimising radiation from ovens were lagging with non-conducting material or keeping the outside highly polished. The former took time to heat up, but retained their heat and were highly efficient, while the latter were light and cheap. Comparing generally the cost of gas and electricity for small domestic heating and cooking apparatus, the lecturer stated that with electricity at 0·5d. per unit and gas at 2s. 9d. per 1,000 cu. ft., the cost was equal. However, it should be remembered that there was generally much waste with gas due to the rings being left on, and if this was considered electricity at 1d. per unit was probably not more expensive than gas. A useful rule for calculating the electricity required for cooking was 1 unit per day per person, and 1 unit for the oven. Dr. Fleming considered flexibles, plugs, and switches at 250 volts dangerous in kitchens, and recommended a maximum pressure of 100 volts and flexible steel tubing for all connections. With heating apparatus of the hot-plate pattern, it was essential that both the plate and the bottom of the cooking vessel should be clean in order to get a high efficiency, but this pattern was the most convenient for general use. An advantage of electric cooking was the possibility of control of the temperature—a high temperature to start with, and a lower temperature to finish.

Turning to house warming, Dr. Fleming differentiated between the two kinds of heaters. Radiators heated surrounding bodies, and, besides giving a cheerful glow, produced the maximum temperature where it was required—*i.e.*, in the lower part of the room. Convectors heated the air, and the highest temperature was then at the top of the room. It was perhaps a mistake to have red-hot wires in direct contact with the air, as they dried the air and destroyed organic matter, making it unpleasant to breathe. Electric radiators should not be put in the fireplace. No fireplace was required with electric heating, and ventilation should be by openings with fans if necessary. It was difficult to make comparisons with gas or coal fires, but if current could be obtained at ¾d. per unit there was a saving over gas for ordinary-size rooms. Electricity was not economical for heating very large quantities of water; to compete with a coal-fired boiler it would have to be obtainable at a price of 1/20d. per unit.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

TELEPHONES.—A new telephone catalogue, which is very comprehensive in spite of its small size, is being issued by the Sterling Telephone & Electric Co., Ltd. (200 Upper Thames Street). This contains particulars of direct-acting telephones for domestic and office use, battery and magneto call telephones in great variety for longer distances, inter-communication equipment on the "Primax" system, and special mining telephones. Details of several patterns of switchboards are also given, including those of the common battery lamp signalling type, and instruments on this system are also dealt with. Bells, relays, ringing keys, indicators, and various other accessories, complete the list.

STEAM TURBINES.—The British Westinghouse Electric & Manufacturing Co., Ltd. (Trafford Park, Manchester), have just produced a handsome descriptive book dealing with Westinghouse steam turbines of the impulse type. A full description of these turbines is given, with interesting illustrations of matters of detail, such as the arrangement of the fixed and moving blades, the governing gear, and other special features. A long series of excellent illustrations are also given depicting typical Westinghouse turbine installations, and of particular interest is the section on exhaust, mixed pressure, back pressure, and reducing turbines. The Company ask us to state that they will be pleased to forward a copy to any of our readers on receipt of business card.

Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."

PROTECTIVE APPARATUS.—Messrs. Isenthal & Co. (85 Mortimer Street, W.) have sent us a copy of a comprehensive new catalogue which they have issued dealing with the protection of electrical plant and lines against surges. The subject is dealt with very lucidly and in considerable detail, and a system of protection is gone into employing the well-known Moscicki tubular condenser and the Giles electric valve. The book is divided into a general theoretical section on the nature of the surges to be provided for, a practical section describing the systems recommended to meet various conditions, and finally the catalogue proper, in which the apparatus required is fully set out. The work is worth careful study, and it is the object of the firm to put as much information on this intricate subject in the hands of their clients as possible. We understand that a considerable amount of this apparatus has recently been ordered for South Africa, Australia, China, and Japan.

NAILING AND CLEATING MACHINES.—A catalogue from Messrs. Matthew Wylie & Co. (57 Robertson Street, Glasgow) deals with nailing and cleating machines in various sizes and styles for construction of packing cases and boxes.

SWITCH PILLARS.—A recent pamphlet from the Allgemeine Elektricitäts Gesellschaft describes various patterns of switch and instrument pillars with and without regulator handwheels.

PLANING MACHINE DRIVE.—Another publication from the A.E.G. calls attention to a system of electrical reversing planing machine drive, and gives a list of engineering firms on the Continent who have adopted it.

LOCAL NOTES

Barnstaple: *Plant Extensions.*—The Council have asked the Islington Borough Council to allow Mr. Gay, their Electrical Engineer, to act in a consulting capacity in connection with the new plant which is to be installed.

Belfast: *Tramway Accounts.*—The accounts of the tramway department to March 31st show a net revenue, after meeting capital charges, of £54,050 16s., which is an increase of £7,755 over the previous year. Depreciation fund is credited with £13,000, and reserve fund with £16,730.

Darlington: *Tramway Loss.*—There was a loss of £1,426 upon the tramways undertaking for the year to March 31st; and as it is also deemed necessary to set aside £1,000 for depreciation, there is a net loss of £2,426.

Larne: *Purchase of Electricity Co.*—Mr. W. J. U. Sowter, Electrical Engineer to the Bray Council, has been retained by the Larne Council to prepare a report upon the proposed purchase of the Larne Electric Lighting Co.

Leeds: *Tramway Supply.*—The Electrical Engineer and the Tramways Manager have been instructed to proceed with a scheme for converting the present 25-period supply from the tramway power station to 50-period supply in order to unify the supply from the tramway and lighting power stations.

Manchester: *Tramway Arbitration.*—Sir David Harrel commenced the arbitration proceedings on Monday in connection with the dispute between the Tramways Committee and their employees.

Newcastle-on-Tyne.—Mr. J. A. Rodgers, who recently resigned the chairmanship of the Tramway Committee as a protest against the action of the Corporation in transferring £12,000 from tramway profits to the relief of taxes, has consented to remain on the Committee.

St. Helens: *New Turbo-alternator.*—On Wednesday last week a new 1,000-kw. Westinghouse turbo-alternator was put into operation. The machine runs at a speed of 3,000 r.p.m., and generates at a pressure of 6,600 volts. The steam consumption guaranteed is 15·9 lb. of steam per kw. hour at full load, but tests have shown this to be 1·63 per cent. better than the guarantee.

Hosted by Google

Scarborough: *Tram Service Resumed.*—The tramway service having been renewed, and the Company having given an undertaking to continue the service during next winter, the Corporation have asked the Board of Trade to defer action in regard to the suggested cessor of the Company's powers.

Southend-on-Sea: *Electricity and Tramway Profits.*—Although the accounts of the electricity and tramways departments have not yet been issued, we understand that the net profits of the former for last year amount to £8,680, and of the tramways to £5,100. Of the profits of the electrical undertaking, £1,800 have been set aside for meters and wages of permanent employees, for which the Local Government Board will not grant loans; £1,500 have been transferred to reserve, and the balance handed over in relief of rates. Of the tramway profits, £1,500 have been set aside for doubling a portion of the track, £2,000 to reserve, and £1,000 to relief of rates, the balance being carried forward.

Worcester: *Plant Extensions.*—The scheme of the Borough Electrical Engineer to instal three-phase generating plant in connection with the supply to Messrs. Heenan & Froude has been referred back for further consideration. The total cost of the proposed extension is £7,100.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Ashton-under-Lyne.—The Corporation electricity works are to be remodelled at an estimated cost of £30,000. It is stated that several large firms have expressed their willingness to establish works in the borough if electrical power is available at a cheap rate.

Barmouth.—The Council is considering an electric lighting scheme, which has been prepared by Mr. Charles Balbiani.

Blackburn.—The Electrical Engineer has submitted a report on extensions at the electricity works.

Bradford.—The City Electrical Engineer has recommended the addition of a further 3,000-kw. turbo-generator with switchgear at an estimated cost of £20,000.

Bulgaria.—The *Board of Trade Journal* states that the conditions of tender for the installation of electric lighting at Varna may be seen at 73 Basinghall Street, London.

Derby.—Tenders are invited for inverted rotary converters, E.H.T. cables, and E.H.T. switchgear. Particulars from Borough Electrical Engineer.

Epsom.—A scheme of extensions into the Ewell district is being prepared by the Electrical Engineer. The estimated cost of mains and services is put at £1,300.

London: *Battersea.*—The Finance Committee of the L.C.C. recommend sanction to a loan of £2,000 for mains.

Islington.—Application is to be made for a loan of £6,500 for low-tension mains, meters, services, and transformers.

Shoreditch.—The Finance Committee of the L.C.C. recommend sanction to a loan of £11,236 for mains, house services, and meters.

Newcastle-under-Lyne.—Instructions have been given for extensions of plant at the Council's generating station.

Oulton Broad.—A scheme for the supply of electrical energy from the works of the East Anglian Ice Co. is under consideration by the Council.

South Shields.—A new scheme for the extension of buildings and plant at the Corporation power station at a cost of £10,080 is recommended. A loan of £7,580 is to be applied for, the balance being taken out of reserve fund. New plant will consist of a 1,500-kw. turbine driving a 1,000-kw. direct-current, and a 1,000-kw. alternating-current generator.

Woodbridge.—Messrs. Foot & Milne have presented a scheme of electric lighting to the Council.

WIRING

PROVINCES.

Ashton-under-Lyne.—Council school. Architect, Mr. E. Woodhouse, 59 Warrington Street.

Birmingham.—New police station.

Bolton.—New infants' school. Lancashire Education Committee.

Bootle.—Proposed memorial hospital.

Brighouse.—School. Architects, Messrs. Sharp & Weller, 32 Bradford Road.

Bury.—Tenders are invited for the wiring and fitting of the new Chamber Hall power station. Borough Electrical Engineer.

Colchester.—Asylum buildings. Architects, R. L. Curtis & Sons, Finsbury Square, London.

Dublin.—Tenders are invited by April 26th for the electric lighting of Charleville Mall Public Library extension. Particulars from the Public Libraries Committee at City Hall, Dublin.

Dundee.—Cinematograph Theatre in Hawkhill. Mr. A. E. Bennall.

Dunfermline.—New drill hall for Territorial Association.

Edinburgh.—New drill hall at Gilmore Place.

Hertford.—School. County Surveyor, Hatfield.

Motherwell.—New offices for Town Clerk.

Newark.—Hospital buildings in Barnaby Road. Town Surveyor.

Newcastle-on-Tyne.—New branch post office at Heaton. H.M. Office of Works, London.

Romford.—New post office. H.M. Office of Works, London.

Sheffield.—Rebuilding of Corporation Street baths. New wing for Applied Science Department of the University.

Worthing.—School of Art. Mr. L. Thompson, Thurloe House, High Street,

MISCELLANEOUS

Brighton.—The tramway lines in Lewes Road are to be re-anchored and re-seated at an estimated cost of £1,650.

Dudley.—Tenders are invited by April 19th for service cables, electrical fittings, arc lamp carbons, carbon filament lamps, and general stores. Particulars from the Borough Electrical Engineer.

East Indies.—The *Board of Trade Journal* states that a group of Chinese capitalists has applied to the Government of the Netherlands East Indies for the working of electric tramways in Batavia.

London: *L.C.C.*—Additional car traverses are required for the Streatham, Camberwell, and Hammersmith car sheds.

A large manufacturing firm desires to be placed in communication with makers of electric signs. The name of the firm in question is on file at this office.

TENDERS RECEIVED AND ACCEPTED

Bolton.—The Tramway Committee have accepted the tender of Mr. Chas. H. Blume for insulating compound.

Burnley.—The Council have decided, subject to the sanction of the Local Government Board, to accept the tender of the British Westinghouse Co. for a 1,500-kw. turbo-alternator at £6,433.

London: *L.C.C.*—The following tenders have been accepted for the supply of tramway parts, equipments, &c., for the year ending April 30th, 1912: Motor and generator spares, British Westinghouse Co.; Dick, Kerr & Co. Switchgear spares: Brecknell, Munro & Rogers; Dick, Kerr & Co.; British Westinghouse Co. Motor and generator brushes: Le Carbone; Sloan Electrical Co.; W. Geipel & Co. High and low tension cables, fuse wires, and cotton-covered copper wire: Western Electric Co.; W. T. Henley's Telegraph Works Co.; Liverpool Electric Cable Co.; London Electric Wire Co.; and Midland Electric Wire Co.

The following tenders have been received for the electric lighting of the trade school for girls, Belvedere Place, Southwark: G. Weston & Sons, Ltd., £275; Tilley Bros., £347 17s.; Johnson & Phillips, Ltd., £357; A. Hawkins & Sons, £369; Barlow Bros. & Co., £382 16s.; E. Newbald, £396; G. Harland, Bowden & Co., £423; Tredegar & Co., £432; Mann, Egerton & Sons, Ltd., £462 13s. The tender of G. Weston & Sons is recommended for acceptance.

Hammersmith.—The following tenders have been received for the supply of 24 frames and sub-station switchgear: Spagnoletti, £269; Ferranti, £271; Bertram Thomas, £283 10s.; Johnson & Phillips, £289; British Thomson-Houston Co., £319; Siemens Bros., £339; General Electric Co., £358; Electric & Ordnance Accessories Co., £366; British Westinghouse Co., £448; Electric Construction Co., £462; Reyrolle & Co., £529. The first-named tender is recommended for acceptance.

For the supply of two 100-kw. and two 200-kw. transformers the following have been received: British Electric Transformer

OSRAM-LAMPS

Hosted by Google

Co., £477; British Thomson-Houston Co., £492; W. E. Burnand & Co., £499; British Westinghouse Co., £544; Foster Engineering Co. (two 100-kw. transformers only), £180. In view of satisfactory past experiences with machines of the British Electric Transformer Co., this firm's tender is recommended for acceptance.

Fourteen tenders have been received for water-tube boilers, superheaters, forced-draught furnace, mechanical stokers, economisers, &c., ranging from £5,007 to £9,602. In a report, the Electrical Engineer states that the two most favourable schemes are by the Stirling Boiler Co., at £5,602, and Messrs. Frazer & Chalmers, £9,510. The latter is for Messrs. Frazer & Chalmers' dust-fired boiler, which, whilst considered very attractive by the Electrical Engineer, is put on one side for the reason that the extra price outweighs the advantages. He recommends the acceptance of the tender of the Stirling Boiler Co. at £5,602, plus £229 for a larger air heater to enable the efficiency to be increased from 80 per cent. to 82½ per cent.

Tenders of the Universal Electrical Manufacturing Co. at £25 for 200 D.P. ironclad fuse boxes, and £86 15s. for 17 c.c. feeder pillars with switches and fuses have been accepted.

South America.—The British Westinghouse Co. have received an order from R. Jeffry for Pedro Perfetti, Valparaiso, for Tree Marias Oficina for two 75-kw. 230-volt D.C. generators and control gear, one 80-h.p., four 13-h.p., two 31-h.p. 220-volt D.C. motors and control gear.

Tonbridge.—The tender of the Electric Apparatus Co., Ltd., for a year's supply of motor type meters has been accepted.

West Hartlepool.—The tender of the Bastian Meter Co. has been accepted for 2½-ampere and 5-ampere meters.

Messrs. Venner & Co. have received orders for the supply of Chamberlain & Hookham meters during the ensuing year at Belfast, Barrow, and West Hartlepool. The Belfast Corporation have also accepted this firm's tender for "Venner" time switches.

APPOINTMENTS AND PERSONAL NOTES

Mr. A. L. Ballard, Gold Medallist of Faraday House (1909), has been appointed to the Assistant Lectureship in Electrotechnics at the South African School of Mines, Johannesburg (Transvaal University), at a commencing salary of £300 per annum. Whilst a pupil of Faraday House, Mr. Ballard served the practical part of his training with Messrs. Robey & Co., Ltd., of Lincoln, and at the works of the General Electric Co., Ltd., Witton, Birmingham.

Mr. J. H. Rider has been appointed President of the South African Institute of Electrical Engineers.

Mr. D. C. Redfern has been appointed Mains Superintendent at the Stoke-on-Trent Electricity Works at a salary of £130 per year. There were fifty-seven applications for the post.

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £56 to £56 10s. per ton (last week, £56 15s. to £57).

Dissolution of Partnership.—Messrs. Robson & Coleman (Haymarket Lane, Newcastle) have dissolved partnership. Mr. R. E. Robson is carrying on the electrical business, and Mr. A. C. Colman is turning his attention to patent agency and consulting work.

Liquidations.—The petition of Messrs. Siemens Bros. Dynamo Works, Ltd., for the compulsory winding up of Arc Lamps, Ltd., was withdrawn on Tuesday before Mr. Justice Swinfen Eady.

The Rosario Electric Supply Co. is to be wound up voluntarily. Mr. H. E. Benthall, 52 Moorgate Street, London, is liquidator. A meeting of creditors will be held at the above address to-day (Thursday) at 12 noon.

Electrocars, Ltd., is to be wound up voluntarily. Mr. J. E. Denney, 3 Great St. Helens, London, is liquidator.

The Welsbach Incandescent Gas Light Co., Ltd., is to be wound up voluntarily for the purpose of reconstruction. Mr. H. E. Spinney, 344–354 Gray's Inn Road, London, is liquidator. A meeting of creditors will be held at that address on April 19th at 12 noon.

Bankruptcies.—A first and final dividend of 8¾d. in the £ will be paid on April 20th at the offices of Messrs. Corfield & Cripwell, 119 Finsbury Pavement, in the bankruptcy of J. A. Bauer, trading as the Electrical and General Engineering Co.

The discharge of R. Russell, Electrical Engineer, Felsham Road, Putney, has been suspended for two years.

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Hastings & District Electric Tramway Co.—At the annual meeting last week a scheme for the reduction of the capital from £500,000 to £372,942 10s. was sanctioned. It was stated that the work of the past three years has shown conclusively the impossibility of paying the interest on the £200,000 6 per cent. cumulative preference shares and at the same time to make adequate provision for depreciation.

South Wales Electrical Power Distribution Co.—Mr. W. Gascoyne Dalziel presided at the annual meeting last week, and mentioned that the generating costs had been reduced by about 45 per cent. between September, 1907, and December, 1910. This result had been brought about by the use of steam turbines, and the additional machinery now being installed would, it was hoped, lead to further economies. Two large and important colliery companies had recently decided to take all their electrical energy from the company, and contracts had been let for the construction of the power lines to connect up these collieries. An additional £20,000 capital was necessary in this connection, which the Treforest Co. had arranged to find.

Tynemouth & District Traction Co.—There was a net balance of £5,068 for the year 1910, and, after placing £500 to reserve and £1,000 to debenture redemption fund, a 4 per cent. dividend is recommended for ordinary shares, carrying forward £187.

Cork Electric Tramways & Lighting Co.—After placing £5,000 to depreciation, a 4 per cent. dividend is recommended on the ordinary shares for 1910.

Gateshead & District Tramway Co.—At the annual meeting last week a suggestion that the £10 shares of the company should be divided into £1 shares was put on one side for the present, the chairman remarking that it would necessitate a special Act of Parliament.

Metropolitan Electric Tramways.—Mr. E. Garcke, who presided at the annual meeting last week, had a very satisfactory statement to make as to the past year's work. The development of the traffic has been so rapid that the company's cars were unable to cope with it, and cars had to be hired. The fact that the revenue per car mile was not so good as in previous years was due to the number of lines now serving sparsely populated districts. Their investment in the North Metropolitan Electric Power Co. still continued a good one, the dividend for the past year amounting to 6 per cent. in addition to the bonus. During the year, an issue of £250,000 second debentures had been made, and it was not expected that any further additions to the capital would be needed, after the balance of the ordinary shares, viz., £8,000, had been offered to the shareholders. The tramway scheme as originally designed was now practically complete. The directors thought highly of the use of trolley omnibuses for out-lying districts.

Calcutta Tramways Co.—A final dividend, making 6 per cent. for 1910, is recommended, adding £8,000 to depreciation, and carrying £1,662 forward. The traffic receipts increased by £10,546 during the year.

Obituary.—We regret to announce the death, through an accident, of Mr. Wm. Middleton, Assistant Works Superintendent to the Newcastle & District Electric Lighting Co., Ltd. Mr. Middleton was examining the back of a switchboard at the Close power station of the Company on Thursday afternoon, when a short circuit occurred. His face and hands were badly burned, and the upper part of his clothing was in flames. A doctor was immediately sent for, and he was conveyed to the Gresham Private Hospital, where he succumbed to his injuries on Friday morning. At the coroner's inquest the jury returned a verdict of "Death from shock following electric burns accidentally sustained," and expressed the opinion that a partition between the positive and negative bars should be provided in future to prevent danger from any accident or short circuit. Mr. Middleton was only thirty-seven years of age, and had been in the service of the above Company for fourteen years. He served his apprenticeship with Messrs. C. A. Parsons & Co., and as quite a young man was occupied in responsible positions. He was married in 1899, and leaves a widow and four young children.

Messrs. Connolly Bros.' Affairs.—Two debenture-holders in Messrs. Connolly Bros. obtained, a short time ago, the appointment of receivers, one in the Chancery Court and the other in the County Palatine Court. Subsequently, Mr. Justice Parker, in the Chancery Division, made an order restraining the proceedings in the County Palatine Court pending those in the High Court. On Thursday the Appeal Court, consisting of the Master of the Rolls and Lords Justices Fletcher-Moulton and Buckley, dismissed an appeal against the decision, on the ground that the learned judge in the County Palatine Court appointed the receiver in those proceedings after the other receiver had been appointed in London.

BINDING "ELECTRICAL ENGINEERING." — Vol. VI. of "Electrical Engineering" (Jan.—Dec. 1910) closed with our issue of December 29th, 1910. An index for the volume is now ready, and copies may be ordered from any newsagent or bookseller at the price of 1d. each (or post free, 2d.). Binding Cases, including index, price 2s. each, post free 2s. 4d. (Abroad 2s. 6d.) Readers can have their volumes bound by their own bookbinder; or, they may send their numbers to us, carriage paid (with the reader's name and address), and a remittance of 4s. 6d. under separate cover. The volumes will then be bound and returned carriage paid to any address in the United Kingdom, or carriage forward to the Colonies or abroad.

SUMMARY

The power station at the Trollhättan Falls erected by the Swedish Government, is designed for an ultimate output of 80,000 h.p., but something like 200,000 could be made available. Four turbines are already in place, each 10,000 h.p., and these, which run at 187·5 r.p.m., are coupled to some of the largest alternators yet constructed. (Page 203.)

Some illustrated particulars are given of the latest designs of Westinghouse impulse steam turbines. (Page 205.)

A Paper read recently at the Institute of Naval Architects described a new form of electro-hydraulic steering gear. (Page 206.)

The supply of electricity in rural districts was discussed at a recent meeting of the Yorkshire Section of the Institution of Electrical Engineers, when Mr. W. B. Woodhouse read a Paper describing the work done by the Yorkshire Electric Power Co. in this direction. (Page 207.)

The report of the Special Committee of the Tramways and Light Railways Association on speed indicators has now been issued. The Committee are not in favour of fitting all cars with speed indicators, but report satisfactory working of most of the instruments tested. (Page 208.)

Mr. C. Vernier's Paper on the laying and maintenance of cables has been further discussed by the Newcastle Local Section of the Institution of Electrical Engineers. (Page 208.)

A letter from Mr. H. Richardson (city electrical engineer, Dundee) continues the discussion on electricity meters. (Page 209.)

Substantial reductions are being made in the prices of high candle power metal filament lamps. Some interesting figures of the life of these lamps are also available. (Pages 209 and 214.)

Among the specifications published by the Patent Office on Thursday was one by V. Hope for an enclosed replacement fuse consisting of a subdivided carrier containing the several fuse wires, which is enclosed in the holder and can readily be replaced.—Siemens Bros. Dynamo Works describe improvements in the construction of oil-switches of the carriage type to prevent exposure of the live parts when the carriage is drawn out for cleaning.—A method of reducing the liability

of the breakage of metal filaments at the supports by coiling the filament a few turns round the support to limit its movement at this point, is covered by G. F. Attwood.—A patent for a method of jointing filaments to supports has been granted to Pope's Electric Lamp Co., in spite of opposition. (Page 210.)

A PAPER on the mechanical design of induction motors, by Mr. H. L. Smith, bringing out some interesting points, was read before the Rugby Engineering Society recently. (Page 211.)

THE Cruse Controllable Superheater Co. have been successful in their action against Willans & Robinson, Ltd., to recover damages for defects in superheaters manufactured for them by the latter firm. The damages awarded were £3,535, but it is stated that the total costs of the action, together with damages, amount to over £20,000. (Page 211.)

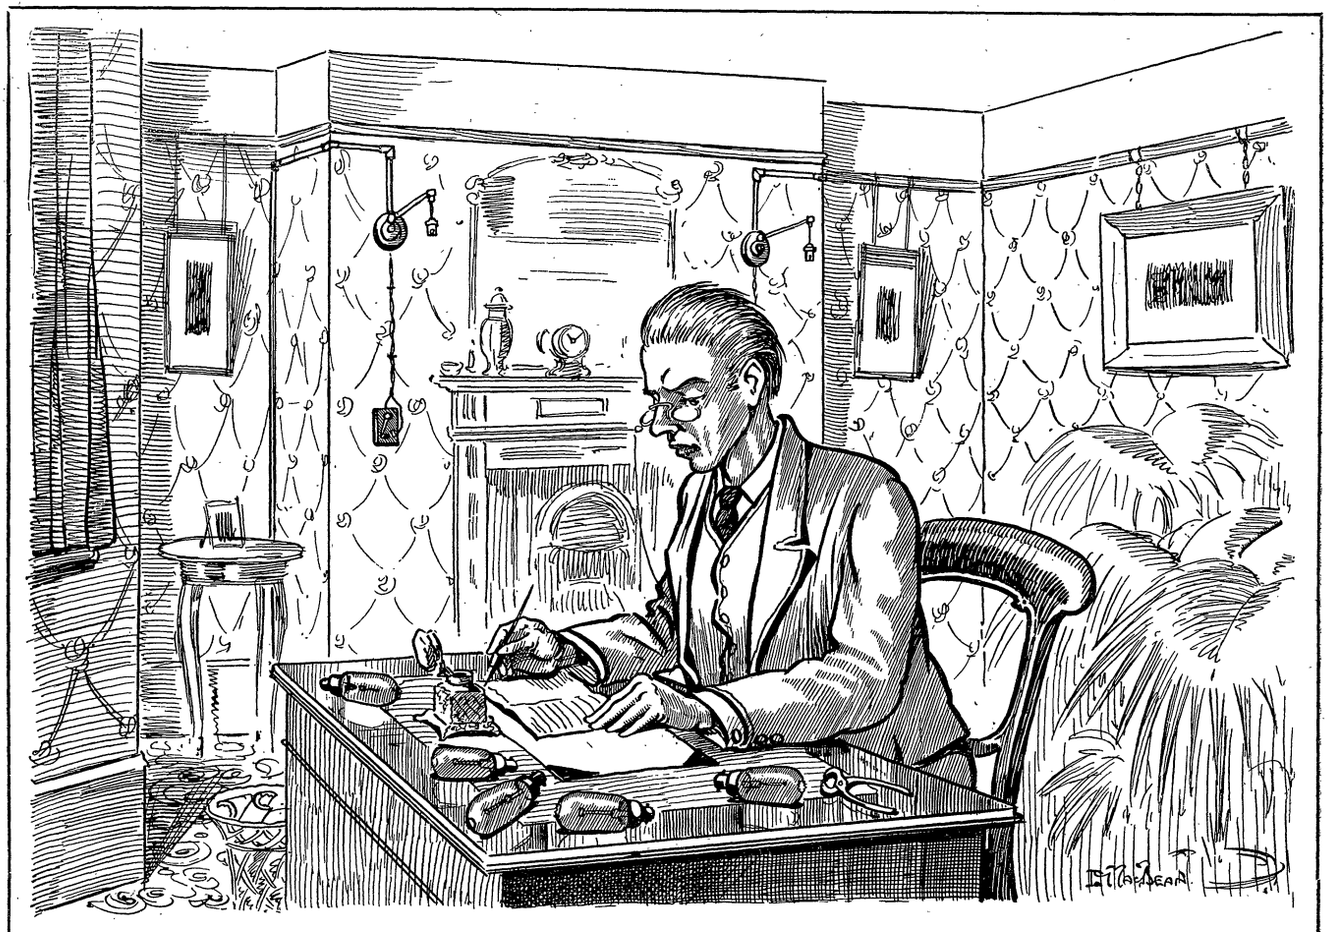
THE costs of the arbitration in connection with the Torquay Tramway change over amounted to £1,399.—It is proposed to transfer certain portions of the Kent Electric Power Co.'s area to the East Kent Electric Supply Co.—The Ealing Council have refused to adopt a suggestion made by the Local Government Board inspector to purchase meters out of revenue.—All the remaining street gas lamps in Watford are to be converted to metal filament lamps. (Page 212.)

APPLICATIONS are to be made for loans as follows:—Barnsley, £16,100; Sale, £5,900; Aldershot, £2,500; Altrincham, £6,150; and Lowestoft, £3,000. An inquiry will be held shortly concerning a loan of £128,129 for electrical extensions at Dublin. Trunk mains, feeders, and distributers are required at Haslingden; a police fire alarm system at Salford; cooling tower and switchboard extensions at Walthamstow; generator, condensing plant, and cooling tower at Luton; a 1,500 kw. turbo-alternator at Fulham; and mains at St. Pancras. (Page 212.)

MESSRS. BABCOCK & WILCOX made a net profit of £425,443 in 1910, and a dividend of 8 per cent., together with a bonus of 8 per cent., is declared upon the ordinary shares. (Page 215.)

ARRANGEMENTS FOR THE WEEK

SATURDAY, APRIL 22ND.
Association of Mining Electrical Engineers.
2 p.m. Newcastle Branch. Visit to electrical installation at Chopwell Colliery.



MONDAY, APRIL 24TH.
Illuminating Engineering Society.
8 p.m. At Royal Society of Arts. (1) "The Ratio of Light to Illumination," by H. T. Harrison. (2) "Some Notes on the Effect of Wall-papers upon the Illumination of Interiors," by P. J. Waldram.

TUESDAY, APRIL 25TH.
National Electrical Manufacturers' Association.
8 p.m. At Institution of Electrical Engineers, Victoria Embankment. "Foreign Compared with Home Industrial Finance," by L. Joseph.

WEDNESDAY, APRIL 26TH.
Electrical Trades' Benevolent Institution.
7 for 7.30 p.m. Festival Dinner at Hotel Cecil.
Faraday House Old Students.
7 for 7.30 p.m. Annual Dinner at Holborn Restaurant.
Institution of Electrical Engineers: Birmingham Section.
7.30 p.m. At the University. "Battery Economics and Battery Discharge Arrangements," by A. M. Taylor.

THURSDAY, APRIL 27TH.
Imperial Education Conference.
At the Foreign Office. (1) "Engineering Education," by J. A. Ewing, F.R.S. (2) "Higher Technical Instruction," by J. H. Reynolds.
Institution of Electrical Engineers.
8 p.m. At Victoria Embankment. "Battery Economics and Battery Discharge Arrangements," by A. M. Taylor.

SATURDAY, APRIL 29TH.
Old Ferrantians.
7 for 7.30 p.m. Dinner at Trocadero Restaurant, London.

MR. FLECKS WRITES TO HIS LAMP SUPPLIERS:—"Dear Sirs, The lamps you supplied me with to my recent order were all defective and burnt out immediately on being connected to the circuit, the bulbs were also very roughly finished, and I had to remove a projecting spike of glass from each before taking them into use."

THE TROLLHÄTTAN POWER SCHEME

THE river Göta, in Sweden, flows from Lake Venern, which ranks as the third largest lake in Europe, and is navigable throughout the whole of its length of 56 miles except through the Trollhättan gorge and one or two other points, and from the sixteenth century onwards schemes have been carried out with a view to completing, by canals with the necessary locks, a practicable waterway from the great lake to the sea. At the present time a scheme is in hand by the State for the enlargement of the existing Trollhättan ship canal, which is expected to be completed in 1915. We are, however, more particularly concerned in this article with the way in which the difference of levels on this part of the river, the disadvantages of which to shipping are being removed by these canals, has further been made of use to the community as a source of power on a large scale.

The total difference of levels between Lake Venern and the sea is about 144 ft., of which about 105 ft. is actually in the Trollhättan series of falls, and the minimum flow of the river is over four million gallons per minute, rising to a maximum value of about 12 million gallons per minute. The enormous storage of Lake Venern, which has a surface of no less than 2,150 square miles, can, however, be utilised so that the total power which could actually be relied upon all the year round reaches the total of 200,000 h.p. The water-power rights for the whole river are owned by the State, who commenced in 1906 the construction of a station capable of dealing with some 3,300,000 gallons per minute, corresponding to about 80,000 h.p. at the turbines. The first portion of this station was inaugurated on October 28th, 1910, and the whole station is expected to be complete during the present year. £622,000 has so far been spent on the plant.

A general plan of the system is given in Fig. 1. The hydraulic part of the work included the construction of an intake dam at the side of the river well above the falls, with gates operated electrically and elaborate ice barriers at the head of a canal more than three-quarters of a mile in length, cut out of the solid rock and lined with masonry. There is also a regulating dam across the main river at the top of the falls. The canal leads to the head of the pressure tunnels leading down to the power station. At a future date a further canal is to be constructed, bringing an additional supply of water from the new ship canal, which it is intended ultimately to construct. The water is taken from the distributing basin or forebay, through eleven inclined tunnels in the rock, lined with concrete and steel plates. Each has a total length of 197 ft.; eight of them are 14 ft. in diameter, and are for supplying the large turbines, while the remaining three, for the auxiliary turbines, are about 4 ft. in diameter. Sluice valves are placed at the head of each of these, arranged to be closed rapidly by electric power from the power-house

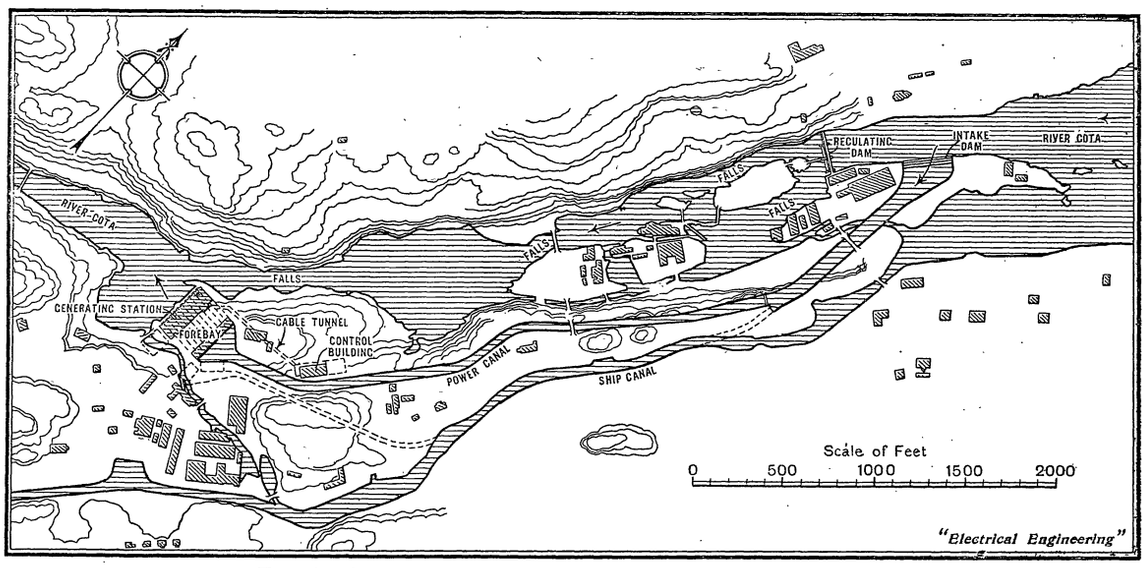

FIG. 1.—SKETCH MAP OF TROLLHÄTTAN FALLS POWER SCHEME.

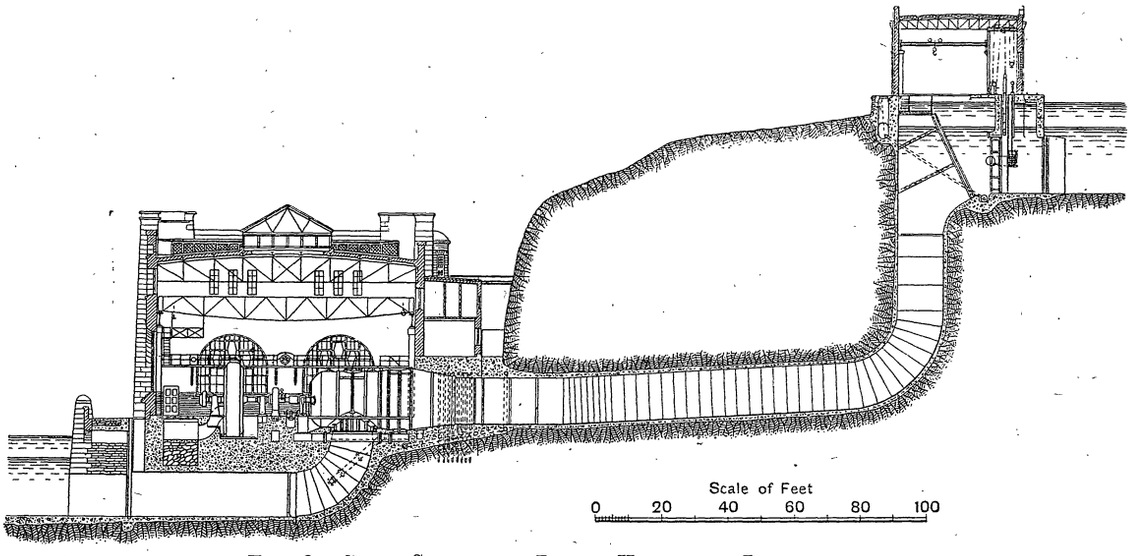

FIG. 2.—CROSS SECTION OF POWER HOUSE AND INTAKE.

Hosted by Google

in case of necessity. They are elaborately protected by suitable grids against ice. A by-pass overflow channel direct down to the river is provided in case of an abnormal rise in the level of the canal or a sudden check of the water due to all the turbine regulating valves closing at once. The speed of the water at full load through the ice grid is about $3\frac{1}{4}$ ft. per second. A section of the power station, showing the arrangement of the pressure tunnels and generating plant, is given in Fig. 2.

The turbines in the power station are of the horizontal shaft pattern direct coupled to the generators. The main turbines will be eight in number, each rated at a normal output of 10,000 h.p. at 187·5 r.p.m., with a net head of 103 ft., but they are each capable of developing a maximum output of 12,500 h.p.

Each large turbine has two wheels in the same case, and has its own governing mechanism, with oil pumps, mechanical relays, &c., but any governor can, if necessary, be connected up to control any other turbine. The smaller turbines working the exciters are of the single wheel pattern, each capable of an output of 500 h.p. at a speed of 410 r.p.m. The four turbines forming the initial instalment of this equipment, were supplied by the Swedish firm of Nydqvist and Holm, and practically the whole of the electrical equipment, including the large generators, was supplied by the Allmänna Svenska Elektriska Aktiebolaget, of Vesteras. The main turbines are of the double Francis horizontal type, in centre casings of steel plate. The front cover, as well as the inner parts, are of cast steel. All the bearings have ring lubrication, and are accessible through vertical inspection shafts. The governors are worked by oil under pressure and have double return gear; 82 per cent. efficiency is guaranteed at three-quarter load.

The generators are wound for a pressure of 10,000/11,000 volts, three-phase, 25 cycles, and a continuous load of 11,000 k.v.a. each. They are completely enclosed, and are ventilated by air being drawn through the cases from ducts coming from under the machine-room floor by fans carried on the rotors. The heated air is expelled into the open air in summer, but can be used in winter for the warming of the various buildings. The two smaller generators, which are used for excitation, station lighting, and auxiliary power purposes, are of 350 kw. each, and generate continuous current at 220 to 300 volts. They work in conjunction with a 4,000 ampere-hour battery.

The excitation of the main generators is not controlled, as is usually the case, by series rheostats, but by means of boosters direct coupled to each set, which can produce any pressure from 110 to 220 volts, so that by opposing or aiding the pressure of the continuous-current bars any voltage from 0–300 may be applied to the fields of the generators. The continuous-current switchboard is placed in the turbine room, but all the high-tension switchgear is situated in a separate building. The cables from the main generators to the switch building are taken through a pair of tunnels about 650 ft. in length. Each tunnel contains at present the cables for two generators. The reason for this wide separation of the generating and distributing stations was purely the configuration of the rocky ground. The distributing station contains, as well as the main switchgear, the transformers for raising the voltage from 10,000 to 52,000 volts, at which pressure most of the outgoing transmission lines are worked. In the centre of the building is the control room, from which all the main generator and feeder switches are worked by electromagnetic remote control. The field regulation of the alternator is also controlled from this point. An elaborated system of signalling shows the attendants the state of all connections. Diagrams of connections with automatically moving representations of switches interlocked with the control switches show at a glance whether each main switch throughout the system is open or closed. Telephones connect the control room with the power station, and the transformer chambers, but in the case of the main generating plant, the orders are transmitted by visual electric telegraphs in order not to rely upon the telephones being audible above the noise of the running machinery. The building also contains an erecting and repair shop, provided with a crane, and a laboratory.

The main transformers are arranged in four cells, each containing the group of three single-phase transformers belonging to each generator. Each single transformer is rated at 3,670 k.v.a. They are oil-immersed and water-cooled. The cells are completely sealed up in case of fire, and arrangements are made so that the oil can be quickly run off if it catches fire. Special alarm signals are also provided to indicate any interruption in the cooling water circulation, as well as if the temperature of the oil exceeds a certain value. A group of four electrically-driven pumps are provided for the water circulation, and to provide the water jets for the lightning arrestors. Two of these pumps are held as spares, and there are elaborate systems of tanks and piping, both for this water service and for filling, emptying, and purifying the oil for the transformers.

Some of the outgoing lines are worked at 10,000 volts, and some at 50,000 volts, and the circuits can be sectionalised so that the individual generators can be run on separate lines or groups of lines quite independently. The connections are also so arranged by means of duplicate sectionalised high-pressure and low-pressure 'bus-bars, that any group of transformers can be coupled to any generator, so that the utmost flexibility is secured in view of breakdowns in any part of the equipment. The main switches are all arranged so that they switch in the machines or feeders through a resistance, before coupling them right up, to prevent surges, and all current-carrying parts of the equipment are designed to withstand the mechanical forces that would be produced by the short-circuit current of the eight generators together. Overload relays of the induction type are employed. The aerial circuits are protected, so far as discharges involving large amounts of energy are concerned by lightning arrestors of the horn pattern in conjunction with water jets, as well as oil resistances. Multicylinder arrestors are also used to protect against small disturbances.

With the exception of the cables in the tunnels between the generator and switch houses, all the H.T. conductors are bare metal mounted on porcelain insulators; bars are used for the 10,000-volt circuits, and tubes for the 50,000-volt circuits. The different phases are kept separated by concrete partitions in iron framing. The 10,000-volt conductors have everywhere 8 in. clearance from earthed surroundings, and the clearance round the 50,000-volt conductors is 16 in. Through the tunnels the cables lie each in its own masonry trough covered with sand. The various cells containing high-tension apparatus are separated by concrete partitions through which suitable insulators lead where a conductor has to be passed through. The cells containing the oil switches are entirely closed in, and provision is made for draining off the oil rapidly in event of the bursting of an oil container.

As already stated, the longer transmission lines are fed at 50,000 volts, while the distribution in the nearer neighbourhood of the station is at 10,000 volts. Energy is in neither case actually supplied to a consumer at 50,000 volts, but is transformed down to 10,000 volts, or in some cases to 3,000 or 6,000 volts, in sub-stations, which, like the generating station, are the property of the State. The secondary distribution networks are also erected and maintained by the State, and the cost to the consumers is reckoned to include the losses in transformation at the sub-stations. The lines already constructed aggregate some 76 miles.

All the 50,000-volt lines are of copper, arranged as a general rule six to a tower, protected by an earthed iron cable mounted on the same poles. Lines of this nature are erected or are in course of construction to the towns of Skara, Gotenburg, and Alingsas. The Skara line is equipped with pin-type insulators, while suspension insulators are used on the other lines except at towers where side stresses due to angles are taken. These strain towers are placed as a rule about 1 kilometre apart, and are substantially constructed to resist forces in any direction, while the intermediate supports are rigid only in a direction at right angles to the line, and have a certain elasticity in the direction of the line. In the case of lines composed of six 70 mm. wire, these supporting towers are about 660 ft. apart, and where 16 mm. wires are used they are about 460 ft. apart.

The 10,000-volt lines, where the largest amounts of energy are transmitted, are of aluminium, but the smaller lines are of copper. Pin insulators are used throughout, and steel towers similar to those for the 50,000-volt lines are used, except for a few of the lighter lines, where impregnated wood poles are employed. Transformer sub-stations are placed at various points of the system.

The price charged to the various local authorities and private consumers to whom power is supplied, varies with the distance from the power station, but is in all cases very low. Contracts have already been entered into with the towns of Gotenburg, Skara, Skövde, Alingsas, and other minor places. The State is also favouring the establishment of industries requiring cheap power in the district of Trollhättan itself by granting manufacturing sites on very favourable terms.

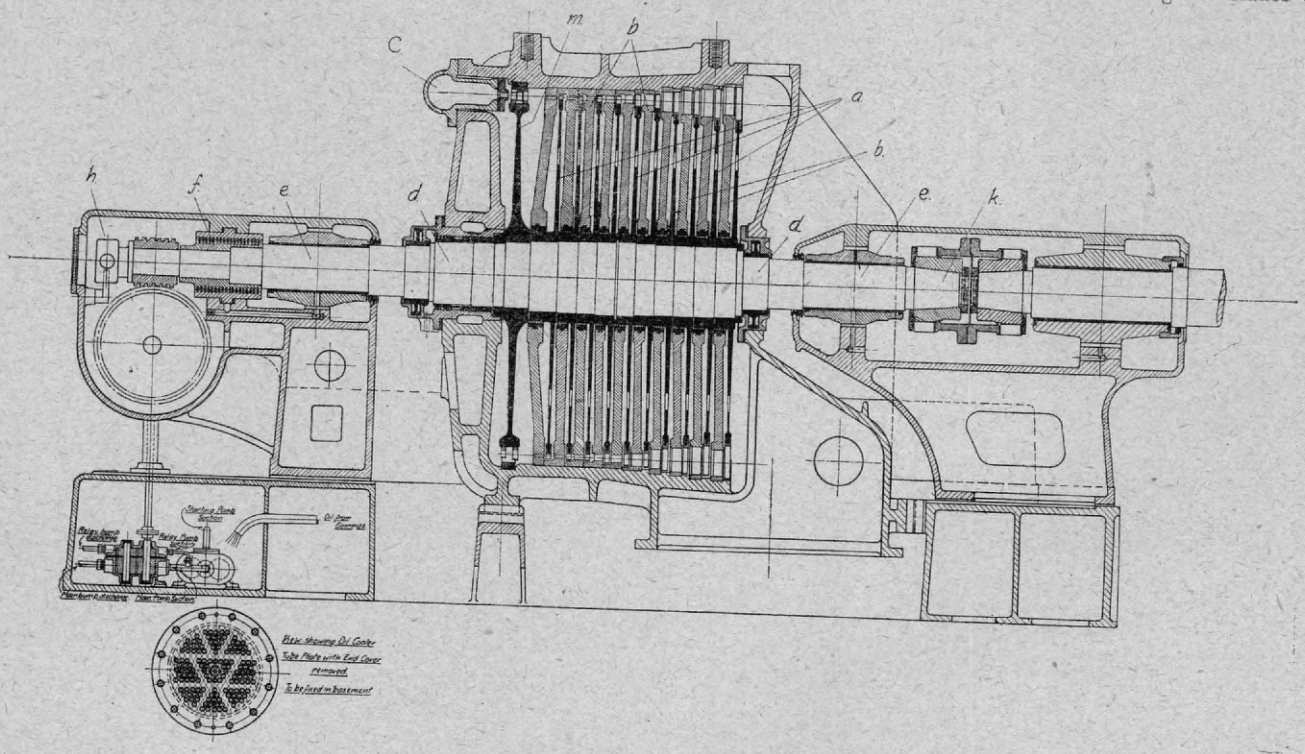
THE WESTINGHOUSE IMPULSE TURBINE

IT is now well known that after investigating fully various designs of steam turbine, the British Westinghouse Co. have adopted the impulse turbine as their standard machine, and manufacture these under the Rateau Patents. The Company have issued a handsome descriptive book relating to these turbines, from which it is of interest to take a few particulars.



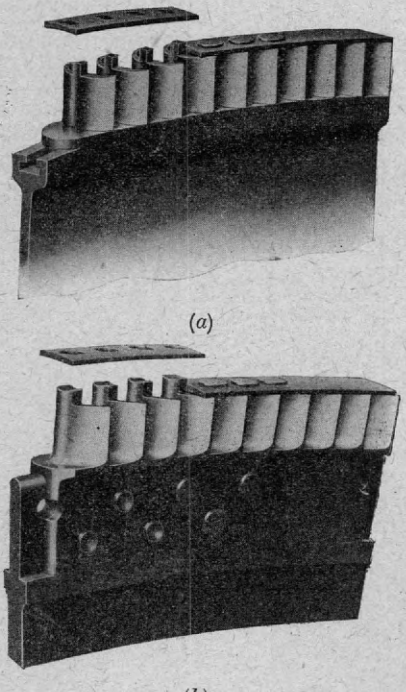


FIG. 1.—LONGITUDINAL SECTION OF WESTINGHOUSE IMPULSE STEAM TURBINE.

Fig. 1 gives a section of a high-pressure impulse turbine as made by the Company. The discs carrying the moving blades are shown at (*aa*), and the diaphragm with fixed blades or nozzles at (*bb*). The nozzle blocks through which the steam first expands are shown at (*c*). These are generally three in number; one will take up to half load, two up to full load, and the third is for overload or running non-condensing. Two of these nozzle blocks are generally arranged in such a manner that they may be cut out if desired when running on small loads for a long time. Special glands (*dd*) are provided at each end of the cylinder.

The bearings (*ee*) are separated from the glands by small isolating chambers, which separate the cylinder from the bearing-housings and casings in which the parts requiring lubrication are situated and which are best kept cool. To maintain the spindle in its correct relative position with the cylinder, a registering block (*f*) is provided. Next to this on the spindle is a worm driving a worm wheel, which in turn drives the main governor. On the extreme end of the spindle is the safety governor (*h*). At the other end of the spindle is the flexible coupling (*k*). The oil pump, driven by a vertical shaft through bevel gears from the main governor shaft, is placed in the oil tank at the end of the bed-plate. This pump delivers the oil under pressure to the cooler, from whence it is forced to the various bearings. After passing through the bearings it flows back by gravity to the oil tank, so completing the cycle. A small auxiliary oil pump is also fitted for starting up.

The diaphragms are arranged in such a manner that the respective halves in cylinder cover and lower half are not disturbed when the cover is lifted. The outer periphery fits in a groove in the cylinder, and the inner periphery is provided with special glands, which almost touch the shaft, and are of such a nature and design that if touching takes place between them they wear their own clearance without causing any trouble. The nozzles, or guide-blades, are made of a special steel, and are cast into the cast-iron diaphragms by a special process.

The blade wheels taper in thickness from the centre to the periphery, where the thickness is again increased and formed to take the blades. Each wheel, machined all over, is provided with large balance holes to ensure the pressure at each side always being the same. Each blade is machined out of the solid bar, each curve being given by a former or matrix fixed to the machine. Two methods of fixing the blades to the wheels are adopted. These are illustrated as (*a*) and (*b*) (Fig. 2). The "straddle" formation (*b*) is secured by means of rivets (in double shear), while (*a*) is a dovetail, the portion

(*a*)

(*b*)

FIG. 2.—ALTERNATIVE METHODS OF ATTACHING BLADING.

of the blade accurately fitting the groove formed in the periphery of the wheel, which is provided with two "ports" to allow of the blades being put into position. Each blade is finely finished and polished, to reduce skin friction to a minimum. The clearance between the blades and stationary

Hosted by Google

parts varies from $\frac{1}{8}$ inch in the smaller to $\frac{3}{16}$ inch in the larger sizes.

The main governor is enclosed and is of substantial design, and a separate over-speed safety device is also provided.

The low-pressure, exhaust, and mixed-pressure turbines are similar in principle, but, of course, different in proportion, and the Company make a speciality of back-pressure and reducing turbines suitable for those working conditions where steam, at a pressure which cannot be described as either boiler or exhaust pressure, is used for some process in manufacturing, and where, at the same time, electrical energy is required. Large savings can be effected with these turbines in paper mills, dye and bleach works, chemical works, sugar refineries, laundries, distilleries, and large public institutions, such as hospitals, workhouses, and asylums, where steam is required for heating the buildings.

A good example of the most recent design of Westinghouse turbine is that driving the new 1,000-kw. set just installed in the St. Helens Electricity Works. This drives a 6,000-volt alternator at 3,000 r.p.m., and takes steam at 160 lbs. per sq. in. The steam consumption guaranteed by the manufacturers when they obtained the order was 15·9 lbs. of steam per kilowatt hour at full load; the actual consumption, however, which was obtained when the machine was tested came out at 15·64 lbs. per kilowatt hour, which is 1·6 per cent. better than the guarantee. The condenser is of the low-level jet type, manufactured by Mirrlees Watson, Glasgow, with Westinghouse motors driving the various pumps. Up to the installation of the 1,000-kw. turbo-alternator, the whole of the alternating current generated was supplied by two Westinghouse rotary converter equipments of 250 and 550 kw. respectively. Each of the rotaries is designed specially to be reversible, that is to say, they can convert direct-current into polyphase alternating-current, or *vice versa*. Now that the turbo set is installed, these rotary converters will form a very flexible and most efficient link between the direct-current and alternating-current systems of supply.

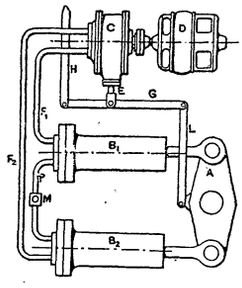
AN ELECTRO-HYDRAULIC STEERING GEAR

A PAPER by Dr. H. S. Hele-Shaw, F.R.S., and Mr. F. L. Martineau, read on April 7th before the Institute of Naval Architects, describes a form of electrically driven steering gear with a new form of hydraulic transmission, the first example of which has been installed on the steam-turbine yacht *Albion* (1,700 tons displacement), belonging to Mr. H. Loeffler. The gear is alternative to ordinary steam steering gear, but has been used practically exclusively since its installation.

Fig. 1 is a diagrammatic view of the gear. The rudder-head, *A*, is operated by rams, working in two cylinders, *B* 1 and *B* 2. The rams themselves are actuated by oil, which is supplied from a Hele-Shaw rotary variable stroke pump, *C*. The pump itself, which we describe in more detail below, is driven by a shunt-wound electric motor, *D*, which is kept continuously running whenever the boat is under weigh. The action of the gear is as follows: *E* is a rod controlling the effect of the pump in such a way that when it is in mid-position no oil is being pumped. According as it is moved in or out from the central position the oil is transmitted under pressure to the cylinders *B* 1 and *B* 2. In this way, by the mere movement of the spindle *E* the rudder-head can be put over to port or starboard as required. The actual operation of the spindle *E* is effected by means of a floating lever, *G*, coupled near its middle point to the spindle *E*, and controlled at one end by a lever, *H*, which is connected with the telemotor, and operated from the bridge. The other end of the floating lever *G* is connected, by means of the link *L*, to the tiller-head. Thus, as the link *H* is moved, the other end of the lever *G* being for the moment fixed, the spindle *E* starts the pump in operation, and as a consequence the tiller-head begins to move. In doing this, the link *L* moves the other end of the lever *G*, and hence tends to bring the spindle *E* to its middle position, and so stops the pumping action (although the pump continues rotating), and in doing so the rudder-head is left exactly in the position corresponding to that which the wheel and telemotor have been made to take up. The only other essential feature is the pipe *P* connecting the two ram cylinders, in which is placed a spring-loaded by-pass valve, *M*, so arranged that, if the rudder be subjected to any shock which would bring about more than certain predetermined stresses, the rudder-head is able to yield by the transfer of oil from one ram cylinder to the other, and, since the floating link is thereby moved, the pump is automatically set in operation and the rudder restored to the position corresponding to that of the steering wheel (without the intervention of the steersman).

The principle of the variable stroke pump is shown in fig. 2. It is direct coupled to the motor, and its construction is such that it can run at very high speeds with a good efficiency for a large range of pressures. The pump consists of four parts—namely, the containing case, carrying the bearings in which the rotating portion works; the revolving cylinder body, in which the working rams operate; a central fixed shaft, in which are the induction and eduction passages, *P* and *Q*, lengthways, and which acts as a fixed valve in communication with the various cylinders; and the guide ring, a circular frame capable of being moved to and fro by the spindle *E*, so that it can either be placed in the central position, as shown in the first diagram, or moved to and fro on either side of centre as shown in the second and third diagrams.

Suppose the guide ring to be in the central position, and



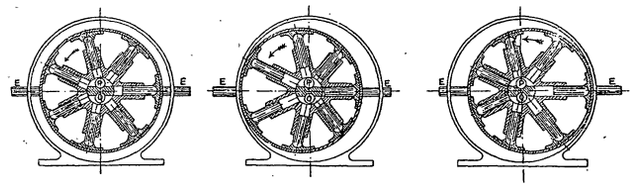


Fig. 1.—Diagram showing General Arrangement of Electro-Hydraulic Steering Gear.

the cylinder body rotating in the direction shown by the arrows, then, inasmuch as the slippers rotate in a circle, no movement of the plungers takes place, and there is no suction or delivery. This is the usual condition of affairs when the helm is steady. Suppose now a movement of the wheel is made; the telemotor moves the guide ring in one direction or the other, according as the helm is put over to port or starboard. Let us suppose, in the first place, it is put over in the direction of the second diagram. In this case the plungers moving above the centre line will evidently be moving outwards, and, therefore, will be drawing oil along the passage *P*; and, having reached the extreme outward position on the left, they are in turn closed by passing the

Middle position. No discharge.

Full stroke. *P*, suction. *Q*, delivery.

Full stroke, reverse. *P*, delivery. *Q*, suction.

Fig. 2.—Sketches showing Principle of Variable Stroke Pump.

shaded portion of the bridge, and on passing through the lower half of the circle are gradually forced inwards, the oil contained in them being driven along the passage *Q* shown in cross-section, and, finally, when empty, are closed by passing over the bridge on the right-hand side. Thus *P* becomes the induction and *Q* the eduction passage, and the oil in the ram cylinder to which these parts are respectively connected becomes greater or less, and causes corresponding movement of the ram. The reverse operation takes place if the guide ring is moved by the spindle *E* to the position in the third diagram, when *Q* becomes the induction and *P* the eduction passage. In actual use the full-stroke position is rarely reached.

The gear is being fitted on the Orient s.s. *Orama* and on two new Austrian Lloyd steamers. The Paper describes a long range of experiments which were made on the gear on board the *Albion*. A special lag recorder was devised to show the relative movement of the telemotor and the rudder-head at any instant. This showed that the rudder in the case of the electro-hydraulic gear followed the wheel much quicker than with the steam steering gear in action, and this confirms the opinion of the captain of the superior working of the new gear. Results of power and efficiency movements are also given, from which it would appear that a 3-h.p. motor would have been quite sufficient for the work, instead of the 10-h.p. machine used.

PUBLIC ELECTRICITY SUPPLY IN COUNTRY DISTRICTS

THE above was the title of a Paper by Mr. B. Woodhouse (Chief Engineer, Yorkshire Electric Power Co.) read on Wednesday of last week before the Yorkshire Section of the Institution of Electrical Engineers at Leeds. In his introductory remarks the author referred to the rapid advances electric lighting and power had made, and sketched the influence of the various Acts of Parliament dealing with the matter from time to time up to the Power Acts of 1901 and 1902, under which his own Company had its powers. He referred to the opposition to large power schemes which had often been offered by local authorities, and the serious restriction which had been imposed in many cases in consequence. Despite these restrictions, however, a number of power companies have developed their supply in such a manner that the cost of electric power in the last ten years has been more than halved, and a public supply has been made available for purposes formerly undreamt of. At the time the Power Acts were passed many small boroughs, &c., had taken out provisional orders, and some were running supply systems too small to be economical; but there was now a greater tendency towards supply on a large scale. Thus, in Yorkshire, when the Power Company started operations in 1905, there were twenty-five districts in which the local authorities had taken out electric light orders.

Of these orders, twelve have been revoked by the Board of Trade, seven transferred to a company taking a bulk supply, and four put into force by the local authorities taking a bulk supply from the Power Company. In not a single case has a small generating station been erected.

Mr. Woodhouse then went into figures to show how the size of the undertaking affected the costs, and said that cost of production in a 10,000-h.p. station was less than one-third that in a small station, and there is the additional advantage of a better load factor owing to greater variety in the nature of the load.

Passing on to the question of distribution, Mr. Woodhouse said that an analysis of the results of supplying electric light by means of underground mains in a number of small undertakings showed that for lighting alone there is a yearly sale of ten units of electricity for every £ of capital spent in mains. In other words, to obtain 8½ per cent. return on the capital, a profit of 2d. per unit must be earned. It was clear, then, that any reduction in the cost of distributing mains would have an important effect on the cost of electricity.

In agricultural districts electricity supply can only be given at a cheap rate by the use of overhead mains, as the cost of underground cables becomes prohibitive where the houses, farms, &c., are scattered. Estimates are worked out to that in a case with forty services and thirty-six street lamps per mile, with a special switching wire for the public lighting; the main, services, lamps, &c., with a wood pole line would be £440 per mile, as against £760 for underground mains. The author considers that objections on the score of danger and unsightliness of overhead mains have been much exaggerated. Their use, however, is much extending, and on the Yorkshire Company's system over ninety miles are already in use. In Leeds low-pressure overhead wires are in use for street lighting; in Barnsley overhead work of very neat design has been employed in a recent street-lighting extension; and in Honley both street and private lighting is carried out by overhead wires; in Whitwood the same plan is being adopted. At Horseforth the street lighting is carried out by the Yorkshire Electric Power Co. at £2 per lamp per annum, including provision of cables, conversion of gas-lamps, lighting, cleaning, and extinguishing. Street lighting is also being supplied in Mirfield and Whitwood, and the following figures are typical of the cost: Lantern with one 35-watt lamp, lighted 2,000 hours per year; current at 1½d. per unit, 8s. 9d.; cleaning and lamp renewals, 5s. 6d.; maintenance, 1s. 3d.; interest (6 per cent.) on expenditure, 5s. 9d.; total, 21s. 3d. With two 35-watt lamps per lantern the cost came out at 32s. 6d. per post.

Considerable advance is being made in the use of electricity on farms. Power is obtained from motors mounted on waggons taking current from any convenient point on an overhead line, and lighting for the buildings is taken from the same wires.

In a number of cases the Power Company's supply has been used for cottage lighting, an inclusive charge per week being made for the supply of current and lamps, there being no restriction on the hours of lighting. In one such case a group of fourteen cottages is supplied, each cottage being lighted by two 60-watt lamps and two 120-watt lamps. The annual consumption of current per cottage is 160 units. The current consumption is very large on account of the use of carbon lamps. The same illumination from metal lamps would reduce the consumption to 54 units per annum, or 18s. per annum at 4d. per unit. In another case a group of twelve cottages are lighted each by three 16-c.p. tantalum lamps at an annual cost of 15s. 1d. Six other cottages, each lighted with four 60-watt lamps, use an average of 78 units per annum, costing 6d. a week at a price of 4d. per unit.

The author also drew attention to the assistance of electricity in mitigating the smoke nuisance, and at the conclusion of the Paper showed a number of slides illustrating the methods in use at the places mentioned above for street lighting, and the way in the supply of groups of cottages the wires were run on insulators on the outside walls and taken in through the woodwork of the window-frames. Views of typical farm installations were also given.

The discussion was opened by Mr. W. Emmott, who had been formerly in favour of municipal supply, but now advised local authorities to make the best terms they could with the power companies.

Mr. A. Lupton (Chairman, Yorkshire Power Co.) spoke a few words emphasising particularly the flexibility of electric power.

Mr. J. W. Hame (City Electrical Engineer, York) remarked that industries would settle not only where rates and taxes were low, but where electric power was cheap. He asked for some further particulars regarding the charges for current in cottages and the method of collection.

Mr. S. D. Schofield (Borough Electrical Engineer, Shipley) agreed that small generating stations and underground mains were prohibitive in scattered areas. Mr. H. Wilson Hartnell also favoured overhead distribution.

Mr. E. A. Barker (Borough Electrical Engineer, Barnsley) gave some further particulars of the street lighting at Barnsley. The electric lighting had come out considerably cheaper than the gas lighting in the borough. Private supply was given from the same mains as the street lighting.

Mr. F. Thursfield looked forward to extended adoption of electric heating with the cheapening of supply. Small concerns had often disadvantages in lack of capital. The author had said that the revenue rarely exceeded 15 per cent. of the capital expenditure, but on looking the matter up he thought that 23 per cent. was nearer the mark. He also thought that in his estimate of a yearly sale of only 10 units per £ expended on mains, and the subsequent figures depending on this, that the author had been unduly pessimistic as regards the small undertaking. At Chester he had found it impossible to bring the cost of street lighting below £3 per lamp per annum. He thought Mr. Woodhouse's figure of 2,000 lighting hours per year was too low.

Mr. H. H. Wright (Messrs. Wright & Wood) gave some particulars of a windmill electrical plant, but stated that if the Yorkshire Electric Co.'s supply had then been available it probably would not have been erected.

Mr. Holliday (East Ardsley) spoke in favour of overhead mains.

Mr. I. F. Fawcett (Messrs. Loxley & Co.) asked where the critical point was reached when the cost of running mains to a farm would be more expensive than putting down independent plant.

Mr. A. M. Sillar (Yorkshire Electric Power Co.) also asked some questions, and

Mr. H. Dickinson (Chief Electrical Engineer, Leeds Corporation), referred to the saving effected in capital cost by having combined tramway and lighting stations.

Mr. Woodhouse, in reply, remarked that in the Tyneside district, where something like 95 per cent. of the power used was electrical, there had been a very noticeable effect on the smoke nuisance. In reply to Mr. Hame, he would favour a fixed charge for cottage lighting included in the rent. The 2,000 hours objected to by Mr. Thursfield was not a fixed figure, but even at 4,000 hours the cost would not be much increased. With regard to the cost of overhead mains to farms, these were usually carried across fields, &c., which could be done very cheaply, so that independent plant would rarely be cheaper. In reply to one of Mr. Sillar's questions, he quite favoured arrangements whereby power mains and telephone lines could be run on the same poles.

Blackpool Fatality.—On April 10th, T. G. Sidney, an employee of the Blackpool Electricity Works, was killed by shock from a 2,000-volt street lighting main upon which he was working. It appears that certain extensions were being made, and that it was expected that the work would be completed before the time for switching on, and no notice was given to the works to keep the mains dead. The work took longer than was expected, and Sidney received the full pressure to earth. The foreman on the job gave evidence to the effect that he warned Sidney and advised him to use rubber gloves after he had complained of a slight shock, but that he had taken no notice.

SPEED INDICATORS FOR TRAMCARS

THE Tramways and Light Railways Association's Journal for April contains a Report on "Speed Indicators," drawn up at the suggestion of the Board of Trade. The Members of the Special Committee signing the Report are the following:—A. H. Pott (Chief Engineer, Metropolitan Electric Tramways), *Chairman*; R. W. Cramp (General Manager, Birmingham and Midland Tramways Joint Committee), H. England (General Manager, Wakefield and District Light Railways Co.), W. E. Ireland (Rolling Stock Superintendent, L.C.C. Tramways), C. W. Mallins (General Manager, Liverpool Corporation Tramways), and S. Sellon. Full reports of tests of a large number of instruments are included, and the Committee finally came to the following conclusions:—

That there are now speed indicators on the market which, as far as the instruments themselves are concerned, have worked satisfactorily during the tests, although it is not at present possible to state what their life is likely to be when fixed on tramcars. That transmission gears could be made which might stand for some time the rough conditions met with underneath a tramcar; their first cost and maintenance, however, must be considerable. That in view of the first cost and the cost of maintenance of instruments and transmission gear, it would be a serious burden on tramway undertakings to have to equip service cars with indicators. That as the proper maintenance of the existing equipment on a car already fully occupies the attention of the staff during the short time available between cars leaving and returning to the sheds, it is most undesirable to add anything more to a car which will require attention, especially if this is not a vital part of the equipment. That the electrical form of speed indicator is the cheapest and easiest to fit, but from the tests it will be seen that indicators of this type appear unable to stand the rough conditions of tramway operation. That if speed indicators are required at all, they should only be fitted on cars for instruction and test purposes. That except for special test purposes, no speed recording chart is necessary, and a mileage recorder is not required. That no indicator showing the maximum speed attained (by ringing a bell or moving a maximum pointer) is of much value, as the authorised speed varies at different parts of the same route: and whereas it may be safe to exceed an authorised speed of say 16 miles per hour on one part of a route, it may be dangerous on another part of the same route to exceed even four miles per hour. That since the most successful form of transmission gear is that in which a belt or chain is driven from one of the car axles, the wear of the wheel will necessitate a constant adjustment of the instrument, otherwise there would be a considerable inaccuracy in the reading of the indicator.

CABLE LAYING AND JOINTING

MR. C. VERNIER'S Paper on "The Laying and Maintenance of Transmission Cables," which was discussed before the Institution of Electrical Engineers on March 9th, and also at Newcastle (see ELECTRICAL ENGINEERING, March 16th, page 135, and March 23rd, page 151), was further discussed at Newcastle on March 20th.

Mr. P. V. HUNTER reopened the discussion. He considered that so far as external damage and pressure surges were concerned, the solid and armoured systems might be considered as equal, but for resisting chemical action, subsidence, over-running, and vibration the armoured type was superior. The original type of jute sheath was unsatisfactory as it would not absorb heavy bitumen, but the bitumen and tape protection used in the north-east coast districts was highly satisfactory. The fact that their generators gave practically pure sine waves probably accounted for the immunity from breakdown when cables were switched in without the intervention of charging gear. Another point was that the higher the working voltage of the cable, the lower the capacity per mile. Cable insulation breakdowns were largely due to heating by dielectric hysteresis, and this explained why high pressure surges of extremely short duration did not break down a cable, there being no time for the dielectric to reach a dangerous temperature. Experience in this district had shown that there was nothing to fear from creosoted troughing. He pointed out that coal gas had a very serious action on bitumen, and further that air affected vulcanised bitumen.

Mr. E. FAWSSETT confirmed that cables could safely be run at very high densities if excessive voltage drop is not objected to.

Prof. W. M. THORNTON explained how a cable could break down at a point some distance from the place where a surge originated. A cable broke down in exactly the same way as any other condenser.

Mr. G. B. BURROWS showed a design of a cast-iron oil-filled joint box into which the cable ends were led and joined by flexible braids, which he had used on cables liable to breaks due to subsidences and overrunning.

Mr. H. W. CLOTHIER (Messrs. A. Reyrolle & Co.) pointed out that cable-charging devices were still sometimes specified, but they tended towards complication of the switchgear. Surges might be caused by the clearing of short circuits on other feeders, and in this case the charging devices were, of course, inoperative. They were, however, useful in preventing current rushes when switching in open circuited transformers.

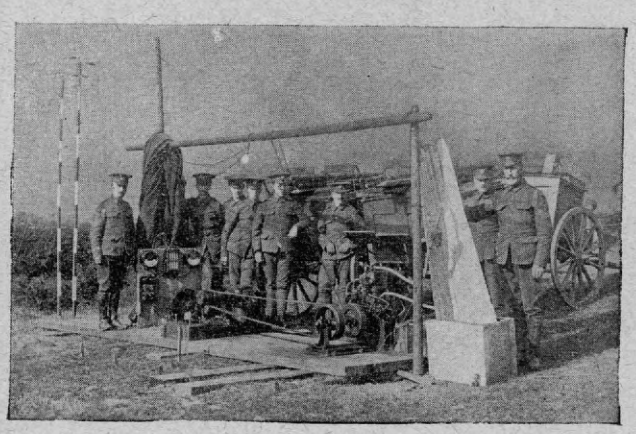
Mr. H. BRIDGES said that in designing manholes the fact that cables had to be drawn in seemed often to be overlooked. A straight pull should always be arranged for, and corners avoided as far as possible. He advocated the use of coffin-shaped manholes.

Mr. G. B. ADDISON advocated the solid system, with earthenware troughs, porcelain bridges, and pitch of the correct proportions, and suggested that faults on armoured cables were more difficult to locate.

Mr. T. H. HARRIS said that his firm was at present laying a cable having a bitumen covering, which adhered to the lead, and the best protection was a well-creosoted board. He thought that the proposal to run cables at 150° F. would lead to trouble.

Mr. G. L. PORTER advised care in the selection of testing apparatus, as he had found that choking coils sometimes altered the wave shape considerably.

Mr. J. E. DAWSON pointed out in a communication that it was not always necessary or advisable to spend money in elaborately bonding ordinary L.T. cables. His own practice was to break the continuity of the lead and armour at every joint box, as he considered that by bonding everything up solid one was simply providing a return circuit which competed with the earth and water mains. The distribution system at West Hartlepool was installed on these lines over twelve years ago, and no more than the usual trouble due to earth currents had been experienced.



Mr. W. HOGG (communicated) advocated the use of armoured cables laid solid where passing through made-up ground. He described an expansion joint which he had used in India.

Mr. C. BEAVER (communicated) suggested that breakdowns due to cable movement usually occurred close to joint boxes—*i.e.*, at the point when the cable was held rigidly—and he advocated looping the cable at each side of the joint. To ensure that boxes are completely filled with compound, he favoured the use of a funnel for filling, making sure that a head of compound was maintained in the funnel at a higher temperature than that in the box.

Mr. C. VERNIER replied briefly.

OSRAM LAMPS IN CAMP

THE General Electric Co. have sent us the accompanying illustration, showing the use of Osram lamps at the Bexhill summer camp of the Royal Engineers. The plant comprised a portable 4 h.p. petrol dynamo, complete with battery. This equipment was used in the day-time to charge the cells for wireless service, and at night provided current for groups of Osram

lamps in the officers' mess, sergeants' mess, orderly tent, mess canteens, &c. Overhead lines attached to service poles were used for the distributors. The average distance of the lamps from the plant is 300 yards, and they are run on a 50-58-volt circuit. The interior of the waggons carrying the wireless apparatus was lighted by Osram motor-car lamps.

Rubber and Allied Trades Exhibition.—The International Rubber and Allied Trades Exhibition, to be held at the Royal Agricultural Hall from Monday, June 26th, to Friday, July 14th, at which a number of foreign Governments will be represented, will contain exhibits of varying nature relating to the production and preparation of rubber, rubber machinery, &c. Not the least interesting feature will be the display, for the first time, of commercial synthetic rubber, and the opportunity of comparing this product with natural rubber will be afforded.

CORRESPONDENCE

ELECTRICITY METERS.

To the Editor of Electrical Engineering.

Sir,—With regard to the paper recently read at the Institution on Electricity Meters, I am inclined to agree with those gentlemen who, in the discussion, disapproved of the criticisms passed on the mercury motor meter. The fact that the sale of this type represents a huge majority of meter sales alone proved that it is a very good and useful article. The statement that it is difficult to obtain sufficiently high driving torque as the current capacity is reduced is not correct, in my experience during the past few years, which, on the contrary, shows a 1½-ampere meter registers well within the limits of an 8 c.p. lamp, and beyond this it is surely unnecessary to go under present commercial conditions. Further, the curve obtained is good. The principal disadvantage of the mercury motor meter appears to be its tendency to amalgamate, but in cases where the armature is properly and carefully protected, such amalgamation goes on at a very slow rate, if at all; with the exception of meters which are constantly much overloaded, the error from this source rarely exceeds 3 per cent. within a reasonable period of overhauling. This is assuming, of course, that the meter was originally provided with clean and pure mercury. Enamelled discs are now being made, and, so far, appear to get over the difficulty; but even if this new introduction is not entirely successful, it must still be remembered that cases are comparatively common where the fibre-covered discs of the old type Hookham meters have been out on circuit for ten to twelve years without suffering from such troubles at all. As regards electrolysis taking place in the bath, this is practically limited to cases where the meters have been severely overloaded, and the baths thus unduly heated. This is also probably the cause, partly, of many amalgamation troubles.

As regards commutator ampere hour meters, beyond the fact that they are cheap there is nothing in their favour, and even their cheapness is more than overbalanced by their unreliability and the expense and difficulty of repairing them. Their fragile nature, construction, and excessive speeds will be found serious drawbacks to their general adoption.

Regarding the dynamometer type watt hour meter, it is possible that, if sold cheaply enough and well constructed, a meter on this principle will have a fair chance; yet it remains that its only advantage over any other good ampere hour meter is that it registers correctly fluctuations of the voltage, and in any well-regulated system this should not amount to more than 2 per cent., if that, and even in cases where the supply voltage is known to be above the declared voltage the meters could be left 1½ per cent. or 2 per cent. on the fast side at the higher load, where the greatest loss from this source is considered to take place, and this alteration could be made without in any way departing from the limit of accuracy imposed by the Board of Trade. Further, this type of meter is still subject to trouble with the commutator, bottom bearings, and jewels, and is not so well fitted to withstand weather conditions to which meters are occasionally subjected to on service, as are those of the best ampere-hour type. Further, with regard to watt-hour meters, the shunt loss on a large system becomes an important consideration, especially under the conditions produced by large tenement buildings having a number of separate consumers with a comparatively small load.

With reference to electrolytic meters, if one excepts the small hermetically sealed production of Messrs. Reason—which is to be found very good on the smallest jobs—their advantages are not easily seen, whereas their disadvantages are very considerable, and, from the commercial point of view of the meter department, render their use altogether inadvisable.

Aron meters undoubtedly embody the best theoretical design for any meter, and naturally they are by no means cheap in first cost. Further, they are not easy to clean and repair. They require a lengthy test, and are liable to error if out of plumb. They rely on very good insulation, and are still subject to the inevitable shunt loss attached to watt-hour meters.

The old "Elihu Thomson" meter was one of the best revolving armature watt-hour meters of its day, and the advantage of being equally suitable for use on A.-C. or D.-C. circuits was an important factor. Further, it could be overhauled easily, pivot and jewels could be replaced without upsetting any adjustments, but still there were features which unfitted it for present-day use in house services.

As regards A.-C. meters, the induction type is favoured on account of absence of friction and light weight of the armature, and good results are obtained with comparatively small driving torque and corresponding shunt current. Unless the load gives rise to considerable distortion of wave-form, error due to this will not be prohibitive on any well-designed induction meter. The quadrature adjustment mentioned by Mr. Edgecumbe in the discussion is very quickly and simply made, and is surely sufficiently accurate when the power factor does not deviate widely from unity.

Yours faithfully,

H. Richardson,
General Manager.

Electricity Supply Department,
Dundee, April 11th, 1911.

THE PRICES AND LIFE OF OSRAM LAMPS

Considerable reductions in the prices of high candle-power Osram lamps are announced in a circular from the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), and the 100, 200, 400, and 600 c.p. sizes, which are now so much used for street lighting, are now listed at 4s. 9d., 9s., 17s., and 20s. each. The Company in doing this are giving great assistance to central station engineers in encouraging the extended use of the metal filament lamp for street lighting. They have always endeavoured to arrange that the prices of high candle-power lamps should not be unduly above those of small candle-power, but should be strictly in accordance with cost of production. The growing use of the larger lamps now enables the high candle-power lamps to be made in economical quantities, and the cost accurately ascertained. We understand that arc lamps have been recently replaced by Osrams at Torquay, Acton, West Hartlepool, Cardiff, and Hammersmith, and in the last-mentioned district a saving of £2 16s. per lamp has resulted. At Yarmouth both gas and arc lamps have given place to Osrams, and at Wimbledon, in addition to replacing arcs, they are in use for side street lighting. In the stations of the Underground Electric Railways of London metal filament lamps have also replaced some thousands of arcs, and other localities where Osram lamps are in extensive use for public lighting are Kensington, Paddington, St. Marylebone, Kingston, Shoreditch, Croydon, Partick, Nuneaton, Wolverhampton, and Exeter.

Some interesting life tests of these lamps are contained in an extract from the lamp register of the Hammersmith Electricity Department. Of seventy-five lamps, of which particulars are given, only five were alight under 1,000 hours, while the average life was 3,613 hours, the individual figures varying from 793 to 8,480 hours. The sizes of these lamps are not stated, but presumably they are all of high candle-power.

With regard to the life of Osram lamps of smaller size, the company have sent us a copy of part of a report of some life tests carried out at the National Physical Laboratory on six 100-volt Osram lamps. The average c.p. during a 2,000 hour test worked out at 16·0 (British c.p.), and the watts per c.p. at 1·29. One filament broke after 1,990 hours, but the remaining five lamps were intact after the full 2,000 hours.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

"ONEWATT" LAMPS.—A new list announcing reductions in the prices of "Onewatt" lamps of 100, 200, and 300 c.p., and dealing also with "Onewatt" lamps from 20 to 50 volts, is to hand from Siemens Bros. Dynamo Works, Ltd. (Incandescent Lamp and Fittings Department, Tyssen Street, Dalston, N.E.). The list is printed in two colours, and can be overprinted with the name of any contractor. The reduction in price of these lamps is referred to further in our Business Notes.

HOISTS.—A leaflet from the Union Electric Co., Ltd. (Park Street, Southwark, London, S.E.), illustrates and describes several patterns of the "Union" friction hoists, which are especially suitable for use in connection with building construction. They are supplied for both D.C. and A.C. (three-phase) circuits, and various sizes capable of lifting from 5 to 45 cwt. are listed. Motors, gear, and starters are designed to withstand the rough usage unavoidable in building work.

AUTOMATIC STARTERS.—An illustrated leaflet from the British Thomson-Houston Co., Ltd. (83 Cannon Street, London, E.C.), describes a series of starters for non-reversing D.C. motors of 15 h.p. and over, designed primarily for the automatic control of motor-driven pumps, and depending for their operation upon a change in level of liquid or pressure of liquid or air. They consist of a number of contactors and current relays assembled on a slate panel, which, together with the resistances, is attached to a pipe framework.

METERS.—Another leaflet from the British Thomson-Houston Co. contains a list with prices of the various sizes of the B.T.-H. "High-Torque" A.C. watt-hour meter, house-service pattern, for two- and three-phase power circuits. It has two single-phase driving elements acting on a single disc, and special care has been taken to prevent interference between these elements.

SWITCHES.—Two other leaflets from the British Thomson-Houston Co. describe respectively float switches for use in connection with automatic starting rheostats for the control of pump motors, and a gauge-type pressure governor also for use with automatic starters controlling pump motors for maintaining a predetermined air or water pressure.

RADIATOR LAMPS.—Radiator lamps with either Edison screw or Bayonet caps finished to match the finish of the radiator in which they are to be used, and consuming about 250 watts each, are described in another B.T.-H. leaflet.

WINCH.—Another B.T.-H. leaflet describes a small automatic hoisting winch suitable for raising and lowering arc lamps, small machine tools, &c., and adapted for outside use. It is claimed to be absolutely fool-proof.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published April 13th, 1911

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.
Names in italics indicate communicators of inventions from abroad.

3,883/10. **Fuse Carrier.** V. Hope (Manchester). An enclosed replacement fuse has a number of fuse wires in parallel mounted in a fire-proof carrier independent of the enclosing casing. Each wire is in a separate longitudinal cell divided again by partitions into several short cells. Further, another compartment opening into all these different cells, but otherwise closed, serves to cushion the explosive effect. When the fuses have blown, a new carrier can readily be inserted in the holder. Ten figures.

7,656/10. **Long-distance and Wireless Telephony.** C. E. Egner and J. G. Holmstrom (Stockholm). A telephone transmitter for dealing with heavy currents has a vessel containing a cooling liquid attached to it so that the bottom of the vessel is in contact with the chamber containing the granules. The heated liquid rises and thus creates a circulation of the liquid. Another method of cooling the transmitter consists in filling the vessel with paraffin wax or other solid body which is melted by the heat produced. Three figures.

10,065/10. **Candle-lamp Holder.** C. C. Regnart (London). A holder for candle-lamps has a cap screwing on to the back to retain the insulating body, and on this cap are a number of upwardly projecting spring fingers which engage with the interior of the sconce. A threaded ring on the holder expands the fingers against the interior of the sconce when it is screwed down. Three figures.

13,176/10. **Protection of Cables.** M. S. Conner and Peel-Conner Telephone Works, Ltd. This specification describes an apparatus for coating the braiding of telephone and other cables with preservative paint. It consists of a metal vessel containing the compound, and having dies or bushed openings at the bottom below the level of the liquid through which the cable is passed. Compressed air is supplied to the vessel above the liquid to force it into the interstices of the braiding. One figure.

21,310/10. **H.-T. Switchgear.** Siemens Bros. Dynamo Works, Ltd., R. A. R. Bolton, and J. C. Willcocks. This patent covers certain improvements in the construction of oil-switches of the pattern in which the casing containing the movable parts can be slid away from the chamber containing the fixed live contacts. The levers for working the switch and for moving the carriage are separate and independent. It is impossible to move the carriage out far enough to expose the live contacts, nor can the carriage be moved inwards again until the oil tank and lid have been replaced and the switch put in the off position. Six figures.

23,535/10. **Metal Filament Lamps.** G. F. Attwood (Newark, U.S.A.). Metal filaments are particularly susceptible to breakage adjacent to the supports because the rigid connections render them less flexible at these points. According to this invention, the filament is fused to the extremity of the support as usual, but its movement at this point is limited by coiling the filament a few turns round the support. The use of two or more filaments in parallel for low voltage lamps similarly coiled round the supports at their extremities is also covered by this patent. Two figures.

24,122/10. **Telephone Switchboard Cords.** Western Electric Co., Ltd. (*E. Zwietusch & Co., Berlin*). To protect telephone switchboard cords at the point near the plug, the cord is enclosed in a sheathing consisting of a number of interlocking rings, the adjacent members of which slide one within the other. The sheath also prevents the cord having too sharp a bend. One figure.

24,549/10. **Metal Filament Lamps.** F. Skaupy (Berlin). In order to reduce disintegration of the filament and consequent blackening of the bulb, the stem of the filament carrier is made hollow, and contains a small quantity of a halogen compound, the gas from which tends to prevent the disintegration. The hollow stem is in communication with an open sphere or bulb at the free end of the stem, and any deposit from the halogen compound is retained in this. Five figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.
Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: Kamm [Cinematograph projectors] 7,815/10.

Distribution Systems, Cables and Wires, Insulating Materials, &c.: Siemens Bros. & Co. and Dieselhorst [Electrical conductors] 13,672/10.

Dynamos, Motors, and Transformers: Lake (*Weston Electrical Instrument Co.*) [Synchronising of alternators] 13,336/10; Milch [Control of induction motors] 23,958/10.

Electric Ignition: R. Bosch, 22,580/10; Macquaire [Sparking plugs] 23,577/10; Goodhart, 219/11.

Electrochemistry and Electrometallurgy: Electrochemische Werke Ges. [Improving mechanical and electrical properties of copper] 7,657/10; Weber and Schmidt [Zinc-carbon primary cell] 10,561/10; Thomson [Electric furnaces] 15,164/10 and 15,165/10; Langbein-Pfanhauser-Werke A.-G. [Manufacture of ductile electrolytic iron] 25,969/10.

Incandescent Lamps: Pakenham and "Z" Electric Lamp Manufacturing Co. [Machines for making lamps] 12,754/10; Harrison [Exhaustion of electric lamp bulbs] 10,870/10.

Instruments and Meters: Burstyn [Electrical condensers] 11,787/10; Perman [Speed-recording apparatus] 24,482/10; Lowne [Indicator of revolutions expressed in money-value at a rate per unit adapted to be varied] 29,692/10.

Storage Batteries: Pritchett [Boxes for accumulators] 15,425/10.

Switchgear, Fuses, and Fittings: Adams Manufacturing Co. (*Cutler Hammer Manufacturing Co.*) [Electrically-controlled pressure-regulating devices] 7,428/10; Clarke, Chapman & Co. and Harris [Resistances] 12,428/10.

Telephony and Telegraphy: Neuhold [Automatic telephone systems] 7,659/10; Egner and Holmstrom [Cooling of telephone transmitters] 8,019/10; Burney and Bell [Intercommunication telephones] 18,180/10; Gottschalk [Telephone instruments] 28,396/10.

Traction: Samaia [Actuating conduit covers of slot conduit tramways] 8,862/10.

Miscellaneous: Rausch [Electric time signalling apparatus] 12,316/10; Custance and Miller [Galvanic socks and other articles of clothing] 14,739/10; Bailey [Scenery-raising gear] 26,503/10; Baker and Longstreth's, Ltd. [Means for projecting a beam of light through relatively opaque atmosphere] 30,298/10.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Electric Ignition: Reno and Bois [Distributor] 21,949/10.

Switchgear, &c.: Fuss [Voltage regulators] 7,220/11.

Traction: Bacon [Rail-joints] 2,027/11; Balachowsky and Caire [Electric vehicles] 7,062/11.

The following amended Specification can now be obtained.

British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Protective devices for transformers] 13,276/04; H. Leitner [Train-lighting dynamo] 8,219/10.

Opposition to Grant of Patent

16,076/09. **Metal Filament Lamps.** Pope's Electric Lamp Co., Ltd. (*C. Trenzen*). This patent has been granted in spite of opposition. It covers a method of joining metal filaments to their leading-in wires, and was abstracted in Electrical Engineering, Sept. 29th, 1910.

Amendment

18,036/09. **Circuit-breaker.** S. Jevons and V. D. Green. Certain corrections have been made in this specification. It describes a circuit-breaker for electric welding apparatus, which is opened by de-energising a relay-magnet or solenoid energised from a source other than that of the welding transformer.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

10,353 of April 26th, 1897. **Rail Sanding Apparatus.** J. and H. E. Gresham. This patent covers a device for discharging sand between the rails and wheels of vehicles by compressed air.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: J. Rosemeyer [Clutch mechanism] 28,628/04.

Dynamos, &c.: Siemens Bros. & Co. (*Siemens-Schuckert Werke*) [Single-phase motors] 29,435/04 and 29,436/04.

Incandescent Lamps: E. Bohm [Lamp bulbs blown with spiral corrugations] 26,746/01.

Switchgear, &c.: M. B. Field and Ferranti, Ltd. [Fuses] 29,377/04.

Telephony, &c.: Siemens Bros. & Co. (*Siemens & Halske A. G.*) [Telephone exchange system] 28,455/04.

Traction: E. Tyer [Electrically-operated points and signals] 27,607/98.

Miscellaneous: F. W. Hurd [Coal-cutters] 28,353/04 and 28,647/04.

Hosted by Google

THE MECHANICAL DESIGN OF INDUCTION MOTORS

A PAPER on the above subject by Mr. H. L. Smith was read on March 30th before the Rugby Engineering Society. The author discussed the various parts of such machines in the order that they have to be put in hand in practice, and, commencing with dies, gave notes on the graduation of a series of slot dies and the dies for the punchings themselves. The die for the central hole should be separate from that for the axial vents, and the diameters of the various sizes of stators and rotors should be arranged in regular sequence like a genealogical tree, so that the same die which is used for the gap of a large machine can be used for the outside diameter of a small one, the gap in the stator being the even dimension, and the allowance for air gap being put on by circular-shearing the rotor coreplates.

Considering next the stator frames, &c., the author laid down the principle that stationary parts should be of cast iron and massive to resist vibration, and that moving parts should be of wrought iron or steel and light. End shields should be cast iron with the ends flat, and not oblate cones. The stator flanges should be ordinary and not malleable cast iron. The rotor flanges should be malleable cast iron, or even steel where necessary, and light. The spider, being a part revolving at less peripheral speed than the flanges, can be ordinary cast iron. As regards the important question of cost, it should not be lost sight of that a strong casting is cheaper to machine than a light one, because it can be gripped in the jig more firmly.

In discussing the design of baseplates, the author differentiates between the plain or monolith style of design, ribbed designs of the nature of steel rolled joists and designs of more complicated nature analogous to built up girders. The first calls for more metal, but is cheaper as regards pattern-making and moulding, but more refined designs are often easier to machine without fear of springing. The degree of complication in the design should depend upon the size of the machine, the number required off each pattern, and in special cases upon the destination to which it has to be transported.

An important point to be borne in mind in designing shafts is that, since turning is one of the cheapest of manufacturing operations, and the shaft in point of peripheral speed comes within the slow-moving category, it should be of ample diameter.

It is important that the shafts should fit well in the spiders to take full advantage of their support in lessening deflection. Again, in order to reduce the risk of the portion of the shaft under compression receiving any permanent set during the operation of forcing the shaft into the spider, it is advisable to arrange for the full pressure to come on only at the final forcing of the spider into position.

In speaking of end shields, it is remarked that in the case of explosion-proof motors the ribbed style is necessary, because there the ribs are used to dissipate the heat. Seeing that cast iron is six times as strong in compression as in tension, the ribs should be on the inside and in compression, while the plate should be on the outside and in tension, especially as the heat is conducted away equally well whichever side of the plate the ribs are on. The covers should be designed strong enough to resist 130 lb. per square inch. Under the influence of the explosion, the end shield tends to assume a spherical shape. Those portions of its contour which shroud the stator end-windings, and which are, or should be already, spherical, are in pure tension, and do not need any ribs, while as regards the flat plate which forms the end of the end shield, the ribs should be on the inside and in compression. The flange where the end shield is bolted to the stator frame can be ribbed externally to the spherical portion of the end shield, or it can be made thick enough to stand on its own merits. The straining actions on an explosion-proof end shield are exactly opposite to those on an open type end shield. In the former it is the flat plate at the end which requires special attention, whereas in the latter it is the curved portion round the stator end-windings.

In conclusion, some formulæ are discussed for bearings on belt pulleys, and a method of calculating the strength of binding bands is given.

Railless Electric Traction.—The promoters of the Rotherham, Maltby & District Railless Traction Bill have notified the authorities of the House of Commons that they do not propose to proceed with their scheme this session. The Bill in question was a competing one with another Bill, having the same objects, promoted by the Rotherham Corporation, and is the third scheme of this character to be withdrawn this session.

ACTION AGAINST WILLANS AND ROBINSON

£23,435 Costs and Damages

JUDGMENT was given on Wednesday, April 12th, by Mr. Pollock, Official Referee, in an action brought by Mr. H. Cruse, of the Cruse Controllable Superheater Co., Salford, and Messrs. Ernest Grether & Co. against Messrs. Willans & Robinson, Ltd., Rugby, to recover damages for alleged breach of contract in respect of the manufacture of superheaters.

It appears that Willans & Robinson manufactured superheaters for the plaintiff company to the designs of the latter, who alleged that certain superheaters were defective, and refused payment. Messrs. Willans & Robinson pleaded in defence that if there were any defects they were caused by defective design, and that they were not, therefore, responsible. Further, they counterclaimed for £1,900 to cover the balance of the price of superheaters delivered to the plaintiffs, the price of certain rejected ones, and the cost of dies, &c., made for their manufacture.

Mr. Pollock, in giving judgment, held that the evidence of both parties proved that the superheaters did not fail by reason of faulty design, but entirely through bad work. He therefore found for the plaintiffs, and awarded them £3,535 damages, with costs on the higher scale. The hearing of the case commenced in October last at Manchester, and after a few days was transferred to London. The case has occupied 55 days, and over 60 witnesses were called. It is stated that counsels' fees amounted to £7,000, solicitors' and witnesses' and other costs to £11,500, while shorthand notes and transcripts are said to be responsible for £1,400. Mr. E. Pollock, K.C., and Dr. Atkinson appeared for the plaintiffs, and Mr. Sankey, K.C., and Mr. Stewart for the defendants.

Electric Traction on Main Lines.—A Paper was read by Mr. J. B. Sparks before the Students' Section of the Institution of Electrical Engineers in London on April 12th, containing a record of the present position of electric traction on the main lines of Europe. The Prussian State Railways have decided upon the conversion of 95 miles of double line between Magdeburg, Leipzig, and Halle, and a 16 mile section is already equipped. Some 180 miles of line in Silesia will also shortly be worked electrically. In both cases the single-phase system at 10,000 volts, 15 cycles, has been adopted. The Bavarian and Baden State Railways are both equipping short sections of main line on the same system. In Austria, the State Authorities are introducing electric traction on the single-phase system upon 29 miles of main line track leading into Trieste, and plans have been prepared for 2,750 miles of main line railways. The three-phase system may be employed upon some of these lines, and also upon the lines of the Austrian South Railway Co. A new main line, which will be worked on the single-phase system, is now being constructed to connect the Bavarian and Austrian State systems. In Hungary, main line sections are to be converted at Prague, and the electrical working of the important line from Buda Pesth to Fiume is also under consideration. The Swiss Federal Railways have adopted the single-phase system at 15,000 volts, 15 cycles, and the St. Gothard line will probably be the first to be equipped. A short section of the new Loetschberg tunnel line is already worked electrically on the same system. The equipment of the Simplon line (3,000 volts, 16 cycles, three-phase) will shortly be extended at the Italian end. The 12-mile Giovi tunnel line, near Genoa, equipped on the same system, is practically complete, while the Mont Cenis tunnel line is also being converted to three-phase working. Other main line sections in Italy will shortly be equipped, but not necessarily on the three-phase system. Various proposals for the conversion of lines near Paris are before the French State Railway authorities, who are assisting in the conversion of the belt railway round Paris. The Chemins de fer du Midi are equipping a 70-mile main line section near Toulouse, and it is probable that the 250 miles of line between Bayonne and Toulouse will be working electrically in a few years. The single-phase system at 12,000 volts, 16 cycles, has been adopted by this company. The P.L.M. Co. is carrying out trials on an experimental line with a view of equipping the main line from Cannes to Ventimiglia. The Swedish State Railways will shortly have an 80-mile line in the extreme north working electrically, and plans have been prepared for the whole State system south of Stockholm, aggregating 1,300 miles of route. The system adopted is 15,000 volts, 15 cycles, single-phase. A 30-mile line in Norway is being converted to single-phase working at 10,000 volts, 16 cycles, and the conversion of certain lines in Denmark is under consideration. Short lines in Russia, Spain, and Holland are referred to in the Paper, which concludes with some notes on the possibilities of electrical working on the main lines in this country. Some interesting slides were shown.

Hosted by Google

LOCAL NOTES

Boston (Lincs): *Electric Lighting.*—Mr. C. Pullan, of Bradford, has asked the Council whether they would consider an electric lighting scheme for the borough, and, if not, whether they would oppose the formation of a company.

Darwen: *Power Tariff.*—The General Purposes Committee have decided to supply electric current for power purposes to customers taking not less than 5,000 units per quarter at a flat rate of ¾d. per unit net.

Ealing: *Meter Purchase.*—Reporting upon the recent Local Government Board inquiry, when Mr. Ross Hooper impressed upon the Council the desirability of purchasing meters out of revenue or reserve fund, the Electricity Committee states that they do not feel disposed to accede to this request. The amount in question is £5,000, and the Council have adopted the Committee's report.

East Kent: *Electric Supply.*—An application is to be made to Parliament for the transfer to the East Kent Electric Power Co. of certain powers of the Kent Electric Power Co., which the latter Company obtained in their Power Acts of 1902 and 1906. The area in question is bounded at points at Swalecliffe, the Isle of Thanet, Hythe, Cheriton, Folkestone, Dover, Stone Street, and Canterbury. Under the proposed agreement the East Kent Co. will erect the necessary generating stations.

Golborne: *Electric Lighting.*—The Board of Trade have agreed to defer the revocation of the Council's electric lighting order for twelve months.

Kingswood: *Overhead Wires.*—The Kingswood Electric Supply Co. have asked for the Council's permission to place overhead wires in certain streets, but the Council have refused, so far as these particular streets are concerned.

Motherwell: *Fire.*—A fire occurred at the Council's electricity works last week, doing damage estimated at about £800. Most of the damage occurred in the storerooms, which were stocked with electrical fittings.

Nuneaton: *Tramways.*—On the suggestion of the Mayor, the question of a tramway system has been referred to the Highways Committee for consideration. It appears that inquiries with this object in view have been made by representatives of a company.

Stourport: *Electric Supply.*—The Board of Trade having threatened to revoke the Electric Lighting Provisional Order for this district, which was granted to the Kidderminster-Stourport Electric Tramway Co., the Council have asked that the Order be extended for a further twelve months. The main reason why the Order has not been put into force is that the Council have refused their permission for the Company erecting overhead wires.

Torquay: *Tramway Arbitration Costs.*—The total costs of the arbitration to decide as to whether the Dolter surface contact system should be retained in Torquay, and which resulted in the system being rejected in favour of the trolley system, amounted to £1,399 15s. 6d., of which the tramway company have contributed £500 as agreed.

Watford: *Street Lighting.*—A report has been prepared by the Electrical Engineer providing for the conversion of all the public gas lamps to metal filament lamps during the ensuing twelvemonths.

TENDERS INVITED AND PROSPECTIVE BUSINESS

GENERATING STATIONS, SUB-STATIONS, MAINS, &c.

Aldershot.—Application is to be made to the Local Government Board for sanction to borrow £2,500 for extensions at the electricity works. It is proposed to instal Deisel engine plant.

Altrincham.—A Local Government Board inquiry was held last week concerning a loan of £6,150 for the provision of generating plant.

Barnsley.—An application is to be made to the Local Government Board for sanction to borrow £16,100. Mr. J. F. C. Snell, who is advising the Corporation, is impressed with the great scope in the borough for a considerable increase in the sale of electricity.

Bulgaria.—The date for receiving tenders for an electrical installation at Varna has been extended from May 5th to May 18th. We gave particulars in our last issue.

Dublin.—A Local Government Board inquiry will be held on the 24th inst. concerning an application by the Corporation for a loan of £128,129 for extensions to the electricity works. The opinion is held in some quarters that the rapid growth in the demand for electricity in Dublin necessitates the erection of a new power station rather than further extensions to the Pigeon House Fort Works.

Egham.—The Egham and District Electric Light Co. require two high-speed Diesel oil-engine driven generating sets; switchboard and overhead travelling crane. Consulting Engineers, Messrs. Handcock & Dykes, 1 Victoria Street, London. Specifications from Secretary, 50 Cannon Street, E.C.

Haslingden.—Tenders are invited for the supply and laying of extra high pressure trunk mains, with medium pressure feeders, and the distributer cables. Particulars from Mr. S. J. Watson, Electricity Works, Bury. (See an advertisement on another page.)

London: *St. Pancras.*—The Council invite tenders by May 15th for three-phase high-tension cable. Particulars from the Borough Electrical Engineer.

Fulham.—A 1,500-kw. turbo-alternator and condensing plant is required. Particulars from the Borough Electrical Engineer, and tenders by April 26th.

Lowestoft.—A loan of £3,000 for new mains is to be applied for.

Luton.—Tenders are invited by April 24th for a turbo-generator, condensing plant, and cooling tower. Particulars from Borough Electrical Engineer.

New Zealand.—Plans and specifications are being prepared for the extension of the municipal station at Wanganui.

Sale.—A Local Government Board inquiry was held last week concerning a loan of £5,900 for electric lighting extensions. This sum is required for the erection of a power station for the supply of the district by the Council itself, as the bulk supply agreement with the Trafford Power and Light Supply Co. expires on March 1st, 1912.

Walthamstow.—The Council invite tenders by April 28th for a cooling tower and switchboard extension. Particulars from Borough Electrical Engineer.

WIRING

Bradford.—New church at Thornbury. Architects, Messrs. Austin & Paley, Lancaster.

Canterbury.—The Electric Lighting Committee recommend that electric light should be installed at the workhouse and infirmary.

Croydon.—Electric theatre, High Street, Thornton Heath.

Edinburgh.—New drill hall for Territorial Force Association. Mr. T. E. Turnbull, 33 Gilmore Place.

Eltham.—New Post Office. H.M. Office of Works, Storey's Gate, London, S.W.

Glasgow—Additional weaving sheds in Fordneuk Street, Bridgeton, for Messrs. John Lyle & Co. Architect, Mr. George Simpson.—Children's hospital at Yorkhill. Architects, Messrs. John Burnet & Son.

Leeds.—Extensions to infirmary.

Maidstone.—County Offices. County Architect, 86 Week Street, Maidstone.

Salford.—School in Nashville Street. Architects, Messrs. Woodhouse, Corbett & Dean, 100 King Street, Manchester.

Wakefield.—New West Riding police headquarters and County Hall.

MISCELLANEOUS

Australia.—Tenders are invited by the Deputy Postmaster-General, Melbourne, by May 23rd, for supply of telegraph and telephone material, and by the Deputy Postmaster-General, Sydney, by June 7th, for the supply of 4,052 yards of submarine telephone cable. Copies of specifications may be had at 72 Victoria Street, London.

The City Council of Melbourne invite tenders for the supply of 120 5-ampere 200-volt A.C. watt-hour meters. Particulars from Messrs. McIlwraith, McEacharn & Co., Ltd., Billiter Square Buildings, London, E.C.

New Zealand.—According to the *Board of Trade Journal*, the Hastings Council propose to invite offers from companies for the construction of tramways in the town.

The Palmerston Council is seeking particulars of the Edison tramway batteries in connection with the proposal to construct tramways at a cost of £61,000.

Salford.—Tenders are required for the supply and erection of fire and police alarm street boxes and switchboard. Particulars from Chief Constable, Town Hall. (See an advertisement on another page.)

Spain.—A supply of 50 tons of steel or iron telegraph wire is required by the Direccion General de Correos y Telegrafos, Madrid.

TENDERS RECEIVED AND ACCEPTED

Australia: Sydney.—The contract for 270 1,200 ampere-hour cells, and 270 2,400 ampere-hour cells, for the Darlinghurst and Burwood tramway sub-stations, has been placed with the Chloride Electrical Storage Co., Ltd.

Derby.—The Electricity Committee have accepted the tender of the British Westinghouse Co. for the supply of 17 half-horse-power motors for hiring out to Metalite, Ltd.

Nuneaton.—The Electricity Committee have resolved to give Messrs. Callenders' Cable Construction Co. the refusal of an order to supply cable at a cost of £83, and failing acceptance by this company, to accept the tender of Messrs. Aubert Grenier & Co., at this sum.

Swindon.—The Electricity Committee have accepted the tender of the Electrical Apparatus Co., Ltd., for the supply of a portion of their meter requirements for the current year.

Watford.—The tender of Messrs. Drake & Gorham, Ltd., has been accepted for the alteration of 550 street gas lanterns to take metal filament lamps.

APPOINTMENTS AND PERSONAL NOTES

Mr. T. Buckley, Chief Electrician of the New Zealand Post and Telegraph Department, will shortly visit England to investigate the latest forms of telephone equipment and installations.

The Wolverhampton Electricity Committee require an assistant canvassing engineer. (See an advertisement on another page.)

A young engineer is wanted immediately for the Mining Department of a large Continental electrical works. (See an advertisement on another page.)

A large number of candidates applied for the post of assistant electrical engineer at the Devonport Electricity Works, in succession to W. F. Stamp, who recently resigned. The short list consisted of J. A. Goodall (Devonport), F. V. Jordan (Warrington), F. D. Martin (Middlesborough).

Mr. B. Sankey, Borough Electrical Engineer at Whitehaven, is to be granted a bonus of £50 for his services in connection with the extension of the power-station plant.

MISCELLANEOUS BUSINESS NOTES

Price of Copper.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £56 to £56 10s. per ton (last week, the same).

"Onewatt" Lamps.—Messrs. Siemens Brothers Dynamo Works, Ltd. (Tyssen Street, Dalston, N.E.) inform us that they have reduced the list prices of their well-known "Onewatt" lamps, of 200 c.p. and 400 c.p., and that the prices of these in all voltages are as from the 15th inst., 9s. and 17s. each respectively. They have every expectation that the lower prices will enable contractors to do an even larger trade in these "Onewatt" lamps than previously. We may add that the price of their 100 c.p. lamp remains unchanged at 4s. 6d., and that they have issued a new price list, printed in three colours, containing the above alterations, quantities of which will be forwarded, we understand, printed with contractor's name and address, on receipt of application, accompanied by trade card.

The Metalite Lamp Works.—It is stated that Metalite, Ltd., will shortly open a factory at Derby for the manufacture of the British Metalite lamp. The works which we understand the company have taken at Derby were originally erected for a firm of incandescent gas mantle makers.

Agency.—An Englishman who has resided in Sweden for 15 years desires to represent British manufacturers of electrical plant. The name and address is on file at 73 Basinghall Street, London, E.C.

Plant for Sale.—A quantity of electrical and steam machinery is offered for sale by Elektron, Ltd. (in liquidation), Gothenburg. (See advertisement on another page.)

Change of Address.—The Midland Electric Manufacturing Co., Ltd., Conybere Street, Birmingham, inform us that they are moving to more commodious premises at Stafford Works, Rea Street South, Birmingham.

Liquidations.—Creditors of the Rosario Electric Co., Ltd., are requested to send particulars of their claims not later than May 30th to the liquidator, Mr. E. H. Benthall, 52 Moorgate Street, E.C.

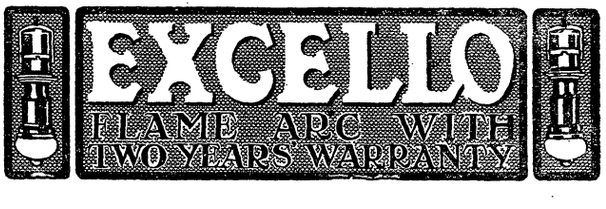
REDUCTION IN PRICES OF HIGH CANDLE-POWER METAL FILAMENT LAMPS

A NUMBER of leading makers and suppliers of metal filament lamps have reduced the prices of lamps of from 100 c.p. upwards. Particulars of these reductions in the case of Osram lamps appear on p. 209, and we understand that among other makers who have reduced or are contemplating a corresponding reduction of price on the same lines are the British Thomson-Houston Co., the Sunbeam Lamp Co., and the Westinghouse Co. Messrs. G. M. Boddy & Co. inform us that they have made similar reductions in prices. An announcement with regard to "Onewatt" lamps appears on this page.

NEW COMPANIES

PERRY & GRISNELL, 1-2 Leopold Street, Birmingham. Capital, £2,000. Manufacturers of electrical, heating, and ventilating appliances.

F. W. VAUGHAN & CO., 22 Cross Street, Islington, London. Capital, £5,000. Electrical engineers and contractors.



C. FENTON LINDOP, 16 Moss Lane, Liverpool. Capital, £2,000. To take over the electrical contracting business now carried on.

GENERAL ELECTRIC COMPANY OF CHINA, 67 Queen Victoria Street, London. Capital, £21,000. To secure the sole representation and agency in the Chinese Empire and Hong Kong of the General Electric Co., Ltd., of London.

ECONOMIC ELECTRIC CO., 17A South Castle Street, Liverpool. Capital, £2,000. To carry on the existing business at the above address.

R.E.T. CONSTRUCTION CO., 56 Moorgate Street, London, E.C. Capital, £52,000. To adopt agreements with the Railless Electric Traction Co., Ltd., and the Railways & General Development Co., Ltd.

L.C.C. Free Studentships at the Imperial College of Science and Technology.—In return for a maintenance grant of £8,000, the London County Council has secured the privilege of nominating twenty-five students for one year's free instruction at the Imperial College, beginning in October, 1911. Only advanced students who are qualified to enter on the fourth year of the course should apply. There is no restriction as to income, but intending candidates must be ordinarily resident in the administrative County of London, and must be students at an institution aided, maintained, or approved by the Council for this purpose, who have attended regularly courses of instruction for at least two sessions. The free studentships do not entitle the holders to any maintenance grants, but cover all ordinary tuition fees. The studentships will be awarded on consideration of the past records of the candidates, the recommendations of their teachers, and the course of study they intend to follow. In special cases the free places may be extended to two or more years. Application forms (T. 2/268) can be obtained from the Education Officer, London County Council, Victoria Embankment, London, W.C., and must be returned not later than Saturday, May 27th, 1911.

Hosted by Google

COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

Kalgoorlie Electric Power & Lighting Co.—The full dividend on the 6 per cent. preference shares for the year to March 31st has been declared.

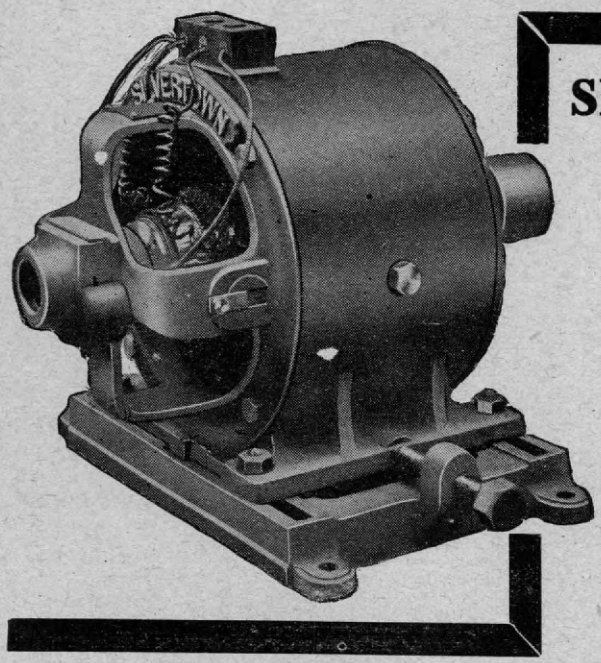
Anglo-Argentine Tramways Co.—At the annual meeting last week Mr. J. B. Concanon called attention to the satisfactory nature of the net revenue for 1910, viz., £868,870. A dividend of 7¾ per cent. for the year has been paid upon the ordinary shares, carrying forward £13,044. An agreement has been come to with the directors of the Buenos Ayres Western Railway Co., which will have the effect of preventing competition between the two companies in the construction of subways for carrying tramways in certain parts of Buenos Ayres.

Kidderminster & District Electric Lighting and Traction Co.—After meeting debenture interest there is a balance of £4,222 for 1910, and after placing £1,175 to depreciation and renewals and meeting preference dividend, a dividend at the rate of 2½ per cent per annum is declared upon the ordinary shares, carrying forward £122.

Kidderminster & Stourport Electric Tramway Co.—There was a net profit of £2,418 for 1910, and a dividend at the rate of 3½ per cent. per annum is declared upon the ordinary shares, carrying forward £166.

Dudley and Stourbridge Electric Traction Co.—After meeting the preference dividend and placing £600 to renewals, the accounts for 1910 show a net profit of £1,060. The directors recommend placing £600 to depreciation, £300 to sinking fund, and carrying forward £160.

Babcock & Wilcox.—The accounts for 1910 show a net profit of £425,443, including £63,083 brought forward. Interim dividends of 3 per cent. and 10 per cent. have been paid upon the preference and ordinary shares respectively, and a further dividend of 3 per cent. is declared upon the preference shares for the December half-year, and 8 per cent. on the ordinary shares, in addition to which a bonus of 8 per cent. is recommended upon the ordinary shares. After meeting these dividends, placing £100,000 to the reserve fund, £25,000 to the dividend equalisation fund, and £10,000 to the staff pension fund, a balance of £68,643 remains to be carried forward.



Wolverhampton District Electric Tramways.—The accounts for 1910 show a credit balance of £659, after placing £100 to renewals fund. It is proposed to place £250 to sinking fund, £250 to depreciation and reserve, and to carry forward £159.

Hindhead & District Electric Light Co.—After adding £755 to depreciation account from the profits for 1910, a final dividend is recommended on the ordinary shares, making 6 per cent. for the year, carrying forward £282.

East London Railway Co.—We understand that a meeting of the Joint Committee is to be held on Wednesday next to consider the question of converting this railway to electric traction.

Chiswick Electric Supply Corporation.—There was a net profit of £3,934 for 1910, and a dividend at the rate of 6 per cent. for the year is recommended on the ordinary shares. The report makes reference to the satisfactory results which have been obtained with the Diesel engine plant by the Aberystwyth Company, in which concern the Chiswick Company holds the controlling interest.

Electric Cranes.—In a Paper read before the Institution of Engineers & Shipbuilders in Scotland on April 18th, Mr. R. Boyle gave particulars and illustrations of a large number of electric cranes, with lifting capacities of from 150 to 200 tons. The Paper dealt mainly with the mechanical features, and examples of derrick, portal jib, floating, tower, hammerhead, and giant cantilever cranes were described. A typical equipment for a 150-ton revolving cantilever crane is given as follows:—Two 50-b.h.p. main hoist motors, with series parallel control arranged for nine steps on both lighting and lowering, five series and four parallel steps. Overwinding switch, rheostatic, hydraulic, and band brakes.—One auxiliary hoist motor of 50 h.p., with seven steps on hoisting, three for lowering, and four braking steps, rheostatic and band brakes.—One main rack motor of 50 h.p., with seven steps out or in and three braking steps each way. Minimum and maximum radius switch, rheostatic and band brakes.—One 50-b.h.p. slewing motor, with seven power steps and three braking steps on each side, also rheostatic and band brakes.—One jigger hoist motor, with five power steps on the hoisting side and two on the lowering side, four braking steps, overwinding switch, and rheostatic and band brakes.—One jigger-rack motor, with five points of control in or out, and two braking steps.

SILVERTOWN "Z" TYPE MOTORS

1—1½ B.H.P.

AN IMPORTANT FEATURE

As with all other types of Silvertown Motors, every "Z" Machine is guaranteed to develop its rated output.

SILVERTOWN MOTORS are liberally designed, and give satisfactory service—always.

The Prices are competitive. Full particulars on application.
